## 1. Introduction

---

The NXP LPC315x combine an 180 MHz ARM926EJ-S CPU core, High-speed USB 2.0 OTG, 192 KB SRAM, NAND flash controller, flexible external bus interface, an integrated audio codec, Li-ion charger, Real-Time Clock (RTC), and a myriad of serial and parallel interfaces in a single chip targeted at consumer, industrial, medical, and communication markets. To optimize system power consumption, the LPC315x have multiple power domains and a very flexible Clock Generation Unit (CGU) that provides dynamic clock gating and scaling.

The LPC315x is implemented as multi-chip module with two side-by-side dies, one for digital functions and one for analog functions, which include a Power Supply Unit (PSU), audio codec, RTC, and Li-ion battery charger.

## 2. Features

---

### 2.1 General features

- Low power consumption.
- Supports SLC and MLC NAND flash memory devices ranging in size between 128 MB to 16 GB.
- Available in small footprint package TFBGA208 of 12 x 12 sqmm with 0.7 mm pitch.
- Built-in support for Li-ion cell with integrated charger.
- Provides sufficient processing power for audio post processing features and audio enhancement algorithms.
- Supports FM radio input including low-power audio bypass mode.

### 2.2 Hardware features

- ARM926EJ-S processor core with 16 kB data cache and 16 kB instruction cache running at frequencies of up to 180 MHz (CPU)/ 90 MHz (bus).
- 192 kB embedded SRAM implemented as two separate slaves on the AHB bus of 96 kB each.
- Embedded ROM memory to support booting from SPI flash, NAND flash, SD/MMC cards, UART, and USB.
- Integrated NAND flash controller with 8-symbol Error Correction (ECC) and AES decryption support (LPC3154 only). This controller supports up to four NAND flash devices which can be any combination of SLC type NAND flash and MLC type NAND flash up to a capacity of 16 GB.
- AES decryption engine (LPC3154 only).
- Multi-Port Memory Controller (MPMC) with one synchronous memory chip select for SDRAM memory (supports up to 128 MB) and two static memory chip selects for memory mapped devices (supports up to 128 kB each).

- Integrated USB 2.0 High Speed OTG interface.
- Embedded DMA controller with burst transfer support.
- Digital interfaces:
  - Integrated 4/8/16-bit 6800/8080 compatible LCD interface with DMA support.
  - General-purpose IO pins (nearly all digital pins can be configured as GPIO pins).
  - Integrated Master/Slave SPI interface with DMA support.
  - Two I<sup>2</sup>S interfaces.
  - Integrated fast UART with DMA support, IrDA, and hardware flow control.
  - Two Master/Slave I<sup>2</sup>C interfaces with open-drain port pins.
  - Pulse Code Modulation (PCM) and ISDN Oriented Modular (IOM) Interface (IPINT).
  - Memory Card Interface (MCI) with MMC/SDIO/SD/CE-ATA.
- Analog interfaces:
  - Built-in 10-bit ADC for level measurement and control (three inputs available on external pins and one internal input to measure the battery level).
  - Integrated stereo ADC with programmable amplifier (microphone, line input, and tuner input).
  - Integrated Class AB headphone amplifier.
  - Integrated stereo digital-to-analog converter with Class AB headphone amplifier for high quality audio with increased driving capabilities and for use in tuner applications.
  - Low-power tuner mode with direct connection between tuner input and Class AB headphone amplifier with analog volume control.
  - Power Supply Unit (PSU).
  - Li-ion battery charger.
  - USB\_VBUS charge pump in host mode.
- Four integrated general-purpose timers.
- Supports secure code execution and advanced DRM schemes:
  - Random Number Generator.
  - Secure one-time programmable memory for AES key storage or customer use.
- Integrated watchdog timer.
- Real-Time Clock (RTC) with separate power domain and dedicated 32 kHz oscillator.
- JTAG interface with boundary scan and ARM debug access.

### 3. Ordering information

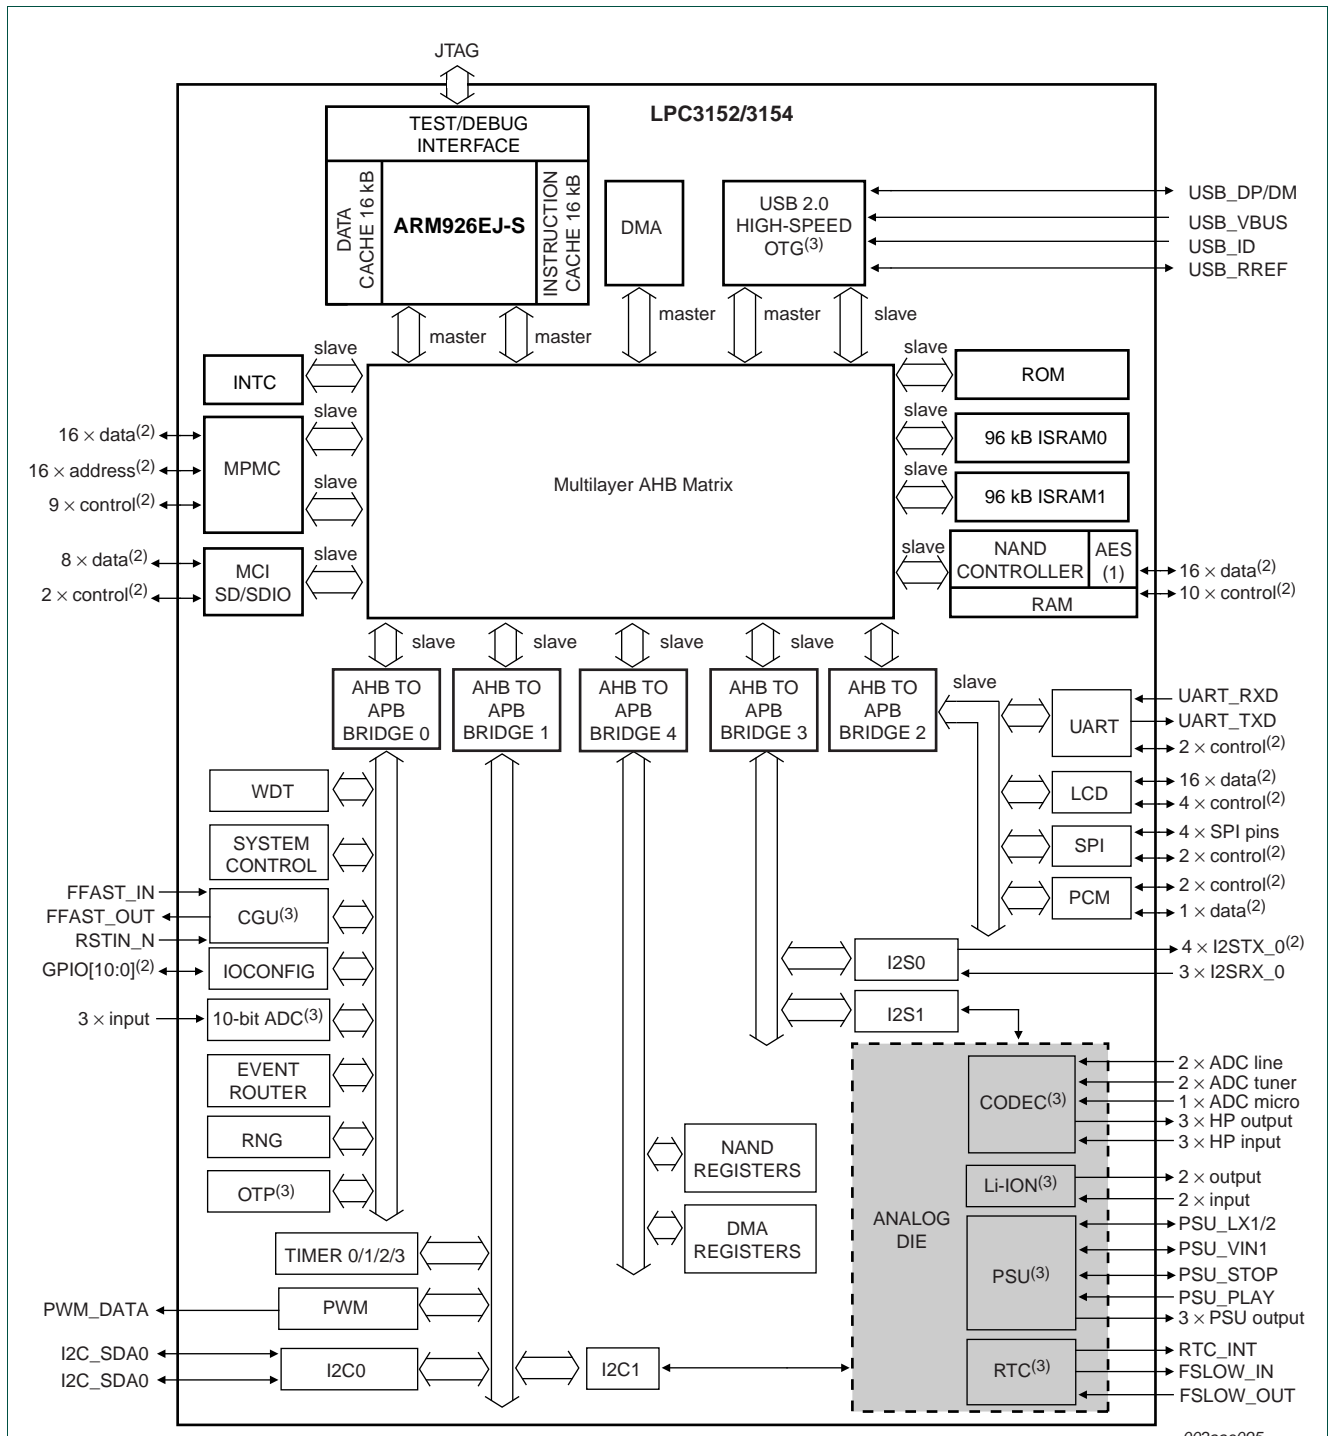

Table 1. Ordering information

Type number	Package		Version
	Name	Description	
LPC3152	TFBGA208	TFBGA208: plastic thin fine-pitch ball grid array package; 208 balls; body 12 x 12 x 0.7 mm	sot930-1
LPC3154	TFBGA208	TFBGA208: plastic thin fine-pitch ball grid array package; 208 balls; body 12 x 12 x 0.7 mm	sot930-1

Table 2. Ordering options for LPC3152/54

Type number	Total SRAM	NAND Flash Controller	Security engine AES	High-speed USB	10-bit ADC channels	Stereo ADC/ DAC, PSU, RTC, Li-ion charger	MCI SDHC/ SDIO/ CE_ATA	Pins	Temperature range
LPC3152	192 kB	yes	no	Device/ Host/OTG	3	yes	yes	208	-40 °C to +85 °C
LPC3154	192 kB	yes	yes	Device/ Host/OTG	3	yes	yes	208	-40 °C to +85 °C

4. Block diagram (LPC3152/54)

- (1) AES encryption engine available in LPC3154 only.
- (2) Multiplexed pins.
- (3) Supply and ground pins are not shown in this block diagram.

Fig 1. LPC3152/54 block diagram

## 5. Architectural overview

---

### 5.1 ARM926EJ-S

The processor embedded in the LPC315x is the ARM926EJ-S. It is a member of the ARM9 family of general-purpose microprocessors. The ARM926EJ-S is intended for multi-tasking applications where full memory management, high performance, and low power are important.

The CPU has the following features:

- ARM926EJ-S processor core which uses a five-stage pipeline consisting of fetch, decode, execute, memory, and write stages. The processor supports both the 32-bit ARM and 16-bit Thumb instruction sets, which allows a trade off between high performance and high code density. The ARM926EJ-S also executes an extended ARMv5TE instruction set which includes support for Java byte code execution.
- Contains an AMBA BIU for both data accesses and instruction fetches.
- Memory Management Unit (MMU).
- 16 kB instruction and 16 kB data separate cache memories with an 8 word line length. The caches are organized using Harvard architecture.
- Little Endian is supported.
- The ARM926EJ-S processor supports the ARM debug architecture and includes logic to assist in both hardware and software debugging.
- Supports dynamic clock gating for power reduction.
- The processor core clock can be set equal to the AHB bus clock or to an integer number times the AHB bus clock. The processor can be switched dynamically between these settings.
- ARM stall support.

### 5.2 Internal ROM Memory

The internal ROM memory is used to store the boot code of the LPC315x. After a reset, the ARM processor will start its code execution from this memory.

The LPC315x ROM memory has the following features:

- Supports booting from SPI flash, NAND flash, SD/SDHC/MMC cards, UART, and USB (DFU class) interfaces.
- Supports option to perform CRC32 checking on the boot image.
- Supports booting from managed NAND devices such as moviNAND, iNAND, eMMC-NAND and eSD-NAND using SD/MMC boot mode.
- Contains pre-defined MMU table (16 kB) for simple systems.

### 5.3 Internal RAM memory

The ISRAM (Internal Static Memory Controller) module is used as controller between the AHB bus and the internal RAM memory. The internal RAM memory can be used as working memory for the ARM processor and as temporary storage to execute the code that is loaded by boot ROM from external devices such as SPI-flash, NAND flash, and SD/MMC cards.

This module has the following features:

- Capacity of 192 kB
- Implemented as two independent 96 kB memory banks

### 1. How to read this chapter

The AES block is available on the LPC3154 only. See [Table 2–3](#) for clocks and registers that are specific to the AES block and are therefore not available in LPC3152.

**Table 3. Part specific clocks and registers**

Clock signal or register	Description	LPC3152	LPC3154
NANDFLASH_AES_CLK	NAND flash AES clock	no	yes
NandAESKey1-4	Words 1 to 4 of 128-bit AES key	no	yes
NandAESIV1-4	Words 1 to 4 of 128-bit initial AES value	no	yes
NandAESState	Register to display AES state	no	yes
Interrupt registers: NandIRQStatus1, NandIRQMask1, NandIRQStatusRaw1	AES related interrupt status, mask, and raw status bits INT0/1S, INT0/1M, and INT0/1R	no	yes
NandConfig	AO bit: turns AES on/off	no	yes
AES_FROM_AHB	Enable AES engine access from AHB	no	yes

### 2. Introduction

The NAND flash controller is used to transfer data between the LPC315x and external NAND flash devices.

#### 2.1 Features

- AHB/APB interface
  - AHB slave interface.
  - AHB interface supports 0,1 and 2 wait states.
  - Two SRAMs of 132 words, 32 bits per word used in a double buffering accessible via the AHB bus. RAM0 at 0x7000 0000 and RAM1 at 0x7000 0400.
  - Programming by CPU via APB interface using zero wait states.
  - Little and big endian support.
  - Automatic flow control with the DMA controller, using ext\_en/ext\_ack signals.
- NAND flash support
  - Dedicated interface to NAND flash devices.
  - Hardware controlled read and write data transfers.
  - Software controlled command and address transfers to support a wide range of NAND flash devices.
  - GPIO mode.
  - Software control mode where the ARM is directly master of the NAND flash device.
  - Support for 8 bit and 16 bit NAND flash devices.

- Support for 528 byte, 2K and 4K page NAND flash devices.
- Programmable NAND timing parameters.
- Support for up to 4 NAND flash device dies in parallel with dedicated chip select and ready/busy pin per device.
- Programmable default state of output signals.
- Erased page detection.
- EBI compatible.
- Error correction
  - Two Reed-Solomon error correction codes, one offering 5 symbol error correction and the other 8 symbol error correction capability. 5 symbol correcting code is of length 469, dimension 459, and minimum distance 11 over GF(2<sup>9</sup>). 8 symbol correcting code has length 475, dimension 459 and minimum distance 17 over GF(2<sup>9</sup>).
  - Two parity generators.
  - Wear leveling and other extra information can be integrated into protected data.
 

**Remark:** The wear-leveling algorithm ensures that data is stored in different flash pages across the flash media. This not only extends its lifetime, but also ensures reliable operation.
  - Interrupts generated after completion of error correction task with 3 interrupt registers.
  - Error correction statistics distributed to ARM using interrupt scheme.
  - Error correction can be turned on and off.
- AES decryption
  - AES-128 : 128-bit key, 128-bit data.
  - CBC mode over blocks of 512 bytes.
  - Initial vector and key can be programmed over APB.
  - Each block of 512 bytes uses same initial value.
  - AES can be turned on and off.

### 3. General description

#### 3.1 Clock signals

The CGU provides different clocks to the NAND flash controller, see [Table 2–4](#).

**Table 4. NAND flash controller clock overview<sup>[1]</sup>**

Clock name	Clock acronym	I/O	Source/ Destination	Description
NANDFLASH_S0_CLK	ahb_clk	I	CGU	AHB port clock of the module
NANDFLASH_PCLK	PCLK	I	CGU	APB port clock of the module

**Table 4. NAND flash controller clock overview**<sup>[1]</sup> ...continued

Clock name	Clock acronym	I/O	Source/ Destination	Description
NANDFLASH_NAND_CLK	nand_clk	I	CGU	Main clock for the module
NANDFLASH_ECC_CLK	ecc_clk	I	CGU	Main clock for ECC part in the module. This clock should be programmed to run synchronously at half the NANDFLASH_NAND_CLK in CGU block.
NANDFLASH_AES_CLK	aes_clk	I	CGU	Main clock for AES part in the module. This clock should be programmed to run synchronously at the same speed as the NANDFLASH_NAND_CLK in CGU block.

[1] See [Table 2–3](#) for clocks that are part specific and not implemented on all LPC315x parts.

### 3.2 Reset signals

The CGU provides the following resets to the NAND flash controller (see [Section 13–5.2.2](#)).

1. AHB0\_RESET: Low-active, synchronous reset. Resets the logic in the ahb\_clk domain.
2. APB4\_RESETN: Low-active, synchronous reset. Resets the logic in the PCLK domain.
3. NANDFLASH\_CTRL\_NAND\_RESET\_N: High-active, synchronous reset. Resets the logic in the main NAND flash controller nand\_clk domain.
4. NANDFLASH\_CTRL\_ECC\_RESET\_N: High-active, synchronous reset. Resets the logic in the ecc\_clk domain.
5. NANDFLASH\_CTRL\_AES\_RESET\_N: High-active, synchronous reset. Resets the logic in the aes\_clk domain.

### 3.3 Interrupt requests

The NAND flash controller generates one interrupt request towards the CPU. The interrupt sources are controlled by two sets of registers: NandIRQStatus1, NandIRQMask1, NandIRQStatusRaw1 and NandIRQStatus2, NandIRQMask2, NandIRQStatusRaw2. See [Table 2–7](#) to [Table 2–9](#) and [Table 2–23](#) to [Table 2–25](#) for a description of interrupt sources.

### 3.4 DMA transfers

The NAND flash controller has DMA support by means of external enabling. The transfer size is 128 words. DMA auto-flow control is supported only by DMA channel 4.

### 3.5 External pin connections

[Table 2–5](#) gives an overview of the external connections to and from the NAND flash controller.

**Table 5. NAND flash controller external pin overview**

Pin name	Interface	Acronym	Type (Func.)	Reset Value	Description
EBI_D_[15:0]	EBI	-	I	-	16 bits data from NAND flash device
EBI_D_[15:0]	EBI	-	O	all 0	16 bits data to NAND flash device
NAND_NCS_0		CS1_n	O	1	Low-active Chip Enable 0
NAND_NCS_1		CS2_n	O	1	Low-active Chip Enable 1
NAND_NCS_2		CS3_n	O	1	Low-active Chip Enable 2
NAND_NCS_3		CS4_n	O	1	Low-active Chip Enable 3
EBI_NWE	EBI	WE_n	O	1	Low-active Write Enable
EBI_DQM_0_NOE	EBI	RE_n	O	1	Low-active Read Enable
EBI_A_0_ALE	EBI	ALE	O	0	High-active Address Latch Enable
EBI_A_1_CLE	EBI	CLE	O	0	High-active Command Latch Enable
mNAND_RYBN0		RnB0	I	-	Ready not Busy 0
mNAND_RYBN1		RnB1	I	-	Ready not Busy 1
mNAND_RYBN2		RnB2	I	-	Ready not Busy 2
mNAND_RYBN3		RnB3	I	-	Ready not Busy 3

## 4. Register overview

[Table 2–6](#) indicates which registers reside in the NAND flash controller. The NAND RAM buffers are also accessible at locations RAM0: 0x7000 0000 and RAM1: 0x7000 0400.

**Table 6. Register overview: NAND flash controller (register base address: 0x1700 0800)**[\[1\]](#)

Name	Access	Offset	Description
NandIRQStatus1	R/W	0x00	Status register of first 32 bits interrupt register
NandIRQMask1	R/W	0x04	Mask register for first 32 bits interrupt register
NandIRQStatusRaw1	R/W	0x08	Unmasked status register of first 32 bits interrupt register
NandConfig	R/W	0x0C	NAND flash controller configuration register
NandIOConfig	R/W	0x10	Register which holds the default value settings for IO signals
NandTiming1	R/W	0x14	First NAND flash controller timing register
NandTiming2	R/W	0x18	Second NAND flash controller timing register
NandSetCmd	R/W	0x20	Register to send specific command towards NAND flash device.
NandSetAddr	R/W	0x24	Register to send specific address towards NAND flash device
NandWriteData	R/W	0x28	Register to send specific data towards NAND flash device
NandSetCE	R/W	0x2C	Register to set all CE signals and WP_n signal
NandReadData	R	0x30	Register to check read data from NAND flash device

**Table 6. Register overview: NAND flash controller (register base address: 0x1700 0800)**<sup>[1]</sup>

Name	Access	Offset	Description
NandCheckSTS	R	0x34	Check status of 8 predefined interrupts
NandControlFlow	W	0x38	Register which holds command to read and write pages
NandGPIO1	R/W	0x40	Register to program IO pins, which can be used as GPIO
NandGPIO2	R	0x44	Register to program IO pins, which can be used as GPIO
NandIRQStatus2	R/W	0x48	Status register of second 32 bits interrupt register
NandIRQMask2	R/W	0x4C	Mask register for second 32 bits interrupt register
NandIRQStatusRaw2	R/W	0x50	Unmasked status register of second 32 bits interrupt register
NandAESKey1	W	0x54	First word of 128-bit AES key
NandAESKey2	W	0x58	Second word of 128-bit AES key
NandAESKey3	W	0x5C	Third word of 128-bit AES key
NandAESKey4	W	0x60	Fourth word of 128-bit AES key
NandAESIV1	W	0x64	First word of 128-bit initial AES value
NandAESIV2	W	0x68	Second word of 128-bit initial AES value
NandAESIV3	W	0x6C	Third word of 128-bit initial AES value
NandAESIV4	W	0x70	Fourth word of 128-bit initial AES value
NandAESState	R/W	0x74	Register to display AES state
NandECCErrStatus	R	0x78	ECC error status register in 8-symbol ECC mode
AES_FROM_AHB	R/W	0x7C	Enable AES engine from AHB

[1] See [Table 2–3](#) for registers that are part specific and not implemented on all LPC315x parts.

## 5. Register description

### 5.1 NandIRQStatus1

In this register the status of the different interrupt sources can be checked. All interrupts can be masked by the corresponding bit in the NandIRQMask register. A bit which has been set can only be cleared by writing a '1' to this bit in this register. [Table 2–7](#) gives a description of this register.

**Table 7. NandIRQStatus1 register description (NandIRQStatus1, address 0x1700 0800)**

Bit	Symbol	Access	Reset value	Description
31	INT31S	R/W	0x0	mNAND_RYBN3 positive edge. Asserted after a positive edge of the mNAND_RYBN3 signal.
30	INT30S	R/W	0x0	mNAND_RYBN2 positive edge. Asserted after a positive edge of the mNAND_RYBN2 signal.
29	INT29S	R/W	0x0	mNAND_RYBN1 positive edge. Asserted after a positive edge of the mNAND_RYBN1 signal.
28	INT28S	R/W	0x0	mNAND_RYBN0 positive edge. Asserted after a positive edge of the mNAND_RYBN0 signal.
27	INT27S	R/W	0x0	RAM 1 erased. Whenever an erased page is read from flash (all 0xFF) this bit is asserted together with read page1 done.

Table 7. NandIRQStatus1 register description (NandIRQStatus1, address 0x1700 0800)

Bit	Symbol	Access	Reset value	Description
26	INT26S	R/W	0x0	RAM 0 erased. Whenever an erased page is read from flash (all 0xFF) this bit is asserted together with read page0 done.
25	INT25S	R/W	0x0	Write page 1 done. Asserted when SRAM1 contents has been written to the flash.
24	INT24S	R/W	0x0	Write page 0 done. Asserted when SRAM0 contents has been written to the flash.
23	INT23S	R/W	0x0	Read page 1 done. Asserted when SRAM1 contents has been read from flash and stored in SRAM1 (not error corrected yet).
22	INT22S	R/W	0x0	Read page 0 done. Asserted when SRAM0 contents has been read from flash and stored in SRAM0 (not error corrected yet).
21	INT21S	R/W	0x0	RAM 0 decoded. Asserted when the contents of SRAM0 has been decoded. Each time bit21 or bit19 are activated, one other bit will be activated too from the group Bit17-4 that indicates how many errors were detected in the current code word.
20	INT20S	R/W	0x0	RAM 0 encoded. Asserted when the contents of SRAM0 has been encoded.
19	INT19S	R/W	0x0	RAM 1 decoded. Asserted when the contents of SRAM1 has been decoded. Each time bit21 or bit19 are activated, one other bit will be activated too from the group Bit17-4 that indicates how many errors were detected in the current code word.
18	INT18S	R/W	0x0	RAM 1 encoded. Asserted when the contents of SRAM1 has been encoded.
17	INT17S	R/W	0x0	RAM 0 decoded with 0 errors
16	INT16S	R/W	0x0	In 5bit ECC mode, this interrupt bit is set when a codeword with one error is detected.  In 8bit ECC mode, this interrupt bit is set when a codeword with at least one correctable error is detected. The number of errors can then be extracted from the NandEccErrStatus(0x78) register.
15	INT15S	R/W	0x0	RAM 0 decoded with 2 error
14	INT14S	R/W	0x0	RAM 0 decoded with 3 error
13	INT13S	R/W	0x0	RAM 0 decoded with 4 error
12	INT12S	R/W	0x0	RAM 0 decoded with 5 error
11	INT11S	R/W	0x0	RAM 0 uncorrectable
10	INT10S	R/W	0x0	RAM 1 decoded with 0 errors
9	INT9S	R/W	0x0	In 5bit ECC mode, this interrupt bit is set when a codeword with one error is detected.  In 8bit ECC mode, this interrupt bit is set when a codeword with at least one correctable error is detected. The number of errors can then be extracted from the NandEccErrStatus(0x78) register.
8	INT8S	R/W	0x0	RAM 1 decoded with 2 error
7	INT7S	R/W	0x0	RAM 1 decoded with 3 error
6	INT6S	R/W	0x0	RAM 1 decoded with 4 error
5	INT5S	R/W	0x0	RAM 1 decoded with 5 error
4	INT4S	R/W	0x0	RAM 1 uncorrectable

**Table 7. NandIRQStatus1 register description (NandIRQStatus1, address 0x1700 0800)**

Bit	Symbol	Access	Reset value	Description
3:2	-	-	-	Reserved
1	INT1S	R/W	0x0	RAM 1 AES done. Asserted when the contents of SRAM1 has been AES decoded.
0	INT0S	R/W	0x0	RAM 0 AES done. Asserted when the contents of SRAM0 has been AES decoded.

## 5.2 NandIRQMask1

Each bit in this register field masks the corresponding interrupt bit in the NandIRQStatus register. [Table 2-7](#) gives a description of this register.

**Table 8. NandIRQMask1 register description (NandIRQMask1, address 0x1700 0804)**

Bit	Symbol	Access	Reset Value	Description
31	INT31M	R/W	0x1	mNAND_RYBN3 positive edge mask
30	INT30M	R/W	0x1	mNAND_RYBN2 positive edge mask
29	INT29M	R/W	0x1	mNAND_RYBN1 positive edge mask
28	INT28M	R/W	0x1	mNAND_RYBN0 positive edge mask
27	INT27M	R/W	0x1	RAM 1 erased mask
26	INT26M	R/W	0x1	RAM 0 erased mask
25	INT25M	R/W	0x1	Write page 1 done mask
24	INT24M	R/W	0x1	Write page 0 done mask
23	INT23M	R/W	0x1	Read page 1 done mask
22	INT22M	R/W	0x1	Read page 0 done mask
21	INT21M	R/W	0x1	RAM 0 decoded mask
20	INT20M	R/W	0x1	RAM 0 encoded mask
19	INT19M	R/W	0x1	RAM 1 decoded mask
18	INT18M	R/W	0x1	RAM 1 encoded mask
17	INT17M	R/W	0x1	RAM 0 decoded with 0 errors mask
16	INT16M	R/W	0x1	RAM 0 decoded with 1 error mask
15	INT15M	R/W	0x1	RAM 0 decoded with 2 error mask
14	INT14M	R/W	0x1	RAM 0 decoded with 3 error mask
13	INT13M	R/W	0x1	RAM 0 decoded with 4 error mask
12	INT12M	R/W	0x1	RAM 0 decoded with 5 error mask
11	INT11M	R/W	0x1	RAM 0 uncorrectable mask
10	INT10M	R/W	0x1	RAM 1 decoded with 0 errors mask
9	INT9M	R/W	0x1	RAM 1 decoded with 1 error mask
8	INT8M	R/W	0x1	RAM 1 decoded with 2 error mask
7	INT7M	R/W	0x1	RAM 1 decoded with 3 error mask
6	INT6M	R/W	0x1	RAM 1 decoded with 4 error mask
5	INT5M	R/W	0x1	RAM 1 decoded with 5 error mask
4	INT4M	R/W	0x1	RAM 1 uncorrectable mask

**Table 8. NandIRQMask1 register description (NandIRQMask1, address 0x1700 0804)**

Bit	Symbol	Access	Reset Value	Description
3:2	-	-	-	Reserved
1	INT1M	R/W	0x1	RAM 1 AES done mask
0	INT0M	R/W	0x1	RAM 0 AES done mask

### 5.3 NandIRQStatusRaw1

In this register the status of the different interrupt sources can be checked without masking. A bit which has been set can only be cleared by writing a '1' to this bit in this register. [Table 2-9](#) gives a description of this register.

**Table 9. NandIRQStatusRaw1 register description (NandIRQStatusRaw1, address 0x1700 0808)**

Bit	Symbol	Access	Reset value	Description
31	INT31R	R/W	0x0	mNAND_RYBN3 positive edge raw value
30	INT30R	R/W	0x0	mNAND_RYBN2 positive edge raw value
29	INT29R	R/W	0x0	mNAND_RYBN1 positive edge raw value
28	INT28R	R/W	0x0	mNAND_RYBN0 positive edge raw value
27	INT27R	R/W	0x0	RAM 1 erased raw value
26	INT26R	R/W	0x0	RAM 0 erased raw value
25	INT25R	R/W	0x0	Write page 1 done raw value
24	INT24R	R/W	0x0	Write page 0 done raw value
23	INT23R	R/W	0x0	Read page 1 done raw value
22	INT22R	R/W	0x0	Read page 0 done raw value
21	INT21R	R/W	0x0	RAM 0 decoded raw value
20	INT20R	R/W	0x0	RAM 0 encoded raw value
19	INT19R	R/W	0x0	RAM 1 decoded raw value
18	INT18R	R/W	0x0	RAM 1 encoded raw value
17	INT17R	R/W	0x0	RAM 0 decoded with 0 errors raw value
16	INT16R	R/W	0x0	RAM 0 decoded with 1 error raw value
15	INT15R	R/W	0x0	RAM 0 decoded with 2 error raw value
14	INT14R	R/W	0x0	RAM 0 decoded with 3 error raw value
13	INT13R	R/W	0x0	RAM 0 decoded with 4 error raw value
12	INT12R	R/W	0x0	RAM 0 decoded with 5 error raw value
11	INT11R	R/W	0x0	RAM 0 uncorrectable raw value
10	INT10R	R/W	0x0	RAM 1 decoded with 0 errors raw value
9	INT9R	R/W	0x0	RAM 1 decoded with 1 error raw value
8	INT8R	R/W	0x0	RAM 1 decoded with 2 error raw value
7	INT7R	R/W	0x0	RAM 1 decoded with 3 error raw value
6	INT6R	R/W	0x0	RAM 1 decoded with 4 error raw value
5	INT5R	R/W	0x0	RAM 1 decoded with 5 error raw value

**Table 9.** NandIRQStatusRaw1 register description (NandIRQStatusRaw1, address 0x1700 0808) ...continued

Bit	Symbol	Access	Reset value	Description
4	INT4R	R/W	0x0	RAM 1 uncorrectable raw value
3:2	-	-	-	Reserved
1	INT1R	R/W	0x0	RAM 1 AES done raw value
0	INT0R	R/W	0x0	RAM 0 AES done raw value

## 5.4 NandConfig

This register is used to configure the NAND flash controller. [Table 2–10](#) gives a description of this register.

**Table 10.** NandConfig register description (NandConfig, address 0x1700 080C)

Bit	Symbol	Access	Reset value	Description
31:13	-	-	-	reserved
12	ECC_MODE	R/W	0x0	ECC mode 0: 5 bit ECC mode selected. 1: 8 bit ECC mode selected.
11:10	TL	R/W	0x0	Transfer limit, determines the number of bytes written/read to the NAND flash in one step. 00/11: 528 bytes 01: 516 bytes 10: 512 bytes
9	-	-	-	reserved
8	DC	R/W	0x1	Deactivate CE enable 0: When the NAND flash is forced off the EBI bus by a backoff signal, the CE is not deactivated. 1: When the NAND flash is forced off the EBI bus by a backoff signal, the CE is deactivated.
7	M	R/W	0x0	512 mode 0 : The ECC encoding is started automatically after programming byte 516 in the SRAM. To be used when byte 513-516 need to be written to the flash (previous data will be written in this field). 1 : The ECC encoding is started automatically after programming byte 512 in the SRAM. To be used when byte 513-516 do not need to be written to the flash (previous data will be written in this field).
6:5	LC	R/W	0x0	Latency Configuration 0x0 : zero wait states 0x1 : one wait state 0x2 : two wait states
4	ES	R/W	0x0	Endianess setting 0 : little endian 1 : big endian

**Table 10. NandConfig register description (NandConfig, address 0x1700 080C)**

Bit	Symbol	Access	Reset value	Description
3	DE	R/W	0x0	DMA external enable 0: disables the automatic flow control with DMA. 1: enables the automatic flow control with DMA.
2	AO	R/W	0x0	AES on 0 : AES decryption off 1 : AES decryption on
1	WD	R/W	0x0	Wide device 0 : 8 bit NAND device mode 1 : 16 bit NAND device mode
0	EC	R/W	0x0	ECC on 0 : error correction off 1 : error correction on

## 5.5 NandIOConfig

This register defines the default values of the outputs to the NAND flash device. Default values are put on the outputs when the NAND flash controller is in idle state. [Table 2–11](#) gives a description of this register.

**Table 11. NandIOConfig register description (NandIOConfig, address 0x1700 0810)**

Bit	Symbol	Access	Reset	Description
31:25	-	-	-	Reserved
24	NI	R/W	0x0	Nand IO drive default 0 : IO pad is in input mode 1 : IO pad is in output mode, data is driven on the pads.
23:8	DN	R/W	0x0	Data to NAND default data_to_nand[15:0] value
7:6	CD	R/W	0x0	CLE default "00" : '0' other values : '1'
5:4	AD	R/W	0x0	ALE default "00" : '0' other values : '1'
3:2	WD	R/W	0x1	WE_n default "00" : '0' other values : '1'
1:0	RD	R/W	0x1	RE_n default "00" : '0' other values : '1'

## 5.6 NandTiming1

In this register the first set of NAND interface timing characteristics can be programmed. Each timing parameter can be set from 7 `nand_clk` (NANDFLASH\_NAND\_CLK) clock cycles to 1 `nand_clk` clock cycle. (A programmed zero value is treated as a one).

[Table 2–12](#) gives a description of this register.

Using `tSRD` and `tDRD` the data input circuitry can be tuned for optimal performance. Using the lower bit of these parameters one can select between clocking in on the positive edge of `nand_clk` or on the negative edge. The remaining bit(s) add extra `nand_clk` delay cycles to the data clock-in moment.

**Table 12. NandTiming1 register description (NandTiming1, address 0x1700 0814)**

Bit	Symbol	Access	Reset value	Description
31:22	-	-	-	Reserved
21:20	TSRD	R/W	0x0	Single data input delay The number of clock cycles between the rising edge of the RE signal and the cycle that the data is clocked in by the controller in case of software controlled single read access
19	-	-	-	Reserved
18:16	TALS	R/W	0x7	Address setup time The number of clock cycles between the rising edge of ALE and the falling edge of WE during a command transfer
15	-	-	-	Reserved
14:12	TALH	R/W	0x7	Address hold time The number of clock cycles that ALE remains asserted after the rising edge of WE
11:7	-	-	-	Reserved
6:4	TCLS	R/W	0x7	Command setup time The number of clock cycles between the rising edge of CLE and the falling edge of WE during a command transfer
3	-	-	-	Reserved
2:0	TCLH	R/W	0x7	Command hold time The number of clock cycles that CLE remains asserted after the rising edge of WE

## 5.7 NandTiming 2

In this register the second set of NAND interface timing characteristics can be programmed. Each timing parameter can be set from 7 `nand_clk` clock cycles to 1 `nand_clk` clock cycle. (A programmed zero value is treated as a one). [Table 2–13](#) gives a description of this register.

**Table 13. NandTiming2 register description (NandTiming2, address 0x1700 0818)**

Bit	Symbol	Access	Reset value	Description
31	-	-	-	Reserved
30:28	TDRD	R/W	0x0	Data input delay The number of clock cycles between the rising edge of the RE signal and the cycle that the data is clocked in by the controller in case of hardware controlled burst read access
27	-	-	-	Reserved
26:24	TEBIDEL	R/W	0x7	EBI delay time The number of clock cycles between the rising edge of CS and the falling edge of ebireq when backing off from the EBI. OR The number of clock cycles between the rising edge of ebignt and the falling edge of CS when going on the EBI.
23	-	-	-	Reserved
22:20	TCH	R/W	0x7	Chip select hold time The number of clock cycles between the last active signal to the NAND flash and the rising edge of CS
19	-	-	-	Reserved
18:16	TCS	R/W	0x7	Chip select setup time The number of clock cycles between the falling edge of CS and the first active signal to the NAND flash
15	-	-	-	Reserved
14:12	TREH	R/W	0x7	Read enable high hold The minimum number of clock cycles that the RE pulse is held
11	-	-	-	Reserved
10:8	TRP	R/W	0x7	Read enable pulse width The number of clock cycles that the RE pulse is de-asserted
7	-	-	-	Reserved
6:4	TWH	R/W	0x7	Write enable high hold The minimum number of clock cycles that the WE pulse is held high before a next falling edge
3	-	-	-	Reserved
2:0	TWP	R/W	0x7	Write enable pulse width The number of clock cycles that the WE pulse is de-asserted. This value also covers the tDS, (data setup time) since the data is set up on the I/O line at the same moment as the falling edge of the WE pulse

## 5.8 NandSetCmd

This register is used to transfer a command towards the NAND flash device. [Table 2–14](#) gives a description of this register.

**Table 14. NandSetCmd register description (NandSetCmd, address 0x1700 0820)**

Bit	Symbol	Access	Reset	Description
31:16	-	-	-	Reserved
15:0	CV	W	0x0	Command value Writing to this register results in a CLE-WE combined sequence that transfers the programmed command value to the NAND flash using the required timings.

## 5.9 NandSetAddr

This register is used to transfer an address towards the NAND flash device. [Table 2–15](#) gives a description of this register.

**Table 15. NandSetAddr register description (NandSetAddr, address 0x1700 0824)**

Bit	Symbol	Access	Reset	Description
31:16	-	-	-	Reserved
15:0	AV	W	0x0	Address value Writing to this register results in a ALE-WE combined sequence that transfers the programmed address value to the NAND flash using the required timings..

## 5.10 NandWriteData

This register is used to write data towards the NAND flash device. [Table 2–16](#) gives a description of this register.

**Table 16. NandWriteData register description (NandWriteData, address 0x1700 0828)**

Bit	Symbol	Access	Reset	Description
31:16	-	-	-	Reserved
15:0	WV	W	0x0	Writing a value WV to this register results in a WE sequence that transfers the programmed write value to the NAND flash using the required timings.

## 5.11 NandSetCE

This register is used to set the values of WP\_n and NAND\_NCS\_0 to NAND\_NCS\_3. [Table 2–17](#) gives a description of this register.

**Table 17. NandSetCE register description (NandSetCE, address 0x1700 082C)**

Bit	Symbol	Access	Reset	Description
31:5	-	-	-	Reserved
4	WP	W	0x0	WP_n pin value Sets WP_n pin value
3:0	CEV	W	0x0	The active value of the 4 chip select outputs. The chip select outputs take on the values out of this register when the controller is not in idle state and the EBI bus is granted to the NAND controller. CE1_n = CEV(0) CE2_n = CEV(1) CE3_n = CEV(2) CE4_n = CEV(3)

## 5.12 NandReadData

This register is used to read data from the NAND flash device. [Table 2–18](#) gives a description of this register.

**Table 18. NandReadData register description (NandReadData, address 0x1700 0830)**

Bit	Symbol	Access	Reset	Description
31:16	-	-	-	Reserved
15:0	RV	W	0x0	Read value Reading this register results in a RE sequence that after the necessary wait states puts the retrieved value from the NAND IO port into the register..

## 5.13 NandCheckSTS

This register is used to read out the status of the NAND flash controller, w.r.t. the values on the incoming RnB signals. Next to that the busy state of the APB can be checked. [Table 2–19](#) gives a description of this register.

**Table 19. NandCheckSTS register description (NandCheckSTS, address 0x1700 0834)**

Bit	Symbol	Access	Reset	Description
31:9	-	-	-	Reserved
8	R3R	R	0x0	mNAND_RYBN3 rising edge. 1: Rising edge on the mNAND_RYBN3 signal has been detected. Bit is reset to 0 upon read.
7	R2R	R	0x0	mNAND_RYBN2 rising edge. 1: Rising edge on the mNAND_RYBN2 signal has been detected. Bit is reset to 0 upon read.
6	R1R	R	0x0	mNAND_RYBN1 rising edge. 1: Rising edge on the mNAND_RYBN1 signal has been detected. Bit is reset to 0 upon read.

**Table 19. NandCheckSTS register description (NandCheckSTS, address 0x1700 0834)**

Bit	Symbol	Access	Reset	Description
5	R0R	R	0x0	mNAND_RYBN0 rising edge. 1: Rising edge on the mNAND_RYBN0 signal has been detected. Bit is reset to 0 upon read.
4	R3	R	0x0	mNAND_RYBN3 value. The sample value of the mNAND_RYBN3 signal from the flash.
3	R2	R	0x0	mNAND_RYBN2 value. The sample value of the mNAND_RYBN2 signal from the flash.
2	R1	R	0x0	mNAND_RYBN1 value. The sample value of the mNAND_RYBN1 signal from the flash.
1	R0	R	0x0	mNAND_RYBN0 value. The sample value of the mNAND_RYBN0 signal from the flash.
0	VB	R	0x0	APB busy 1: flash access over the APB bus is busy 0: no flash access over APB bus at this moment

### 5.14 NandControlFlow

This register is used to start the sequences for read page and write page operation. [Table 2–20](#) gives a description of this register.

**Table 20. NandControlFlow register description (NandControlFlow, address 0x1700 0838)**

Bit	Symbol	Access	Reset	Description
31:6	-	-	-	Reserved
5	W1	W	0x0	Writing a '1' to this property starts up the sequence to write the contents of SRAM1 to the NAND flash (if the contents has already been protected by the necessary parity symbols)
4	W0	W	0x0	Writing a '1' to this property starts up the sequence to write the contents of SRAM0 to the NAND flash (if the contents has already been protected by the necessary parity symbols)
3:2	-	-	-	Reserved
1	R1	W	0x0	Writing a '1' to this property starts up the sequence to read a defined number of bytes from the NAND flash and store them in SRAM1
0	R0	W	0x0	Writing a '1' to this property starts up the sequence to read a defined number of bytes from the NAND flash and store them in SRAM0

### 5.15 NandGPIO1

This register is used to program the IO pins in GPIO mode. [Table 2–21](#) gives a description of this register.

**Table 21. NandGPIO1 register overview (NandGPIO1, address 0x1700 0840)**

Bit	Symbol	Access	Reset	Description
31:27	-	-	-	Reserved
26	nand_gpio_conf	R/W	0x0	'0' : the module is in normal functional mode '1' : GPIO mode, the value of the outputs to the NAND flash can be controlled via NAND_GPIO1.
25	WP_n	R/W	0x0	Program value on WP_n
24	CLE	R/W	0x0	Program value on CLE
23	ALE	R/W	0x0	Program value on ALE
22	RE_n	R/W	0x1	Program value on RE_n
21	WE_n	R/W	0x1	Program value on WE_n
20	CE4_n	R/W	0x1	Program value on NAND_NCS_3
19	CE3_n	R/W	0x1	Program value on NAND_NCS_2
18	CE2_n	R/W	0x1	Program value on NAND_NCS_1
17	CE1_n	R/W	0x1	Program value on NAND_NCS_0
16	Nand io drive	R/W	0x0	Program value on Nand io drive
15:0	Data to NAND IO	R/W	0x0	Program value on data to Nand IO

### 5.16 NandGPIO2

In this register the value of the input signals from NAND can be monitored on read-out. [Table 2–22](#) gives a description of this register

**Table 22. NandGPIO2 register description (NandGPIO2, address 0x1700 0844)**

Bit	Symbol	Access	Reset	Description
31:20	-	-	-	Reserved
19	RnB3	R	0x0	Read value from mNAND_RYBN3
18	RnB2	R	0x0	Read value from mNAND_RYBN2
17	RnB1	R	0x0	Read value from mNAND_RYBN1
16	RnB0	R	0x0	Read value from mNAND_RYBN0
15:0	Data from NAND	R	0x0	Read data from NAND IO

### 5.17 NandIRQStatus2

In this register the status of the different interrupt sources can be checked. All interrupts can be masked by the corresponding bit in the NandIRQMask2 register. A bit which has been set can only be cleared by writing a '1' to this bit in this register. [Table 2–23](#) gives a description of this register.

**Table 23. NandIRQStatus2 register description (NandIRQStatus2, address 0x1700 0848)**

Bit	Symbol	Access	Reset	Description
31:5	-	-	-	Reserved
4	INT36S	R/W	0x0	Page access while APB access.
3	INT35S	R/W	0x0	APB access while page access.
2	INT34S	R/W	0x0	Flash access while busy.
1	INT33S	R/W	0x0	RAM1 access while busy.
0	INT32S	R/W	0x0	RAM0 access while busy.

## 5.18 NandIRQMask2

Each bit in this register field masks the corresponding interrupt bit in the NandIRQStatus2 register. [Table 2–24](#) gives a description of this register.

**Table 24. NandIRQMask2 register description (NandIRQMask2, address 0x1700 084C)**

Bit	Symbol	Access	Reset	Description
31:5	-	-	-	Reserved
4	INT36M	R/W	0x1	Page access while APB access masks
3	INT35M	R/W	0x1	APB access while page access mask
2	INT34M	R/W	0x1	Flash access while busy mask
1	INT33M	R/W	0x1	RAM1 access while busy mask
0	INT32M	R/W	0x1	RAM0 access while busy mask

## 5.19 NandIRQStatusRaw2

In this register the status of the different interrupt sources can be checked without masking. A bit which has been set can only be cleared by writing a '1' to this bit in this register. [Table 2–25](#) gives a description of this register.

**Table 25. NandIRQStatusRaw2 register description (NandIRQStatusRaw2, address 0x1700 0850)**

Bit	Symbol	Access	Reset	Description
31:5	-	-	-	Reserved
4	INT36R	R/W	0x0	Page access while APB access raw value.
3	INT35R	R/W	0x0	APB access while page access raw value.
2	INT34R	R/W	0x0	Flash access while busy raw value.
1	INT33R	R/W	0x0	RAM1 access while busy raw value.
0	INT32R	R/W	0x0	RAM0 access while busy raw value.

## 5.20 NandAESKey1

This register is used to store the first word of the 128-bit AES key. [Table 2–26](#) gives a description of this register.

**Table 26. NandAESKey1 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES key 1	R	0x0	First word of AES 128-bit key

### 5.21 NandAESKey2

This register is used to store the second word of the 128-bit AES key. [Table 2–27](#) gives a description of this register.

**Table 27. NandAESKey2 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES key 2	R	0x0	Second word of AES 128-bit key

### 5.22 NandAESKey3

This register is used to store the third word of the 128-bit AES key. [Table 2–28](#) gives a description of this register.

**Table 28. NandAESKey3 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES key 3	R	0x0	Third word of AES 128-bit key

### 5.23 NandAESKey4

This register is used to store the fourth word of the 128-bit AES key. [Table 2–29](#) gives a description of this register.

**Table 29. NandAESKey3 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES key 4	R	0x0	Fourth word of AES 128-bit key

### 5.24 NandAESIV1

This register is used to store the first word of the 128-bit AES initialization vector. [Table 2–30](#) gives a description of this register.

**Table 30. NandAESIV1 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES iv 1	R	0x0	First word of AES 128-bit initial value 128-bit vector

### 5.25 NandAESIV2

This register is used to store the second word of the 128-bit AES initialization vector. [Table 2–31](#) gives a description of this register.

**Table 31. NandAESIV2 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES iv 2	R	0x0	Second word of AES 128-bit initial value 128-bit vector

### 5.26 NandAESIV3

This register is used to store the third word of the 128-bit AES initialization vector. [Table 2–32](#) gives a description of this register.

**Table 32. NandAESIV3 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES iv 3	R	0x0	Third word of AES 128-bit initial value 128-bit vector

## 5.27 NandAESIV4

This register is used to store the fourth word of the 128-bit AES initialization vector.

[Table 2–33](#) gives a description of this register.

**Table 33. NandAESIV4 register description**

Bit	Symbol	Access	Reset	Description
31:0	AES iv 4	R	0x0	Fourth word of AES 128-bit initial value 128-bit vector

## 5.28 NandAESState

This register is used to check the status of the AES description. [Table 2–34](#) gives a description of this register.

**Table 34. NandAESState register description**

Bit	Symbol	Access	Reset	Description
31:2	-	-	-	Reserved
1	AES accept in	R	0x0	“00” Busy: This state represents the busy condition. Only one state machine can be busy at any one time, so when either is busy, neither will accept new data.
0	AES accept key	R	0x1	“01” Key Setup: This is the condition of the module after reset and represents the fact that the AES module will not accept new data until a key has been expanded. This state is also reached briefly (1 clock cycle) during data decryption, indicating that the block can accept a new key for expansion (all round keys have been used) but cannot accept new data (data is still in the final round). “10” Reserved “11” Idle: The AES Module is idle and is able to accept either a new key for expansion or more data for processing.

## 5.29 NandECCErrStatus

This register is used to report error statistics of code words in 8 bit ECC mode. If at least one correctable error is detected in 8 bit ECC mode, the “RAMx decoded with one error” bit from register NandIRQ\_STATUS1 is set. If this bit is set, the ARM can read out the NandECCErrStatus register to know exactly how many errors were detected. The register is updated whenever a codeword with more than one correctable error is detected.

**Table 35. NandECCErrStatus register description (NandECCErrStatus, address 0x1700 0878)**

Bit	Symbol	Access	Reset	Description
31:8	-	-	-	Reserved
7:4	N_ERR_1	R	0000	Number of errors in RAM1
3:0	N_ERR_0	R	0000	Number of errors in RAM0

### 5.30 AES\_FROM\_AHB

The register is used to enable access to the AES engine from AHB. The "AES\_from\_AHB mode" bit enables or disables the possibility to use the AES decryption engine by another AHB master than the NAND flash controller only. When this bit is enabled, AES encrypted content can be written into the SRAMs. After that, the decryption is started by writing to bits DecryptRAM0/1 (bits 1 or 0). The decrypted content can be read when the "Ram1 AES done" or "Ram0 AES done" bits are set in the interrupt status register (see [Table 2-7](#)).

Please note that normal NAND flash operation and AES from AHB operation are mutually exclusive.

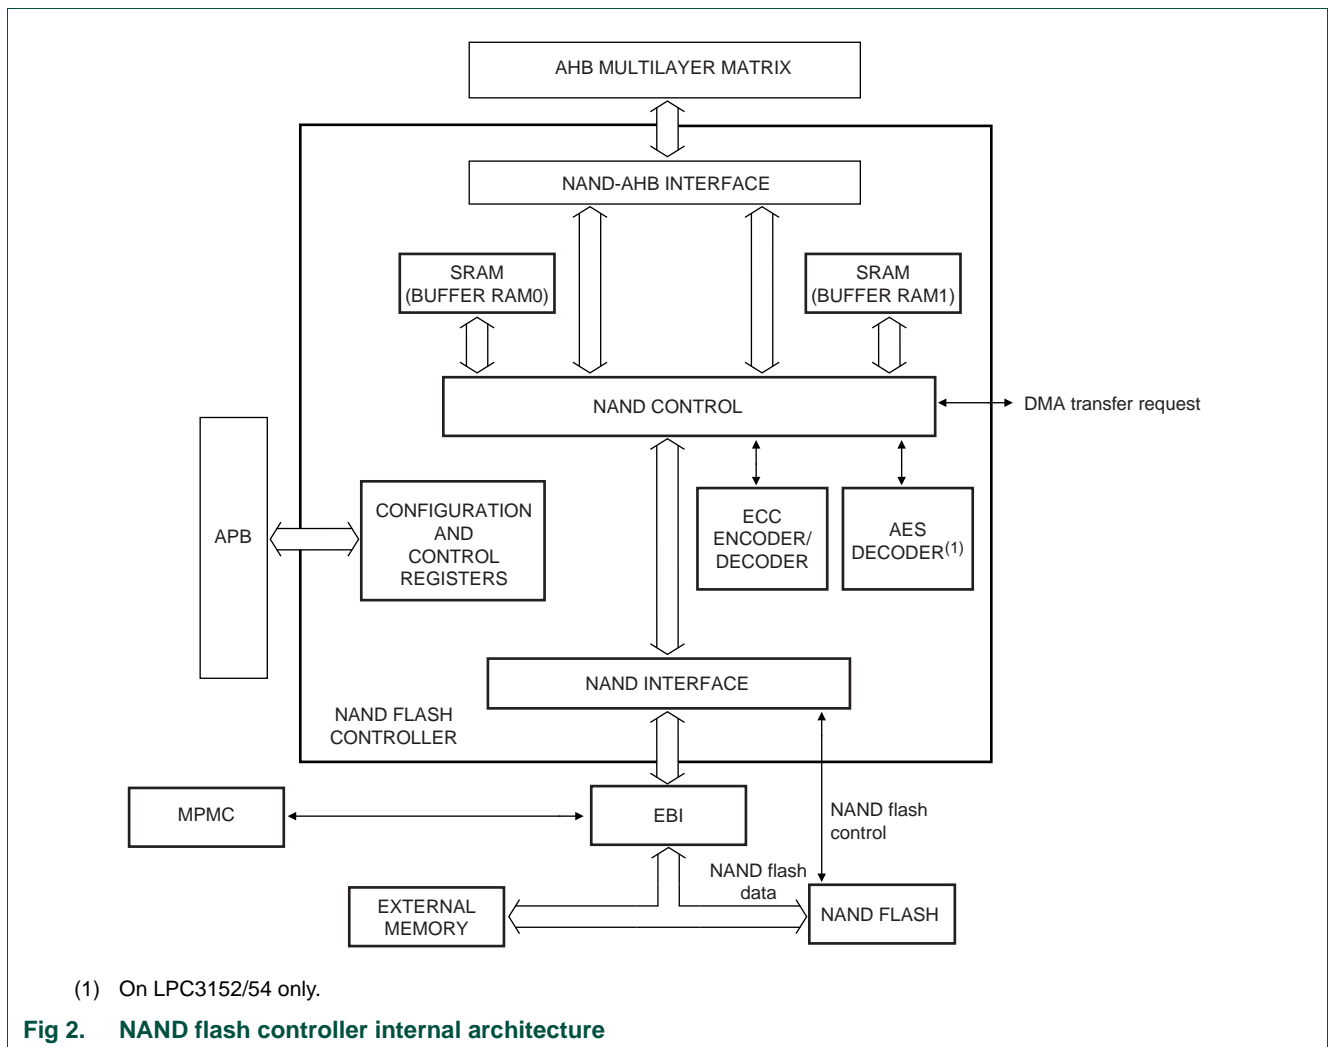

**Table 36. AES\_FROM\_AHB register description (AES\_FROM\_AHB, address 0x1700 087C)**

Bit	Symbol	Access	Reset	Description
7	mode	R/W	0	Set AES from AHB mode 0: AES engine is used by the NAND flash controller. 1: AES engine is used by other AHB bus masters.
6:2	-	-	-	Reserved
1	decryptRAM1	W	0	Decrypt RAM1. When this bit is set to 1, AES decryption of 512 bytes written to the NAND_RAM1 buffer is started.
0	decryptRAM0	W	0	Decrypt RAM0. When this bit is set to 1, AES decryption of 512 bytes written to the NAND_RAM0 buffer is started.

## 6. Functional description

In [Figure 2-2](#) the architecture of the NAND flash controller is displayed. The access to the AHB bus is done via the NAND-AHB interface module which resides inside of the NAND flash controller module. Two 528 bytes (132-words x 32-bits) SRAMs which are placed inside of the NAND flash controller module, are connected to the internal NAND controller in parallel and the access to these SRAMs is shared with the control module. All data path modules (codec, error corrector, syndrome generator, parity generator, NAND interface) are controlled by the main control module. The configuration registers are kept in a separate sub-module which is connected to the APB interface. These registers run on the NANDFLASH\_PCLK. In write mode the data is retrieved out of the SRAM by the NAND flash controller and written to the NAND flash device after being protected with parity symbols. In read mode the data is read from the NAND flash device and temporarily stored in one of the SRAMs to have it corrected by the error corrector. When these

operations are done, the data can be randomly accessed from the SRAMs over the AHB bus using zero wait-states AHB access. The AHB bus is only burdened with data transfers for a very limited time. (the time to upload or download the contents from the SRAM using zero wait states). In decode mode, once the command, address and data have been sent, everything is taken over by the NAND flash controller and the AHB bus is free. In encode mode, the command and data are sent and the AHB bus is again freed up until the moment that the data is available in the SRAM.

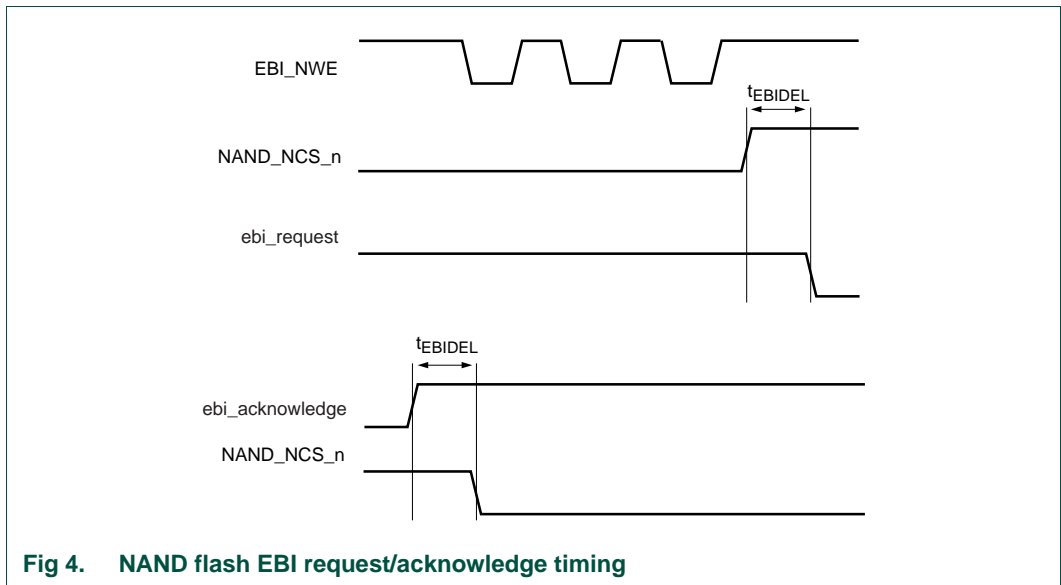

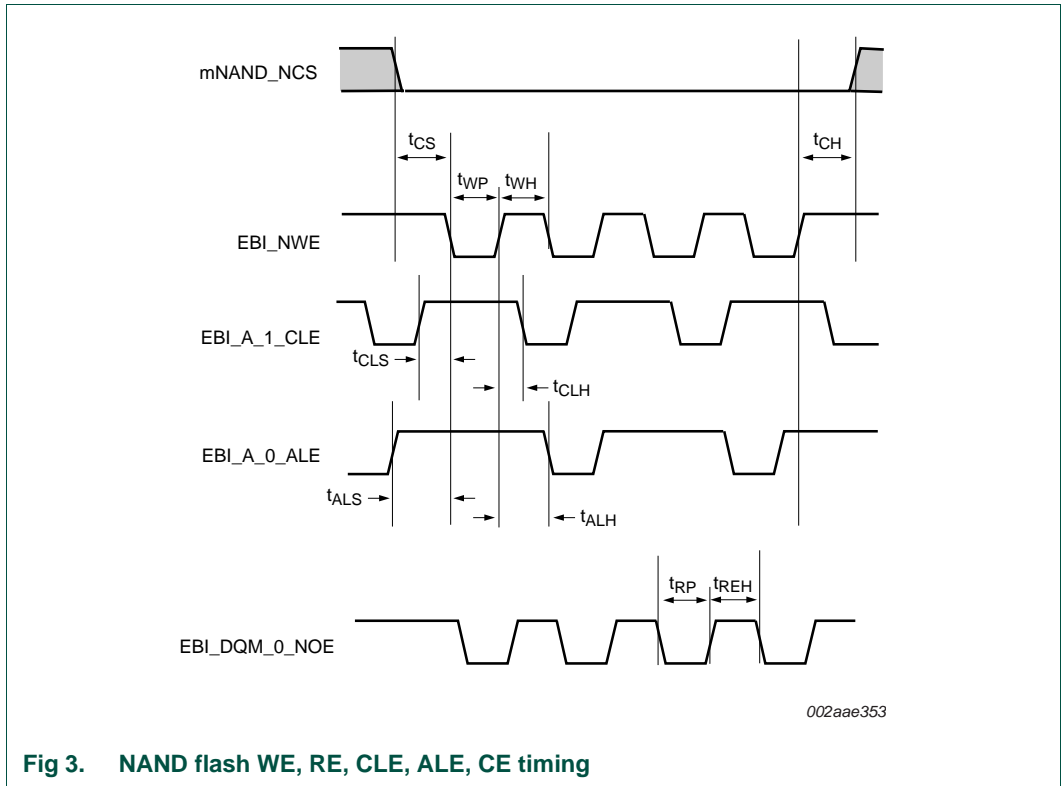

### 6.1 NAND timing diagrams

Table 2-37 shows the timing diagram for the timing parameters in registers NandFlashTiming1 and NandFlashTiming2.

Table 37. NAND flash timing parameters

Symbol	Parameter	Description
$t_{WP}$	$\overline{WE}$ pulse width	This value also covers the $t_{DS}$ , (data setup time) since the data is set up on the I/O line at the same moment as the falling edge of the WE pulse.
$t_{WH}$	$\overline{WE}$ HIGH hold time	The minimum number of clock cycles that the WE pulse is held high before a next falling edge.
$t_{RP}$	$\overline{RE}$ pulse width	The number of clock cycles that the RE pulse is de-asserted.
$t_{REH}$	$\overline{RE}$ HIGH hold time	The minimum number of clock cycles that the RE pulse is held high before a next falling edge.
$t_{CLH}$	CLE hold time	The number of clock cycles that CLE remains asserted after the rising edge of WE.
$t_{CLS}$	CLE set-up time	The number of clock cycles between the rising edge of CLE and the falling edge of WE during a command transfer.
$t_{ALH}$	ALE hold time	The number of clock cycles that ALE remains asserted after the rising edge of WE.
$t_{ALS}$	ALS set-up time	The number of clock cycles between the rising edge of ALE and the falling edge of WE during a command transfer.
$t_{CS}$	$\overline{CE}$ set-up time	The number of clock cycles between the falling edge of CS and the first active signal to the NAND flash.
$t_{CH}$	$\overline{CE}$ hold time	The number of clock cycles between the last active signal to the NAND flash and the rising edge of CS.
$t_{DRD}$	data input delay time	The number of clock cycles between the rising edge of the RE signal and the cycle that the data is clocked in by the controller in case of hardware controlled burst read access.
$t_{SRD}$	single data input delay time	The number of clock cycles between the rising edge of the RE signal and the cycle that the data is clocked in by the controller in case of software controlled single read access.
$t_{EBIDEL}$	EBI delay time	The number of clock cycles between the rising edge of CS and the falling edge of ebireq (request) when backing off from the EBI. OR The number of clock cycles between the rising edge of ebight (grant) and the falling edge of CS when going on the EBI.

## 6.2 Error correction

### 6.2.1 Reed-Solomon code definition

The error correction code used is Reed-Solomon over GF(2<sup>9</sup>). The primitive polynomial g(x) over GF(2) is:

$$g(x) = x^9 + x^4 + 1$$

The code is a Reed-Solomon code of length 469, dimension 459, and minimum distance 11. In each codeword the 10 parity symbols are defined by the remainder polynomial  $R(x)$  to form the code  $RS(469,459,11)$ .

$$R(x) = M(x) \times x^{10} \text{ mod } P(x)$$

where  $M(x)$  is the information and  $P(x)$  the generator polynomial for the RS code:

(1)

$$M(x) = \sum_{j=0}^{458} B_j x^j$$

(2)

$$P(x) = \prod_{k=0}^9 (x + \alpha^k)$$

and  $\alpha$  has the hexadecimal 9-bit representation 0x002.  $\alpha$  is a root of the primitive polynomial  $g(x) = x^9 + x^4 + 1$ .

### 6.2.2 Mapping of the code onto flash pages

A flash page consists of 512 bytes + 16 redundant bytes or a multiple of this. Currently 2048 byte pages + 64 redundant bytes are widely used. The concept is to subdivide every page into groups of 512 information bytes and 16 redundant bytes.

A 2K flash will be subdivided as shown in

Fig 5. Structure from flash page to ECC code words

The 16 redundant bytes are subdivided into:

- 4 bytes free for purposes like wear-leveling, building tables. (an ECC layer can also be applied also over these bytes).
- 12 remaining bytes that consist of 10 parity symbols (90 bits) + 6 dummy bits.

In the end the 459 data words (9 bits per data word) consist of

- 512 data bytes
- 4 extra bytes
- 3 dummy bits at the end

The 10 remaining parity words consist of

- 10 parity symbols
- 3 dummy bits at the end

### 6.2.3 Error correction flow implementation

The error correction flow starting from a codeword  $C(x)$  is shown in [Figure 2–6](#) and follows these steps:

1. Calculate syndromes out of the received codeword.
2. Solve key equation via the Euclidean algorithm.
3. The result of this is the error locator polynomial  $\Lambda(x)$  and the error evaluator polynomial  $\Omega(x)$ .
4. Search for zeros of error locator polynomial using the chien search & Forney algorithm.
5. Evaluate  $\Omega(x)$  at zeros of  $L(x)$ .
6. Send out error locations and values.

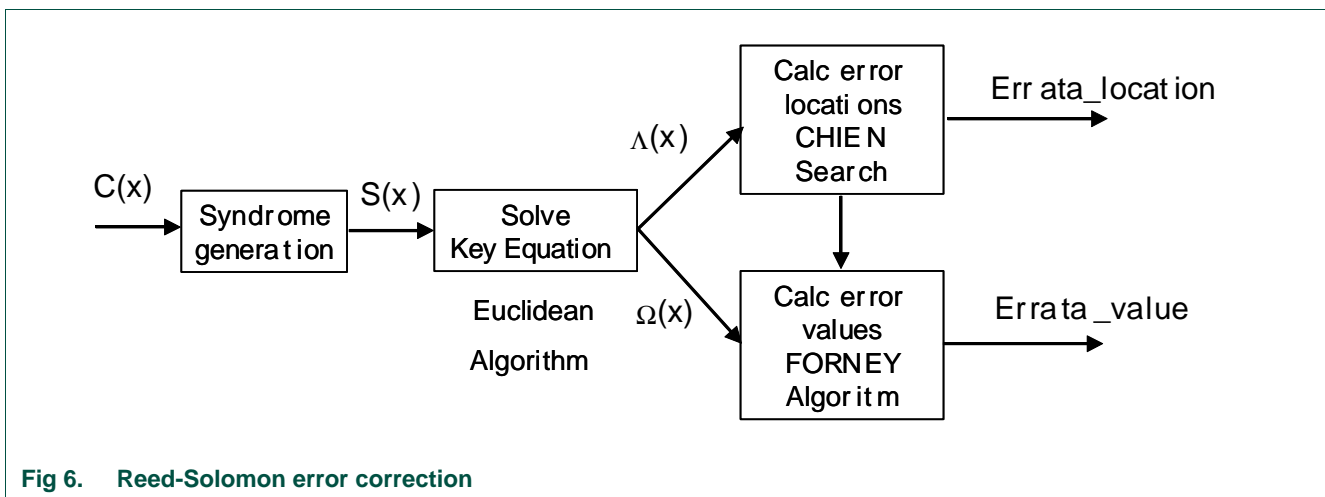

Fig 6. Reed-Solomon error correction

### 6.3 AES decryption

To decrypt the program code with an algorithm like AES, a hardware implementation is needed. To do this without increasing the load on the AHB bus, it is essential that the AES decryption is integrated in the NAND controller module so that ECC and AES can be performed in one go.

In the NAND flash controller, an AES module is connected to the main control module. This module is kicked off after error correction in decode mode. In the read flow, the encrypted data is first read from the flash, error corrected, decrypted in hardware and stored back in the SRAM.

This module needs 11 to 12 clock cycles per 128 bit to process.

Before the module can be used, an AES key and initial value need to be programmed. This is done via four registers, writing four times 32-bit to build the 128-bit values. Upon writing the fourth word the NAND flash controller automatically programs the key/initial value into the AES module. The first register value is the least significant 32 bit field in the 128bit word. The last register value is the most significant 32 bit field in the 128 bit word.

The data is read from the SRAM in chunks of four words, processed in the AES module and sent decrypted back into the SRAM. To pipeline this as much as possible the AES controller reads the next chunk of four words before it is actually needed and stores it in a 128 bit register. In this way the time to decrypt 512 bytes is reduced to around 400 clock cycles.

The data is decrypted in little endian mode. This means that the first byte read from flash is integrated into the AES codeword as least significant byte. The 16th byte read from flash is the most significant byte of the first AES codeword.

### 6.4 EBI operation

To support pin sharing with other memory controllers, NAND flash controller accesses the NAND flash through the EBI module. For every access to the NAND flash, the NAND flash controller will first request access through the EBI before initiating the access. When the access is done, NAND flash withdraws itself from the EBI bus.

Short access can not be interrupted via the ebibackoff signal. These accesses are:

- single byte read
- single byte write
- command write
- address write

A burst data access can be interrupted by the ebibackoff signal. This is done by going off the EBI bus after first deactivating the chip select signal. To be able to use this function the NAND flash needs to be a “CEn don't care” device as the chip select signal to NAND flash will be deactivated before going off the EBI bus. When the EBI bus is free again, chip select is again activated and the burst data access is continued.

Currently, the majority of NAND flash devices support “CEn don't care”. With “CEn don't care”, it is possible to interrupt a sequential read/write by de-asserting CEn high. When CEn is high, the NAND flash device will ignore the values on the NAND flash control

signals. This makes it possible to interrupt a sequential read/write, and pin-share the NAND flash control signals with control signals of other memory controllers. To resume the sequential read/write, CEn is asserted low again.

The NAND flash controller also has an option to disable this CEn deactivation during the EBI back off procedure.

## 7. Power optimization

---

Several mechanisms can be used to save power in the NAND flash controller.

- Internal clock gating is inserted during synthesis
- The presence of variable clock scaling will switch the clocks to a lower frequency
- Software is able to enable or disable every clock to save power when certain parts are not used
  - Software is able to switch clocks in the CGU module, which is the source of the NAND flash controller clocks.

## 8. Programming guide

---

The NAND flash controller can be controlled fully by software, or partly by software and partly by hardware. Both options are described in the next paragraphs.

### 8.1 Software controlled access

The software has basic control over the NAND flash device by accessing registers in the NAND flash controller over the APB bus. The NAND flash controller will then make sure that the IO signals react in the corresponding way. This is implemented in the form of a number of independent actions. These are summed up in [Table 2–38](#)

**Table 38. NAND flash controller software control**

Command	Resulting action
Write NandSetCmd register for NAND flash controller command.	Hardware pulls CS down CLE up & puts command value on the I/O lines WE down WE up CLE down CE up
Write NandSetAddr register for NAND flash controller address.	Hardware pulls CS down ALE up & puts command value on the I/O lines WE down WE up ALE down CE up
Write NandWriteData register for NAND flash controller write data.	Hardware pulls CS down WE down & puts data on the I/O lines WE up CS up
Read NandReadData register for NAND flash controller read data.	Hardware pulls CS down RE down RE up & clocks in data from I/O lines CS up

## 8.2 Hardware controlled access

In this mode the hardware directly performs read and write operations using RE<sub>n</sub>/WE<sub>n</sub> pulses to the NAND flash device. The ARM processor makes sure that the necessary commands and addresses are supplied to the NAND flash device. To do this it programs registers over the APB bus in the NAND flash controller. A read or write burst access is initiated by the NAND flash controller after receiving a command from the CPU. The NAND flash controller will always read data in chunks of 528 bytes per read page command regardless of the fact that the error corrector is turned on or off. For writing the same is valid.

## 8.3 Writing small page NAND flash devices

The following steps are performed when writing a page into a NAND flash device with 512byte large pages. [Figure 2–7](#) illustrates this flow.

1. ARM or DMA writes the 512 or 516 bytes of target data into the SRAM. This triggers the ECC to start generating parity symbols. The RS encoding action is automatically started when the controller detects that byte 512 or byte 516 (can be configured inside the NAND flash controller) is written to one of the SRAMs.

2. ARM sends the data<sup>1</sup> for the CE,CLE and ALE sequences to the NAND flash controller.
3. ARM sends write\_page command, via register NandControlFlow. This will trigger the NAND flash controller to write the contents of the SRAM to the NAND flash device as soon as possible (after filling in the parity bytes).
4. When done the NAND flash controller triggers an interrupt.
5. ARM writes secondary write command to command register.
6. NAND flash controller polls the busy signal, when it goes high an interrupt is triggered.
7. ARM can read the status information via command register and an RE pulse.

Note 1: This is writing the command and address values to the registers in the NAND flash controller, this automatically initiates proper CLE/ALE sequence to the NAND flash device.

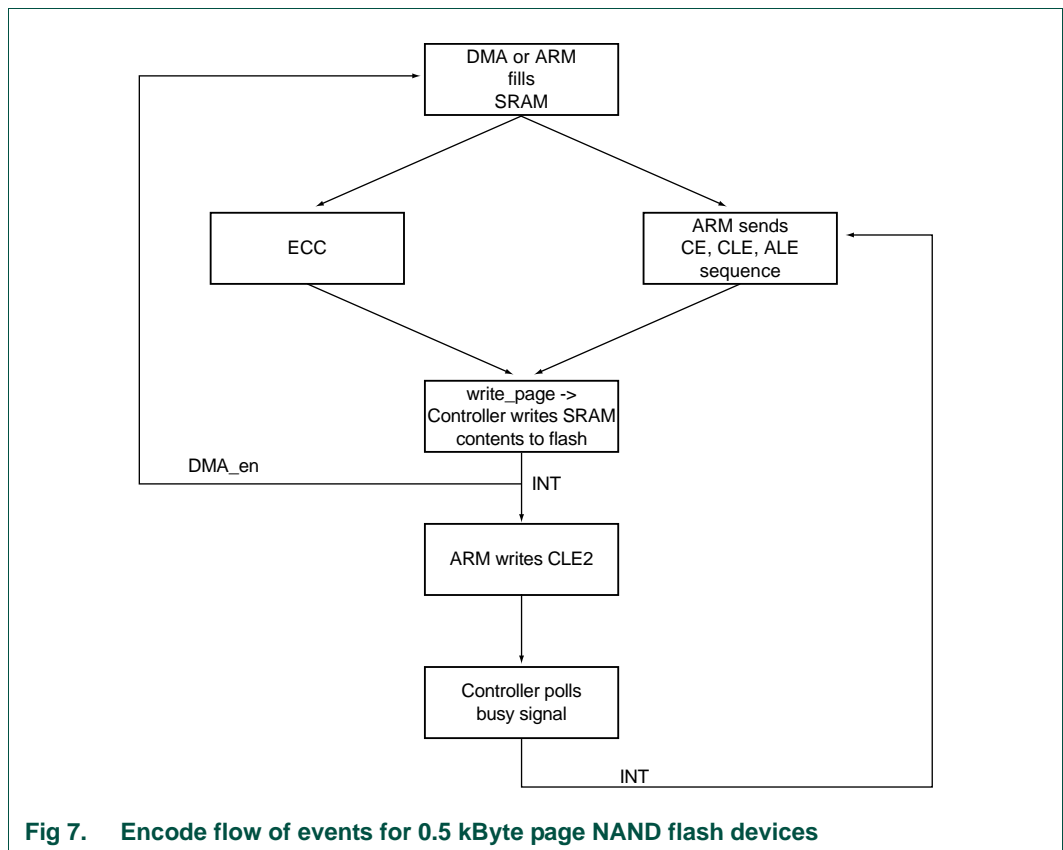

Fig 7. Encode flow of events for 0.5 kByte page NAND flash devices

### 8.3.1 Writing large page NAND flash devices

In the case of a NAND flash device with pages larger than 0.5kB (2kB for example), the ARM only needs to send new commands and addresses every fourth time.

1. This is writing the command and address values to the registers in the NAND flash controller, this automatically initiates proper CLE/ALE sequence to the NAND flash device.

### 8.3.2 Read small page NAND flash devices

The following steps are performed when reading a 528 byte group from the NAND flash device.

1. ARM sends the sequence and data<sup>[1]</sup> for the CE,CLE and ALE pulses
2. When the NAND flash device is ready the NAND flash controller starts reading the data from the NAND flash device using RE pulses
3. When the SRAM has been filled, the error correction is started up on the code word automatically. At the same time, the NAND flash controller triggers an interrupt to let the ARM know that it can start a new read operation
4. After ECC operations have finished, the previous decoded data can be read from the SRAM.

Note 1: This is writing the command and address values to the registers in the NAND flash controller, this automatically initiates proper CLE/ALE sequence to the NAND flash device.

### 8.3.3 Read large page NAND flash devices

As explained earlier for encode mode the ARM only needs to send new commands and addresses every fourth time in the case of a NAND flash device with 2kB large pages.

## 1. Introduction

---

The multi-port memory controller supports the interface to a large number of memory types, such as SDRAM, Low-power (LP) SDRAM, flash, Synchronous Micron flash and ROM.

### 1.1 Feature list

- AMBA 32-bit AHB compliancy.
- Dynamic-memory interface support including SDRAM, JEDEC low-power SDRAM and Micron SyncFlash.
- Asynchronous static memory device support, including RAM, ROM and flash with or without asynchronous page mode.
- Low transaction latency.
- Read and write buffers to reduce latency and to improve performance, particularly for un-cached processors.
- Two AHB-interfaces:
  - one interface for accessing external memory.
  - one separate control interface to program the MPMC. This enables the MPMC registers to be situated in memory with other system peripheral registers.
- 8-bit and 16-bit wide static memory support.
- 16-bit wide chip select SDRAM memory support.
- 16-bit wide chip select Micron SyncFlash memory support.
- Static memory features include:
  - Asynchronous page mode read
  - Programmable wait states
  - Bus turnaround delay
  - Output enable and write enable delays
  - Extended wait
- One chip select for synchronous memory devices and two chip selects for static memory devices.
- Software controllable HCLK to MPMCCLKOUT ratio.
- Power-saving modes control dynamically SDRAM clock enable EBI\_CKE (pin mLCD\_E\_RD) and EBI\_CLKOUT (pin mLCD\_DB\_0).
- Dynamic-memory self-refresh mode supported by either a Power Management Unit (PMU) interface or by software.
- Controller supports 2K, 4K and 8K row address synchronous-memory parts. That is typical 512 Mbit, 256 Mbit, 128 Mbit and 16 Mbit parts, with either 8 DQ bits or 16 DQ bits per device.

- Two reset domains enable dynamic-memory contents to be preserved over a soft reset.
- Locked AHB-transactions supported.
- Support for all AHB burst types.
- Little-endian and big-endian support.
- Support for the External Bus Interface (EBI) that enables the memory controller pads to be shared.

## 2. General description

---

### 2.1 Interface diagram

[Figure 3–8](#) shows the interface diagram of the MPMC module with all connected modules in this IC. The bus-width on the pads reflects the number of bits that are used in this IC. This is because only 16 address and data lines are used. In addition, only one dynamic device and two static devices are supported.

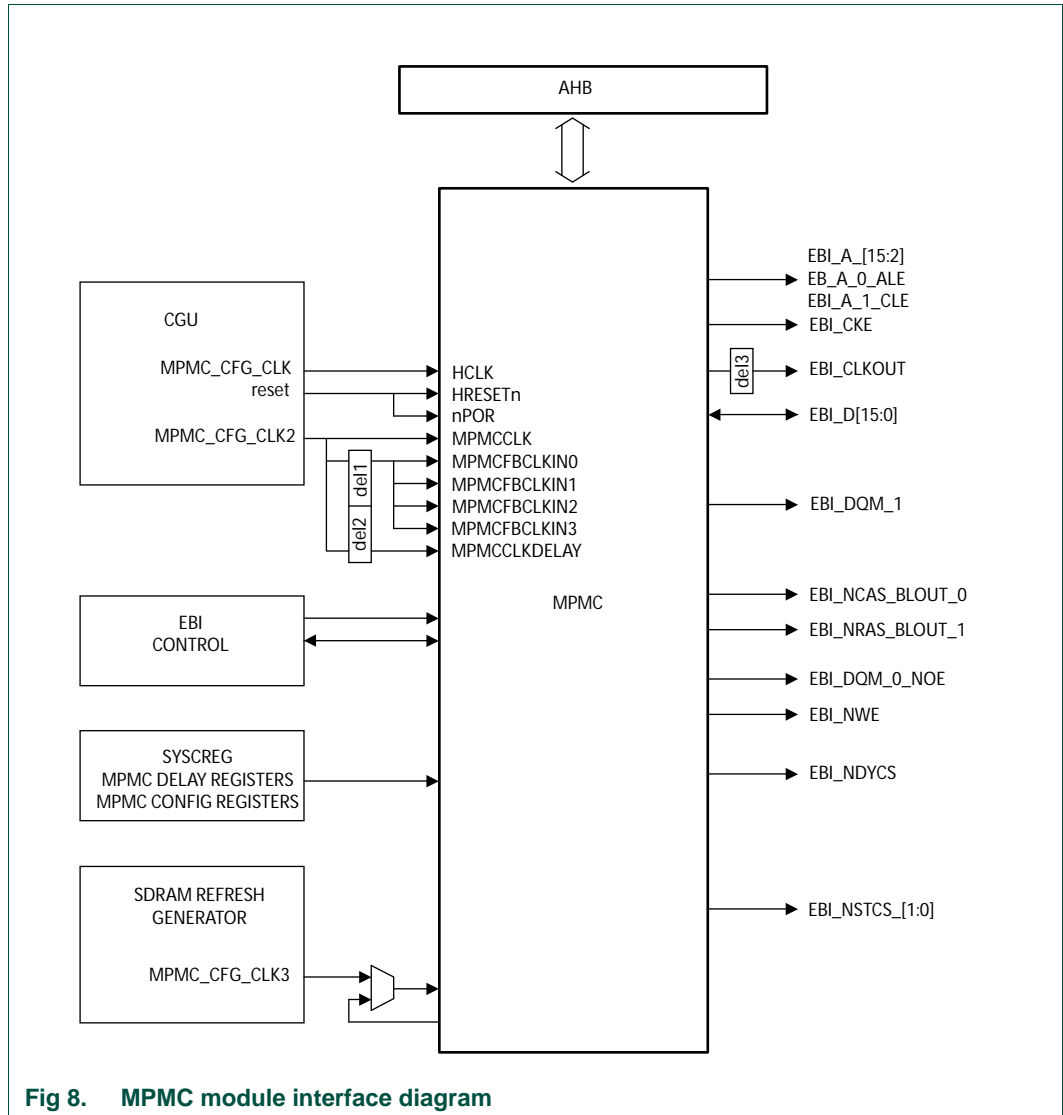

Fig 8. MPMC module interface diagram

## 2.2 Interface description

### 2.2.1 Clock signals

Table 3–39 shows an overview of all clocks that are connected to the MPMC module.

Table 39. MPMC module clock overview

Internal MPMC Clock Name	Clock name	I/O	Source / Destination	Description
HCLK	MPMC_CFG_CLK	I	CGU	Main AHB bus clock
MPMCCLK	MPMC_CFG_CLK_2	I	CGU	Clock for timing all external memory transfers. Should be synchronous to HCLK, where MPMCCLK can be twice the frequency of HCLK
MPMCCLKOUT	EBI_CLKOUT	O	MPMC	Clock towards SDRAM devices. Follows MPMCCLK

Table 39. MPMC module clock overview

Internal MPMC Clock Name	Clock name	I/O	Source / Destination	Description
CLK	MPMC_CFG_CLK3	I	CGU	clock used to generate the refresh pulses towards SDRAM - not influenced by variable clock scaling.
<b>Feedback clocks to re-synchronize SDRAM read data from the off-chip to on-chip domains.</b>				
MPMCFBCLKIN0	Delayed clock from MPMC_CFG_CLK_2	I	CGU	Feedback clock 0
MPMCFBCLKIN1	(see <a href="#">Section 27-4.6.2</a> )	I	CGU	Feedback clock 1
MPMCFBCLKIN2		I	CGU	Feedback clock 2
MPMCFBCLKIN3		I	CGU	Feedback clock 3
MPMCCLKDELAY		I	CGU	Delayed version of MPMCCLK, used in command delayed mode

Several clocks are connected to the MPMC module. [Figure 3-9](#) gives an overview of all connections.

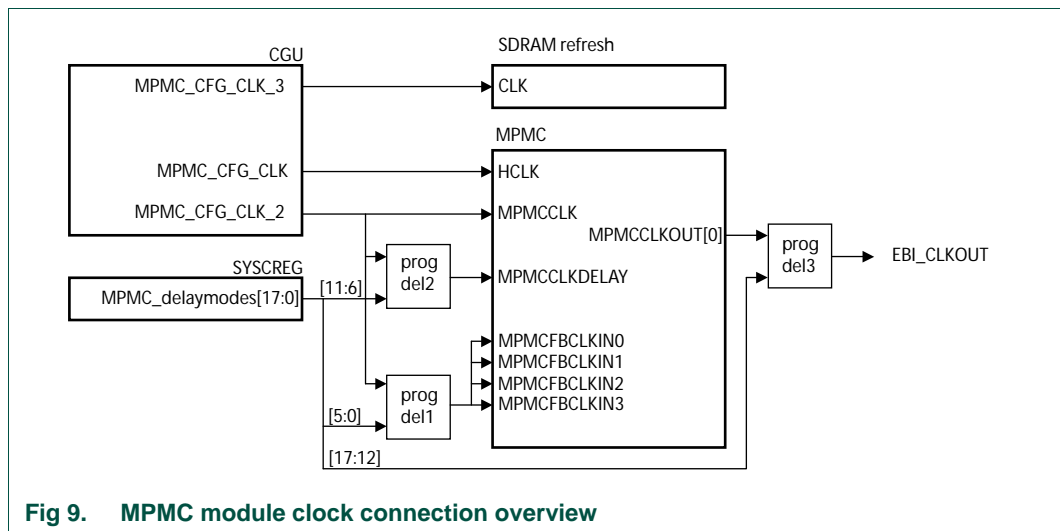

Fig 9. MPMC module clock connection overview

In total 3 delay lines are available, which are described below:

- MPMCCLKDELAY: The amount of delay for MPMCCLKDELAY w.r.t. HCLK (see prog\_del2 block in [Figure 3-9](#)) can be programmed with register MPMC\_delaymodes bits [11:6]. All outgoing signals (data, address and commands) will be delayed with respect to MPMCCLKOUT
- MPMCCLKOUT: The amount of delay for MPMCCLKOUT w.r.t. MPMCCLK (see prog\_del3 block in [Figure 3-9](#)) can be programmed with register MPMC\_delaymodes bits [17:12]. MPMC\_CLKOUT/EBI\_CLKOUT can get an extra delay w.r.t. outgoing data, address and commands
- MPMCFBCLKIN3..0: The amount of delay for MPMCFBCLKIN3..0, w.r.t. MPMCCLK (see prog\_del1 block in [Figure 3-9](#)) can be programmed with register MPMC\_delaymodes bits [5:0]. This delay is used to fine-tune the register moment of data that is read from external memory.

Register MPMC\_delaymodes[17:0] resides in the SYSCREG module (see [Table 27-556](#)).

The MPMC\_CFG\_CLK\_3 is a clock that is not influenced by variable clock scaling and used to generate the refresh pulses towards SDRAM.

## 2.2.2 Reset signals

[Table 3–40](#) shows an overview of all resets that are connected to the MPMC module.

**Table 40. MPMC module reset overview**

Name	Type	Description
HRESETn	I	Active low reset for this module
nPOR	I	Active low power on reset for this module

## 2.2.3 External pin connections

[Table 3–41](#) shows all external pin connection signals towards and from the MPMC module.

**Table 41. MPMC module external signals**

MPMC module name	Pin name/function	Interface	Type	Description
MPMCADDR[15:0]	mLCD_DB_[15:2]/ EBI_A_[15:2] <a href="#">[1]</a> and EBI_A_O_ALE, EBI_A_1_CLE	EBI	O	Address output. Used for both static and SDRAM devices.
MPMCCKEOUT0	mLCD_E_RD/ EBI_CKE <a href="#">[1]</a>	EBI	O	SDRAM clock enables. Used for SDRAM devices.
MPMCCLKOUT0	mLCD_DB_0/ EBI_CLKOUT <a href="#">[1]</a>	EBI	O	SDRAM clocks. Used for SDRAM devices.
MPMCDATAIN[15:0]	EBI_D[15:0]	EBI	I	Read data from memory. Used for both static memory and dynamic memory devices.
MPMCDATAOUT[15:0]	EBI_D[15:0]	EBI	O	Data output to memory. Used for both static memory and dynamic memory devices.
MPMCDQMOUT1	mLCD_RW_WR/ EBI_DQM_1 <a href="#">[1]</a>	EBI	O	Data mask output to SDRAMs. Used for SDRAM devices.
MPMCDQMOUT0 <a href="#">[2]</a> / nMPMCOEOUT <a href="#">[3]</a>	EBI_DQM_0_NOE	EBI	O	For static memory devices this is data mask output (MPMCOEOUT). And for SDRAM devices this is MPMCDQMOUT[0].
nMPMCBLSOUT0/ nMPMCCASOUT	EBI_NCAS_BLOUT_0	EBI	O	Byte lane 0 select (active low) for Static memories (nMPMCBLSOUT0). Same signal acts as column strobe for SDRAM devices (nMPMCCASOUT)
nMPMCBLSOUT1/ nMPMCRASOUT	EBI_NRAS_BLOUT_1	EBI	O	Byte lane 1 select (active low) for Static memories (nMPMCBLSOUT1). Same signal acts as row strobe for SDRAM devices (nMPMCRASOUT).
nMPMCDYCSOUT0	mLCD_RS/EBI_NDYCS <a href="#">[1]</a>	EBI	O	SDRAM chip selects. Used for SDRAM devices.
nMPMCSTSCOUT[1:0]	mLCD_CSB/EBI_NSTCS_0 <a href="#">[1]</a> and mLCD_DB_1/ EBI_NSTCS_1 <a href="#">[1]</a>	EBI	O	Static memory chip selects. Default active low. Used for static memory devices.
nMPMCWEOUT	EBI_NWE	EBI	O	Write enable. Used for SDRAM and static memories.

- [1] The EBI address and control pins are multiplexed with the LCD data and control pins (see [Section 27-4.8](#)).
- [2] For SDRAM devices.
- [3] For static memory devices.

## 2.3 Functional description

The multi-port memory controller block optimizes and controls external memory transactions. The functions of the MPMC blocks are described in this chapter.

### 2.3.1 AHB slave register interface

The AHB slave register interface block enables the registers of the MPMC to be programmed. This module also contains most of the registers and performs the majority of the register address decoding.

### 2.3.2 Memory transaction endianness and transfer width towards registers

To eliminate the possibility of endianness problems, all data transfers to and from the registers of the MPMC must be 32-bits wide. When an access is attempted with a size other than a word (32-bits), it causes an ERROR response on HRESP and the transfer is terminated.

### 2.3.3 AHB slave memory interfaces

The AHB slave memory interfaces enable devices to access the external memories. The memory interfaces are prioritized, with interface 0 having the highest priority. Having more than one memory interface enables high-bandwidth peripherals direct access to the MPMC, without data having to pass over the main system bus. All AHB burst types are supported, enabling the most efficient use of memory bandwidth. The AHB interfaces do not generate SPLIT and RETRY responses.

### 2.3.4 Memory transaction endianness

The endianness of the data transfers to and from the external memories are determined by the Endian mode (N) bit in the MPMCConfig register. The memory controller must be idle (see the busy field of the MPMCStatus register) before endianness is changed, so that the data is transferred correctly.

### 2.3.5 Memory transaction size

Memory transactions can be 8-bits, 16-bits or 32-bits wide. Any access attempted with a size greater than a word (32-bits) causes an ERROR response on HRESP and the transfer is terminated.

### 2.3.6 Write protected memory areas

Write transactions to write-protected memory areas generate an ERROR response on HRESP and the transfer is terminated.

### 2.3.7 Arbiter

The arbiter arbitrates between the AHB slave memory interfaces. AHB interface 0 has the highest access priority and AHB interface 3 has the lowest priority.

### 2.3.8 Data buffers

The AHB interfaces use read and write buffers to improve memory bandwidth and reduce transaction latency. The MPMC contains four 16-word buffers. The buffers are not tied to a particular AHB interface and can be used as read buffers, write buffers or a combination of both. The buffers are allocated automatically. Because of the way the buffers are designed they are always coherent for reads and writes and across AHB memory interfaces. The buffers are enabled on a memory bank basis, using the MPMCDynamicConfig or the MPMCStaticConfig registers.

Write buffers are used to:

- Merge write transactions so that the number of external transactions are minimized.
- Buffer data until the MPMC can complete the write transaction improving AHB write latency.
- Convert all dynamic memory write transactions into quad word bursts on the external memory interface. This enhances transfer efficiency for dynamic memory.
- Reduce external memory traffic. This improves memory bandwidth and reduces power consumption.

Write buffer operation:

- When the buffers are enabled, an AHB write operation writes into the Least Recently Used (LRU) buffer when empty.
- When the LRU buffer is not empty the contents of the buffer are flushed to memory to make space for the AHB write data.
- When a buffer contains write data it is marked as dirty and its contents are written to memory before the buffer can be reallocated.

The write buffers are flushed whenever:

- The memory controller state machine is not busy performing accesses to external memory.
- The memory controller state machine is not busy performing accesses to external memory and a AHB interface is writing to a different buffer.

The smallest buffer flush is a quad word of data.

Read buffers are used to:

- Buffer read requests from memory. Future read requests that hit the buffer read the data from the buffer rather than memory reduce transaction latency.
- Convert all read transactions into quad word bursts on the external memory interface. This enhances transfer efficiency for dynamic memory.
- Reduce external memory traffic. This improves memory bandwidth and reduces power consumption.

Read buffer operation:

- When the buffers are enabled and the read data is contained in one of the buffers the read data is provided directly from the buffer.

- When the read data is not contained in a buffer, the LRU buffer is selected. When the buffer is dirty (contains write data), the write data is flushed to memory. When an empty buffer is available the read command is posted to the memory. While the memory controller is waiting for the data to be returned the memory controller can re-arbitrate to enable additional memory transactions to be processed. When the first data item is returned from memory the read data is provided to the respective AHB port. Other AHB ports can access the data in the buffer when the read transaction has completed.

A buffer filled by performing a read from memory is marked as not-dirty (not containing write data) and its contents are not flushed back to the memory controller unless a subsequent AHB transfer performs a write that hits the buffer.

### 2.3.9 Memory controller state machine

The memory controller state machine comprises two functional blocks:

- A static memory controller
- A dynamic-memory controller

The memory controller state machine holds up to two requests in its internal buffer. It prioritizes and rearranges accesses to maximize memory bandwidth and minimize transaction latency. For example, when AHB interfaces 1 and 0 simultaneously request a data transfer from dynamic memory to different memory banks, and the port 0 request address is to a closed page, but port 1 address is for an already open page, the following sequence occurs:

- The ACT command is sent to open the SDRAM row specified by the AHB interface 0 address.
- The AHB interface 1 access is completed.
- The AHB interface 0 access is completed.

The access priority is modified to take into account the ease of getting data to complete each transfer, but the access priority is always biased to the highest priority AHB interface.

### 2.3.10 Pad interface

The pad interface block provides the interface to the pads. The pad interface uses feedback clocks, MPMCFBCLKIN[3:0], to re synchronize SDRAM read data from the off-chip to on-chip domains.

## 3. Register overview

The registers shown in [Table 3-42](#) are part of the MPMC module. Each register is accessible via the AHB register interface. Note that some configuration registers reside in the SYSCREG module (see [Section 27-4.6.1](#)).

Table 42. Register overview: MPMC module (register base address: 0x1700 8000)

Name	R/W	Address Offset	Description
MPMCControl	R/W	0x000	Control Register
MPMCStatus	R	0x004	Status Register
MPMCConfig	R/W	0x008	Configuration register
MPMCDynamicControl	R/W	0x020	Dynamic Memory Control Register
MPMCDynamicRefresh	R/W	0x024	Dynamic Memory Refresh Timer Register
MPMCDynamicReadConfig	R/W	0x028	Dynamic Memory Read Configuration Register
MPMCDynamicRP	R/W	0x030	Dynamic Memory Precharge Command Period Register
MPMCDynamicRAS	R/W	0x034	Dynamic Memory Active To Precharge Command Period Register
MPMCDynamicSREX	R/W	0x038	Dynamic Memory Self-refresh Exit Time Register
MPMCDynamicAPR	R/W	0x03C	Dynamic Memory Last Data Out To Active Time Register
MPMCDynamicDAL	R/W	0x040	Dynamic Memory Data-in To Active Command Time Register
MPMCDynamicWR	R/W	0x044	Dynamic Memory Write Recovery Time Register
MPMCDynamicRC	R/W	0x048	Dynamic Memory Active To Active Command Period Register
MPMCDynamicRFC	R/W	0x04C	Dynamic Memory Auto-refresh Period Register
MPMCDynamicXSR	R/W	0x050	Dynamic Memory Exit Self-refresh Register
MPMCDynamicRRD	R/W	0x054	Dynamic Memory Active Bank A to Active Bank B Time Register
MPMCDynamicMRD	R/W	0x058	Dynamic Memory Load Mode Register To Active Command Time Register
MPMCStaticExtendedWait	R/W	0x080	Static Memory Extended Wait Register
MPMCDynamicConfig0	R/W	0x100	Dynamic Memory Configuration Registers 0
MPMCDynamicRasCas0	R/W	0x104	Dynamic Memory RAS and CAS Delay Registers 0
-	R/W	0x120 - 0x164	reserved

MPMCStaticConfig1	R/W	0x220	Static Memory Configuration Registers 1
MPMCStaticWaitWen1	R/W	0x224	Static Memory Write Enable Delay Registers 1
MPMCStaticWaitOen1	R/W	0x228	Static Memory Output Enable Delay Registers 1
MPMCStaticWaitRd1	R/W	0x22C	Static Memory Read Delay Registers 1
MPMCStaticWaitPage1	R/W	0x230	Static Memory Page Mode Read Delay Registers 1

**Table 42. Register overview: MPMC module (register base address: 0x1700 8000) ...continued**

Name	R/W	Address Offset	Description
MPMCStaticWaitWr1	R/W	0x234	Static Memory Write Delay Registers 1
MPMCStaticWaitTurn1	R/W	0x238	Static Memory Turn Round Delay Registers 1
-	R/W	0x240 - 0x278	reserved

## 4. Register description

The chapters that follow will give a description for each register that resides in the MPMC module.

### 4.1 MPMC control

The MPMCControl register is a 3-bit, read/write register that controls the memory controller operation. The control bits can be altered during normal operation. This register can be accessed with zero wait states. [Table 3-43](#) gives a description of register MPMCControl.

**Table 43. Description of the register MPMCControl (address 0x1700 8000)**

Bit	Symbol	Access	Reset Value	Description
31:3	-	-	-	Reserved

**Table 43. Description of the register MPMCControl (address 0x1700 8000)**

Bit	Symbol	Access	Reset Value	Description
2	L	R/W	0x0	<p>Indicates normal or low-power mode:</p> <ul style="list-style-type: none"> <li>• 0 = normal mode (reset value on nPOR and HRESETn)</li> <li>• 1 = low-power mode</li> </ul> <p>Entering low-power mode reduces the power consumption of the memory controller. The Dynamic Memory is refreshed as necessary. The memory controller returns to normal functional mode by clearing the low-power mode bit (L), or by AHB or power-on reset. This bit must only be modified when the MPMC is in the idle state. <a href="#">[1]</a></p>
1	M	R/W	0x1	<p>Indicates normal or reset memory map:</p> <ul style="list-style-type: none"> <li>• 0 = normal memory map</li> <li>• 1 = reset memory map.</li> </ul> <p>Static memory chip select 1 is mirrored onto chip select 0 (reset value on nPOR)</p> <p>On power-on reset, chip select 1 is mirrored to both chip select 0 and chip select 1 memory areas. Clearing the M bit enables chip select 0 memory to be accessed.</p>
0	E	R/W	0x1	<p>Indicates when the MPMC is enabled or disabled:</p> <ul style="list-style-type: none"> <li>• 0 = disabled</li> <li>• 1 = enabled (reset value on nPOR and HRESETn)</li> </ul> <p>Disabling the MPMC reduces power consumption. When the memory controller is disabled the memory is not refreshed. The memory controller is enabled by setting the enable bit or by AHB or power-on reset. This bit must only be modified when the MPMC is in the idle state. <a href="#">[1]</a></p>

[1] The external memory cannot be accessed in either the low-power or the disabled state. When a memory access is performed, an error response is generated. The memory-controller AHB-register programming-port can be accessed normally. You can program the MPMC registers in the low-power and/or the disabled state.

## 4.2 MPMCStatus

The 3-bit read-only MPMCStatus register provides MPMC status information. This register can be accessed with zero wait states. [Table 3–44](#) gives a description of register MPMCStatus.

**Table 44. Description of the register MPMCStatus (address 0x1700 8004)**

Bit	Symbol	Access	Reset Value	Description
31:3	-	-	-	Reserved

**Table 44. Description of the register MPMCStatus (address 0x1700 8004) ...continued**

Bit	Symbol	Access	Reset Value	Description
2	SA	R	0x1	This bit indicates the operating mode of the MPMC: 0 = normal mode 1 = self-refresh mode (reset value on nPOR).
1	S	R	0x0	Write buffer status. This bit enables the MPMC to enter cleanly either low-power mode or disabled mode: 0 = write buffers empty (reset value on nPOR) 1 = write buffers contain data.
0	B	R	0x1	This bit ensures that the memory controller enters cleanly either the low-power mode or the disabled mode by determining whether the memory controller is busy or not: 0 = MPMC is idle (reset value on HRESETn) 1 = MPMC is busy performing memory transactions, commands, auto-refresh cycles or is in self-refresh mode (reset value on nPOR and HRESETn).

### 4.3 MPMCConfig

The 2-bit, read/write, MPMCConfig register configures the operation of the memory controller. It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode.

MPMCConfig is accessed with one wait state. [Table 3–45](#) gives a description of register MPMCConfig.

**Table 45. Description of the register MPMCConfig (address 0x1700 8008)**

Bit	Symbol	Access	Reset Value	Description
31:9	-	-	-	Reserved
8	CLK	R/W	0x0	Clock ratio, CLK HCLK:MPMCCLKOUT ratio: 0 = 1:1 (reset value on nPOR) 1 = 1:2
7:1	-	-	-	Reserved
0	N	R/W	0x0	Endian mode, N Endian mode: 0 = little-endian mode 1 = big-endian mode. The MPMCBIGENDIAN signal determines the value of the endian bit on power-on reset, nPOR. Software can override this value. This field is unaffected by the AHB reset, HRESETn. <a href="#">[1]</a>

[1] The value of the MPMCBIGENDIAN signal is reflected in this field. When programmed this register reflects the last value that is written into it. You must flush all data in the MPMC before switching between little-endian mode and big-endian mode.

#### 4.4 MPMCDynamicControl

The 9-bit, read/write, MPMCDynamicControl register is used to control dynamic-memory operation. The control bits can be altered during normal operation. This register can be accessed with zero wait states. [Table 3-46](#) gives a description of register MPMCDynamicControl.

**Table 46. Description of the register MPMCDynamicControl (address 0x1700 8020)**

Bit	Symbol	Access	Reset Value	Description
31:14	-	-	0x0	Reserved
13	DP	R/W	0x0	Low-power SDRAM deep-sleep mode, DP: 0 = normal operation (reset value on nPOR) 1 = enter deep power down mode
12:9	-	-	0x0	Reserved
8:7	I	R/W	0x0	SDRAM initialization, I: 00 = issue SDRAM NORMAL operation command (reset value on nPOR) 01 = issue SDRAM MODE command 10 = issue SDRAM PALL (pre charge all) command 11 = issue SDRAM NOP (no operation) command
6	-	-	0x0	Reserved
5	MMC	R/W	0x0	Memory clock control, MMC: 0 = MPMCCLKOUT enabled (reset value on nPOR) 1 = MPMCCLKOUT disabled <a href="#">[1]</a>
4:3	-	-	0x0	Reserved
2	SR	R/W	0x0	Self-refresh request, MPMCSREFREQ, SR: 0 = normal mode 1 = enter self-refresh mode (reset value on nPOR)  By writing 1 to this bit, self-refresh can be entered under software control. Writing 0 to this bit returns the MPMC to normal mode.  The self-refresh acknowledge bit in the MPMCStatus register must be polled to discover the current operating mode of the MPMC. <a href="#">[2]</a>
1	CS	R/W	0x0	Dynamic-memory clock control, CS: 0 = MPMCCLKOUT stops when all SDRAMs are idle and during self-refresh mode 1 = MPMCCLKOUT runs continuously (reset value on nPOR)  When the clock control is LOW the output clock MPMCCLKOUT is stopped when there are no SDRAM transactions. The clock is also stopped during self-refresh mode.
0	CE	R/W	0x0	Dynamic-memory clock enable, CE: 0 = clock enable of idle devices are deserted to save power (reset value on nPOR) 1 = all clock enables are driven HIGH continuously <a href="#">[3]</a>

- [1] You can disable MPMCCLKOUT when there are no SDRAM memory transactions. When enabled you can use this field in conjunction with the dynamic-memory clock control (CS) field.
- [2] The memory controller exits from the power-on reset with the self-refresh bit on HIGH. To enter normal functional mode, set this bit LOW. Writing to this register with a HIGH places this register into the self-refresh mode. This functionality enables data to be stored over SDRAM self-refresh when the ASIC is powered down.
- [3] Clock enable must be HIGH during SDRAM initialization.

## 4.5 MPMCDynamicRefresh

The 11-bit, read/write, MPMCDynamicRefresh register configures dynamic-memory operation. It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering during either the low-power or the disabled mode. However, these control bits can be altered during normal operation when necessary. This register is accessed with one wait state. [Table 3–47](#) gives a description of register MPMCDynamicRefresh.

**Table 47. Description of the register MPMCDynamicRefresh (address 0x1700 8024)**

Bit	Symbol	Access	Reset Value	Description
31:11	-	-	-	Reserved
10:0	REFRESH	R/W	0x0	Refresh timer, REFRESH: 0x0 = refresh disabled (reset value on nPOR) 0x1 1(x16) = 16 HCLK ticks between SDRAM refresh cycles 0x8 8(x16) = 128 HCLK ticks between SDRAM refresh cycles 0x1-0x7FF n(x16) = 16n HCLK ticks between SDRAM refresh cycles

For example, for the refresh period of 16  $\mu$ s and an HCLK frequency of 50 MHz, the following value must be programmed into this register:

$$16 \times 10^{-6} \times \frac{50 \times 10^6}{16} = 50 = 0x32$$

The refresh cycles are distributed evenly. However, there might be slight variations when the auto-refresh command is issued depending on the status of the memory controller.

Unlike other SDRAM memory timing parameters the refresh period is programmed in the HCLK domain. When variable clock scaling is used, you can program the desired value for the refresh timer in the MPMC\_testmode0 register of the SYSCREG block (see [Table 27–561](#)).

## 4.6 MPMCDynamicReadConfig

The 2-bit, read/write, MPMCDynamicReadConfig register enables you to configure the dynamic-memory read strategy. This register must be modified only during system initialization. This register can be accessed with one wait state. [Table 3–48](#) gives a description of register MPMCDynamicReadConfig.

**Table 48. Description of the register MPMCDynamicReadConfig (address 0x1700 8028)**

Bit	Symbol	Access	Reset Value	Description
31:2	-	-	-	Reserved
1:0	RD	R/W	0x0	Read data strategy, RD: 00 = clock out delayed strategy, using MPMCCLKOUT (command not delayed, clock out delayed). Reset value on nPOR 01 = command delayed strategy, using MPMCCLKDELAY (command delayed, clock out not delayed) 10 = command delayed strategy plus one clock cycle, using MPMCCLKDELAY (command delayed, clock out not delayed) 11 = command delayed strategy plus two clock cycles, using MPMCCLKDELAY (command delayed, clock out not delayed)

## 4.7 MPMCDynamicRP

The 4-bit, read/write, MPMCDynamicRP register enables you to program the pre charge command period,  $t_{RP}$ . This register must be modified only during system initialization. This value is found normally in SDRAM data sheets as  $t_{RP}$ . This register can be accessed with one wait state. [Table 3–49](#) gives a description of register MPMCDynamicRP.

**Table 49. Description of the register MPMCDynamicRP (address 0x1700 8030)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tRP	R/W	0xF	Precharge command period, tRP: 0x0-0xE = n + 1 clock cycles 0xF = 16 clock cycles (reset value on nPOR)

## 4.8 MPMCDynamicRAS

The 4-bit, read/write, MPMCDynamicRAS register enables you to program the active to pre charge command period,  $t_{RAS}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{RAS}$ . This register can be accessed with one wait state. [Table 3–50](#) gives a description of register MPMCDynamicRAS.

**Table 50. Description of the register MPMCDynamicRAS (address 0x1700 8034)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tRAS	R/W	0xF	Active to pre charge command period, tRAS: 0x0-0xE = n + 1 clock cycles 0xF = 16 clock cycles (reset value on nPOR)

## 4.9 MPMCDynamicSREX

The 4-bit, read/write, MPMCDynamicSREX register enables you to program the self-refresh exit time,  $t_{SREX}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{SREX}$ . For devices without this parameter you use the same value as  $t_{XSR}$ . This register can be accessed with one wait state. [Table 3–51](#) gives a description of register MPMCDynamicSREX.

**Table 51. Description of the register MPMCDynamicSREX (address 0x1700 8038)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tSREX	R/W	0xF	Self-refresh exit time, tSREX: 0x0-0xE = n + 1 clock cycles <a href="#">[1]</a> 0xF = 16 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

## 4.10 MPMCDynamicAPR

The 4-bit, read/write, MPMCDynamicAPR register enables you to program the last-data-out to active command time,  $t_{APR}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{APR}$ . This register can be accessed with one wait state. [Table 3–52](#) gives a description of register MPMCDynamicAPR.

**Table 52. Description of the register MPMCDynamicAPR (address 0x1700 803C)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tAPR	R/W	0xF	Last-data-out to active command time, tAPR: 0x0-0xE = n + 1 clock cycles <a href="#">[1]</a> 0xF = 16 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.11 MPMCDynamicDAL

The 4-bit, read/write, MPMCDynamicDAL register enables you to program the data-in to active command time,  $t_{DAL}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{DAL}$  or  $t_{APW}$ . This register can be accessed with one wait state. [Table 3–53](#) gives a description of register MPMCDynamicDAL.

**Table 53. Description of the register MPMCDynamicDAL (address 0x1700 0840)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tDAL	R/W	0xF	Data-in to active command, tDAL: 0x0-0xE = n clock cycles <a href="#">[1]</a> 0xF = 15 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.12 MPMCDynamicWR

The 4-bit, read/write, MPMCDynamicWR register enables you to program the write recovery time,  $t_{WR}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{WR}$ ,  $t_{DPL}$ ,  $t_{RWL}$  or  $t_{RD_L}$ . This register can be accessed with one wait state. [Table 3–54](#) gives a description of register MPMCDynamicWR.

**Table 54. Description of the register MPMCDynamicWR (address 0x1700 8044)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	tWR	R/W	0xF	Write recovery time, tWR: 0x0-0xE = n + 1 clock cycles <a href="#">[1]</a> 0xF = 16 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.13 MPMCDynamicRC

The 5-bit, read/write, MPMCDynamicRC register enables you to program the active to active command period,  $t_{RC}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{RC}$ . This register can be accessed with one wait state. [Table 3–55](#) gives a description of register MPMCDynamicRC.

**Table 55. Description of the register MPMCDynamicRC (address 0x1700 8048)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	tRC	R/W	0x1F	Active to active command period, tRC: 0x0-0x1E = n + 1 clock cycles [1] 0x1F = 32 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.14 MPMCDynamicRFC

The 5-bit, read/write, MPMCDynamicRFC register enables you to program the auto-refresh period and auto-refresh to active command period, t<sub>RFC</sub>. It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering either low-power or disabled mode. This value is found normally in SDRAM data sheets as t<sub>RFC</sub> or sometimes as t<sub>RC</sub>. This register can be accessed with one wait state. [Table 3–56](#) gives a description of register MPMCDynamicRFC.

**Table 56. Description of the register MPMCDynamicRFC (address 0x1700 804C)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	tRFC	R/W	0x1F	Auto-refresh period and auto-refresh to active command period, tRFC: 0x0-0x1E = n + 1 clock cycles [1] 0x1F = 32 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.15 MPMCDynamicXSR

The 5-bit, read/write, MPMCDynamicXSR register enables you to program the exit self-refresh to active command time, t<sub>XSR</sub>. It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. This value is found normally in SDRAM data sheets as t<sub>XSR</sub>. This register can be accessed with one wait state. [Table 3–57](#) gives a description of register MPMCDynamicXSR.

**Table 57. Description of the register MPMCDynamicXSR (address 0x1700 8050)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	tXSR	R/W	0x1F	Exit self-refresh to active command time, tXSR: 0x0-0x1E = n + 1 clock cycles [1] 0x1F = 32 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.16 MPMCDynamicRRD

The 4-bit, read/write, MPMCDynamicRRD register enables you to program the active bank A to active bank B latency,  $t_{RRD}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{RRD}$ . This register can be accessed with one wait state. [Table 3–58](#) gives a description of register MPMCDynamicRRD.

**Table 58. Description of the register MPMCDynamicRRD (address 0x1700 8054)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	$t_{RRD}$	R/W	0xF	Active bank A to active bank B latency, $t_{RRD}$ : 0x0-0xE = $n + 1$ clock cycles <a href="#">[1]</a> 0xF = 16 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.17 MPMCDynamicMRD

The 4-bit, read/write, MPMCDynamicMRD register enables you to program the load mode register to active command time,  $t_{MRD}$ . It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. This value is found normally in SDRAM data sheets as  $t_{MRD}$  or  $t_{RSA}$ . This register can be accessed with one wait state. [Table 3–59](#) gives a description of register MPMCDynamicMRD.

**Table 59. Description of the register MPMCDynamicMRD (0x1700 8058)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	$t_{MRD}$	R/W	0xF	Load mode register to active command time, $t_{MRD}$ : 0x0-0xE = $n + 1$ clock cycles <a href="#">[1]</a> 0xF = 16 clock cycles (reset value on nPOR)

[1] The delay is in MPMCCLK cycles.

#### 4.18 MPMCStaticExtendedWait

The 10-bit, read/write, MPMCStaticExtendedWait register is used to time long static memory read and write transfers (that are longer than can be supported by the MPMCStaticWaitRd[n] or MPMCStaticWaitWr[n] registers) when the EW bit of the MPMCStaticConfig registers is enabled. There is only a single MPMCStaticExtendedWait register. This is used by the relevant static memory chip select when the appropriate ExtendedWait (EW) bit in the MPMCStaticConfig register is set. It is recommended that this register is modified either during system initialization or when there are no current or outstanding transactions. However, when necessary, these control bits can be altered during normal operation. This register can be accessed with one wait state. [Table 3–60](#) gives a description of register MPMCStaticExtendedWait.

**Table 60. Description of the register MPMCStaticExtendedWait (address 0x1700 8080)**

Bit	Symbol	Access	Reset Value	Description
31:10	-	-	-	Reserved
9:0	EXTENDEDWAIT	R/W	0x0	External wait time out, EXTENDEDWAIT: 0x0 = 16 clock cycles <a href="#">[1]</a> (reset value on nPOR) 0x1-0x3FF = (n+1) x16 clock cycles

[1] The delay is in MPMCCLK cycles.

For example, for a static memory read/write transfer time of 16  $\mu$ s and an MPMCCLK frequency of 50 MHz, the following value must be programmed into this register:

$$\left[ 16 \times 10^{-6} \times \left[ \frac{50 \times 10^6}{16} \right] \right] - 1 = 49 = 0x31$$

### 4.19 MPMCDynamicConfig0

The 11-bit, read/write, MPMCDynamicConfig0 registers enable you to program the configuration information for the relevant dynamic-memory chip select. This register is modified normally only during system initialization. These registers can be accessed with one wait state. [Table 3–61](#) gives a description of register MPMCDynamicConfig0.

**Table 61. Description of the register MPMCDynamicConfig0 (address 0x1700 8100)**

Bit	Symbol	Access	Reset Value	Description
31:21	-	-	-	Reserved
20	P	R/W	0x0	Write protect, P: 0 = writes not protected (reset value on nPOR) 1 = write protected.
19	B	R/W	0x0	Buffer enable, B: 0 = buffer disabled for accesses to this chip select (reset value on nPOR) 1 = buffer enabled for accesses to this chip select <a href="#">[1]</a>
18:15	-	-	-	Reserved
14	AM	R/W	0x0	Address mapping, AM. 0 = reset value on nPOR
13	-	-	-	Reserved
12:7	AM	R/W	0x0	Address mapping, AM. 00000000 = reset value on nPOR <a href="#">[2]</a>
6:5	-	-	-	Reserved
4:3	MD	R/W	0x0	Memory device, MD: 00 = SDRAM (reset value on nPOR) 01 = low-power SDRAM 10 = Micron SyncFlash 11 = reserved
2:0	-	-	-	Reserved

[1] The buffers must be disabled during SDRAM and SyncFlash initialization. They must also be disabled when performing SyncFlash commands. The buffers must be enabled during normal operation.

[2] The SDRAM column and row width and number of banks are computed automatically from the address mapping.

Address mappings that are not shown in [Table 3–62](#) are reserved.

**Table 62. Address mapping**

[14]	[12]	[11:9]	[8:7]	Description
16-bit external bus high-performance address mapping (Row, Bank, Column)				
0	0	000	00	16Mb (2Mx8), 2 banks, row length = 11, column length = 9
0	0	000	01	16Mb (1Mx16), 2 banks, row length = 11, column length = 8
0	0	001	00	64Mb (8Mx8), 4 banks, row length = 12, column length = 9
0	0	001	01	64Mb (4Mx16), 4 banks, row length = 12, column length = 8
0	0	010	00	128Mb (16Mx8), 4 banks, row length = 12, column length = 10
0	0	010	01	128Mb (8Mx16), 4 banks, row length = 12, column length = 9
0	0	011	00	256Mb (32Mx8), 4 banks, row length = 13, column length = 10
0	0	011	01	256Mb (16Mx16), 4 banks, row length = 13, column length = 9
0	0	100	00	512Mb (64Mx8), 4 banks, row length = 13, column length = 11

Table 62. Address mapping

[14]	[12]	[11:9]	[8:7]	Description
0	0	100	01	512Mb (32Mx16), 4 banks, row length = 13, column length = 10
16-bit external bus low-power SDRAM address mapping (Bank, Row, Column)				
0	1	000	00	16Mb (2Mx8), 2 banks, row length = 11, column length = 9
0	1	000	01	16Mb (1Mx16), 2 banks, row length = 11, column length = 8
0	1	001	00	64Mb (8Mx8), 2 banks, row length = 12, column length = 9
0	1	001	01	64Mb (4Mx16), 4 banks, row length = 12, column length = 8
0	1	010	00	128Mb (16Mx8), 4 banks, row length = 12, column length = 10
0	1	010	01	128Mb (8Mx16), 4 banks, row length = 12, column length = 9
0	1	011	00	256Mb (32Mx8), 4 banks, row length = 13, column length = 10
0	1	011	01	256Mb (16Mx16), 4 banks, row length = 13, column length = 9
0	1	100	00	512Mb (64Mx8), 4 banks, row length = 13, column length = 11
0	1	100	01	512Mb (32Mx16), 4 banks, row length = 13, column length = 10

The LPC31xx always interface with external SDRAM devices using a 16-bit wide data bus. The SDRAM chip select can be connected to a single 16-bit memory device; in this case x16 mapping values ( MPMCDynamicConfig0[8:7] = 01) should be used. When the SDRAM chip select is connected to two 8-bit memory devices to form a 16-bit external system memory, x8 mapping values ( MPMCDynamicConfig0[8:7] = 00) should be used. For linear AHB address to SDRAM bank mapping the bank select signals (BAx) of the SDRAM device should be connected as shown in the following tables.

**Table 63. 16-bit wide data bus address mapping, SDRAM (RBC)**

<b>16-bit wide device 16M SDRAM (1M × 16, RBC)</b>

### 4.20 MPMCDynamicRasCas0

The 4-bit, read/write, MPMCDynamicRasCas0 registers enable you to program the RAS and CAS latencies for the relevant dynamic memory. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. The MPMCDynamicRasCas0 registers are accessed with one wait state. The values programmed into these registers must be consistent with the values used to initialize the SDRAM memory device. [Table 3–65](#) gives a description of register MPMCDynamicRasCas0.

**Table 65. Description of the register MPMCDynamicRasCas0 (address 0x1700 8104)**

Bit	Symbol	Access	Reset Value	Description
31:10	-	-	-	Reserved
9:8	CAS	R/W	0x3	CAS latency, CAS: 00 = reserved 01 = one clock cycle 10 = two clock cycles 11 = three clock cycles (reset value on nPOR)
7:2	-	-	-	Reserved
1:0	RAS	R/W	0x3	RAS latency (active to read/write delay), RAS: 00 = reserved 01 = one clock cycle <a href="#">[1]</a> 10 = two clock cycles 11 = three clock cycles (reset value on nPOR)

[1] The RAS to CAS latency (RAS) and the CAS latency (CAS) are each defined in MPMCCLK cycles.

### 4.21 MPMCStaticConfig0/1

The 8-bit, read/write, MPMCStaticConfig0/1 registers are used to configure the static memory configuration. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. The MPMCStaticConfig0/1 registers are accessed with one wait state. Synchronous burst mode memory devices are not supported. [Table 3–66](#) gives a description of register MPMCStaticConfig0/1.

**Table 66. Description of the register MPMCStaticConfig (MPMCStaticConfig0, address 0x1700 8200 and MPMCStaticConfig1 0x1700 8220)**

Bit	Symbol	Access	Reset Value	Description
31:2 1	-	-	0x0	reserved
20	WP	R/W	0x0	WP R/W 0x0 Write protect. 0 = writes not protected (reset value on nPOR) 1 = write protected.
19	B	R/W	0x0	Buffer enable. 0 = write buffer disabled (reset value on nPOR) 1 = write buffer enabled.
18:9	-	W	0x0	Read undefined. Write as 0.
8	EW	R/WQ	0x0	Extended wait (EW) uses the MPMCStaticExtendedWait Register to time both the read and write transfers rather than the MPMCStaticWaitRd and MPMCStaticWaitWr Registers. This enables much longer transactions. 0 = Extended wait disabled (reset value on nPOR) 1 = Extended wait enabled.
7	BLS	R/W	0x0	This bit affects the behavior of the EBI_NCAS_BLOUT_0, EBI_NRAS_BLOUT_1 and EBI_nWE signals on the External Memory Interface. When the BLS bit is set to 1, the nBLOUT[1:0] signals are byte lane enable strobes and will be low for both static memory read and write access, and signal EBI_nWE will be low for writes. This is used when interfacing to a static memory with multiple byte lane strobe pins and a separate write strobe pin.  When the BLS bit is set to 0, the nBLOUT[1:0] signals become byte lane write strobes and will only be low during static memory writes. The EBI_nWE signal never goes active when BLS is 0.  Writes: 1 = The active bits in nBLOUT[1:0] are LOW; EBI_nWE is active 0 = The active bits in nBLOUT[1:0] are LOW; EBI_nWE is NOT active  Reads: 1 = The active bits in nBLOUT[1:0] are LOW 0 = All the bits in nBLOUT[1:0] are HIGH
6	PC	R/W	0x0	Chip select polarity, PC: 0 = active LOW chip select 1 = active HIGH chip select The relevant MPMCSTCSxPOL signal determines the value of the chip select polarity on power-on reset, nPOR. Software can override this value. This field is unaffected by AHB reset, HRESETn. <a href="#">[3]</a>
5:4	-	-	-	Reserved

**Table 66. Description of the register MPMCStaticConfig (MPMCStaticConfig0, address 0x1700 8200 and MPMCStaticConfig1 0x1700 8220) ...continued**

Bit	Symbol	Access	Reset Value	Description
3	PM	R/W	0x0	Page mode, PM: 0 = disabled (reset value on nPOR) 1 = Async page mode enabled (page length four) In page mode the MPMC can burst up to four external accesses. Therefore, devices with asynchronous page mode burst four or higher devices are supported. Asynchronous page mode burst two devices are not supported and must be accessed normally.
2	-	-	-	Reserved
1:0	MW	R/W	0x0	Memory width, MW: 00 = 8-bit (reset value for chip select 0, 2 and 3 on nPOR) 01 = 16-bit 10 = reserved 11 = reserved The MPMCSTCS1MW[1:0] signal determines the value of the chip select 1 memory width field on power-on reset, nPOR. Software can override this value. This field is unaffected by AHB reset, HRESETn. <a href="#">[4]</a>

- [1] Extended wait and page mode cannot be selected simultaneously.
- [2] For chip select 1, the value of the MPMCSTCS1PB signal is reflected in this field. When programmed this register reflects the last value that is written into it.
- [3] The value of the relevant MPMCSTCSxPOL signal is reflected in this field. When programmed this register reflects the last value that is written into it.
- [4] For chip select 1, the value of the MPMCSTCS1MW[1:0] signal is reflected in this field. When programmed this register reflects the last value that is written into it. MPMCSTCS1MW[1:0] value can be set in SYSCREG\_WIRE\_EBI\_MSIZE\_INIT (address 0x1300 2874).

## 4.22 MPMCStaticWaitWen0/1

The 4-bit, read/write, MPMCStaticWaitWen0/1 registers enable you to program the delay from the chip select to the write enable. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. The MPMCStaticWaitWen0/1 registers are accessed with one wait state. [Table 3–67](#) gives a description of register MPMCStaticWaitWen0/1.

**Table 67. Description of the register MPMCStaticWaitWen (MPMCStaticWaitWen0, address 0x1700 8204 and MPMCStaticWaitWen1, address 0x1700 8224)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	WAITWEN	R/W	0x0	Wait write enable, WAITWEN Delay from chip select assertion to write enable: 0000 = one HCLK cycle delay between assertion of chip select and write enable (reset value on nPOR) 0001-1111 = (n + 1) HCLK cycle delay <a href="#">[1]</a>

- [1] The delay is (WAITWEN + 1) x tHCLK.

### 4.23 MPMCStaticWaitOen0/1

The 4-bit, read/write, MPMCStaticWaitOen0/1 registers enable you to program the delay from the chip select or address change, whichever is later, to the output enable. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. The MPMCStaticWaitOen0/1 registers are accessed with one wait state. [Table 3–68](#) gives a description of register MPMCStaticWaitOen0/1.

**Table 68.** Description of the register MPMCStaticWaitOen (MPMCStaticWaitOen0, address 0x1700 8208 and MPMCStaticWaitOen1, address 0x1700 8228)

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	WAITOEN	R/W	0x0	Wait output enable, WAITOEN Delay from chip select assertion to output enable: 0000 = No delay (reset value on nPOR) 0001-1111= n cycle delay <a href="#">[1]</a>

[1] The delay is WAITOEN x tHCLK.

### 4.24 MPMCStaticWaitRd0/1

The 5-bit, read/write, MPMCStaticWaitRd0/1 registers enable you to program the delay from the chip select to the read access. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. It is not used when the extended wait bit is enabled in the MPMCStaticConfig0/1 registers. The MPMCStaticWaitRd0/1 registers are accessed with one wait state. [Table 3–69](#) gives a description of register MPMCStaticWaitRd0/1.

**Table 69.** Description of the register MPMCStaticWaitRd (MPMCStaticWaitRd0, address 0x1700 820C and MPMCStaticWaitRd1, address 0x1700 8022C)

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	WAITRD	R/W	0x1F	Non-page mode read wait states or asynchronous page mode read first access wait state, WAITRD Non-page mode read or asynchronous page mode read, first read only: 00000-11110 = (n + 1) HCLK cycles for read accesses <a href="#">[1]</a> 11111 = 32 HCLK cycles for read accesses (reset value on nPOR)

[1] For non-sequential reads, the wait state time is (WAITRD + 1) x tHCLK.

### 4.25 MPMCStaticWaitPage0/1

The 5-bit, read/write, MPMCStaticWaitPage0/1 registers enable you to program the delay for asynchronous page mode sequential accesses. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. MPMCStaticWaitPage0/1 is accessed with one wait state. [Table 3–70](#) gives a description of register MPMCStaticWaitPage0/1.

**Table 70. Description of the register MPMCStaticWaitPage (MPMCStaticWaitPage0, address 0x1700 8210 and MPMCStaticWaitPage1, address 0x1700 8230)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	WAITPAGE	R/W	0x1F	Asynchronous page mode read after the first read wait states, WAITPAGE Number of wait states for asynchronous page mode read accesses after the first read: 00000-11110 = (n+ 1) HCLK cycle read access time [1] 11111 = 32 HCLK cycle read access time (reset value on nPOR)

[1] For asynchronous page mode read for sequential reads, the wait state time for page mode accesses after the first read is (WAITPAGE + 1) x tHCLK.

#### 4.26 MPMCStaticWaitWr0/1

The 5-bit, read/write, MPMCStaticWaitWr0/1 registers enable you to program the delay from the chip select to the write access. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. These registers are not used when the extended wait (EW) bit is enabled in the MPMCStaticConfig register. The MPMCStaticWaitWr0/1 registers are accessed with one wait state. [Table 3–71](#) gives a description of register MPMCStaticWaitWr0/1.

**Table 71. Description of the register MPMCStaticWaitWr (MPMCStaticWaitWr0, address 0x1700 8214 and MPMCStaticWaitWr1, address 0x1700 8234)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved
4:0	WAITWR	R/W	0x1F	Write wait states, WAITWR SRAM wait state time for write accesses after the first read: 00000-11110 = (n + 2) HCLK cycle write access time [1] 11111 = 33 HCLK cycle write access time (reset value on nPOR)

[1] The wait state time for write accesses after the first read is WAITWR (n + 2) x tHCLK.

#### 4.27 MPMCStaticWaitTurn0/1

The 4-bit, read/write, MPMCStaticWaitTurn0/1 registers enable you to program the number of bus turnaround cycles. It is recommended that these registers are modified either during system initialization or when there are no current or outstanding transactions. This can be ensured by waiting until the MPMC is idle and then entering low-power or disabled mode. The MPMCStaticWaitTurn0/1 registers are accessed with one wait state. To prevent bus contention on the external memory data bus, the WAITTURN field controls the number of bus turnaround cycles added between static memory read and write accesses. The WAITTURN field also controls the number of turnaround cycles between static memory and dynamic memory accesses. [Table 3–72](#) gives a description of register MPMCStaticWaitTurn0/1.

**Table 72. Description of the register MPMCStaticWaitTurn (MPMCStaticWaitTurn0, address 0x1700 8218 and MPMCStaticWaitTurn1, address 0x1700 8238)**

Bit	Symbol	Access	Reset Value	Description
31:4	-	-	-	Reserved
3:0	WAITTURN	R/W	0xF	Bus turnaround cycles, WAITTURN: 0000-1110 = (n + 1) HCLK turnaround cycles <a href="#">[1]</a> 1111 = 16 HCLK turnaround cycles (reset value on nPOR)

[1] Bus turnaround time is (WAITTURN + 1) x tHCLK.

## 5. Power optimization

The MPMC is partly low-level clock gated. This feature is built in hardware and software does not have any control over this feature. Low-level clock gating involves grouping a number (in this case 32) of d-type flip-flops together and only enabling a clock to them when required. This is done for reducing power consumption.

## 6. Programming guide

### 6.1 SDRAM initialization

This chapter describes the initialization of both high performance and low performance SDRAM. And describes in more detail the initialization of the Mode Register and/or Extended Mode Register that is part of the initialization of the SDRAM.

### 6.2 Initialization of high performance SDRAM (RBC)

Although the initialization for different kind of SDRAMs is almost the same, it is advised to check the SDRAM data sheet for the start up procedure. For extensive examples consult the *ARM Technical Reference Manual of the MPMC (PI172)*. An example is given below:

1. Disable buffers during SDRAM initialization. Dynamic-memory clock enable (CE) must be HIGH during SDRAM initialization. Enable MPMC and use normal address map in control register.
2. Wait 100ms after the power is applied and the clocks are stable.
3. Set SDRAM Initialization value to NOP in Dynamic Control register, to perform a NOP command to SDRAM.
4. Set SDRAM Initialization value to PALL in Dynamic Control register, to perform a pre-charge all command to SDRAM.
5. Program minimum refresh value (0x1 = 16 HCLKS) in MPMCDynamicRefresh register..
6. Wait until several (Micron recommends minimum of 2 refresh cycles for their SDRAMs) SDRAM refresh cycles have occurred.
7. Program the operational value in the refresh register.
8. Program the operational value in the latency register.
9. Program the operational value in the configuration register.

10. Set SDRAM Initialization value to MODE in Dynamic Control register, to perform a MODE command to SDRAM.
11. Read from SDRAM to program mode register.
12. Set SDRAM Initialization value to NORMAL. Dynamic-memory clock enable (CE) can be made LOW, than idle devices are de-asserted to save power.
13. Enable buffers.

It does not matter what type of SDRAM is used for choosing high performance or low power address mapping. Meaning to say it is possible to use a high performance SDRAM with low power address mapping and the other way around, but it can have an influence on the power dissipation.

#### Example:

```
void sdram_init(void)
{
    pSYSREG_REGS sysregs = (pSYSREG_REGS)SYSREG_BASE;
    pvhMpmcPl172Regs pl172Regs =
        pvhMpmcPl172Regs)AHB_MPMC_PL172_CFG_BASE;
    UInt32 *ptr = NULL;
    int i = 0;
    volatile int j,addr;
    sysregs->mpmp_delaymodes=0x0;
    pl172Regs->MpmcControl = 0x01;
    pl172Regs->MpmcConfig = 0x000;
    pl172Regs->MpmcDyCntl = VH_MPMC_DYCNTRL_REG_POR_VAL;
    // Ensure that the following values have the following value:
    pl172Regs->MpmcDyCntl = 0x7; // Clock enable must be high during SDRAM initialisation
    pl172Regs->MpmcDynamic[SDRAM_SEL].Config = 0x0; // During SDRAM initialisation buffers
    // disabled.
    /* Clock out delay methodology */
    pl172Regs->MpmcDyRdCfg = 0x00;
    /* 0. Clear M-bit in MPMCControl */
    pl172Regs->MpmcControl = 0x01;
    /* 1. Wait 100ms after the power is applied and the clocks are stabilized
    */
    for (i=500;i>0;i--) {}
    /* 2. Set SDRAM Initialization (I) value to NOP. This issues a NOP to the SDRAM */
    pl172Regs->MpmcDyCntl = 0x183; //issue NOP to SDRAM
    /* wait */
    for (i=4;i>0;i--) {}
    /* 3. Set SDRAM Initialization (I) value to PALL (PRE-ALL). This issues a pre charge
    all instruction to the SDRAM */
    pl172Regs->MpmcDyCntl = 0x103; //issue pre charge all instruction to the SDRAM
    memories
    /* Wait for tRP approx */
    for (i=4;i>0;i--) {}
    /* 4. Perform a number of refresh cycles */
    pl172Regs->MpmcDyRef = 0x2;
    /* Wait for tRP approx */
    for (i=4;i>0;i--) {}
}
```

```

/* 5. Wait until two SDRAM refresh cycles have occurred */
for(i=10;i>0;i--) {}
/* 6. Program the operational value in the refresh register.
MpmcDyRef = (tref / #rows) * HCLK / 16.
For tref = 64000 ms, #rows = 4096, HCLK = 16 MHz à MpmcDyRef =11,7 => 0xB */
pll72Regs->MpmcDyRef = 0xB;
/* Wait for tRP approx */
for (i=20;i>0;i--) {}
/* 7. Program the operational value in the latency register. */
pll72Regs->MpmcDynamic[SDRAM_SEL].RasCas = 0x0202;
/* Wait for tRP approx */
for (i=20;i>0;i--) {}
/* 8. Program the operational value in the configuration register. */
pll72Regs->MpmcDynamic[SDRAM_SEL].Config = 0x00280; // RBC address mapping
/* Wait for tRP approx */
for (i=20;i>0;i--) {}
/* 9. Set SDRAM Initialization (I) value to MODE.*/
pll72Regs->MpmcDyCntl = 0x083;
addr = SDRAM0 + 0x11800; /* */
ptr = (UInt32 *) addr;
for (i =0; i < 1; i++) {
/* 10. Read from SDRAM to program mode register. Write 0x22 to add pins 0f SDRAM.*/
j = ptr[i];
// The following 'if' statement doesn't have any functional value. This is done to
avoid that the // statement j = ptr[i] is not compiled away.
if (j!= (i | (1 << 9) | (2 << 18) | (3 << 27))){}
/* Wait some time */
for (i=400;i>0;i--) {}
/* 11. Initialisation of SDRAM to SDRAM NORMAL.*/
pll72Regs->MpmcDyCntl = 0x000; //initialisation to SDRAM NORMAL
/* 12. Buffers are enabled.*/
pll72Regs->MpmcDynamic[SDRAM_SEL].Config = 0x80283; // RBC address mapping
pll72Regs->MpmcControl = 0x01;}

```

### 6.3 Initialization of low power SDRAM (BRC)

The procedure shown in [Section 3–6.2](#) can be used also for the initialization of a low power SDRAM. In that case only the address mapping has to be changed for low power and the address for programming the Mode Register has to be changed.

For a specific low power initialization sequence, you can consult the *ARM Technical Reference Manual of the MPMC*.

### 6.4 Initialization Mode Register or Extended Mode Register of SDRAM

Dependent of the size of the SDRAM, RBC address mapping or BRC address mapping you have to read from different addresses to program the Mode register or Extended Mode Register of the (mobile) SDRAM.

### 6.5 High performance SDRAM (RBC)

Writing 0x23 to the Mode Register implies the following:

- Burst length = 8
- Burst type = Sequential
- CAS latency = 2
- Operating mode = Standard Operation
- Write burst mode = Programmed Burst Length.

Offset mode register settings are given in [Table 3–73](#):

**Table 73. High performance SDRAM address mapping (RBC)**

SDRAM size (Mbit)	Total SDRAM size	Bit places shifted (bit)	Offset mode register address <a href="#">[1]</a>
16 (1Mx16)	2 MB	10	0x08C00
16 (2Mx8)	4 MB	11	0x11800
64 (4Mx16)	8 MB	11	0x11800
64 (8Mx8)	16 MB	12	0x23000
128 (8Mx16)	16 MB	12	0x23000
128 (16Mx8)	32 MB	13	0x46000
256 (16Mx16)	32 MB	12	0x23000
256 (32Mx8)	64 MB	13	0x46000
512 (32Mx16)	64 MB	13	0x46000
512 (64Mx8)	128 MB	14	0x8C000

[1] Base address of the SDRAM is 0x3000 0000 for programming mode register.

Example: Initialization of the mode register of a high performance SDRAM 64 Mbit (4M x 16) with RBC address mapping.

```
#define SDRAM0_BASE 0x30000000
#define SDRAM0 SDRAM0_BASE
int addr;
UInt32 *ptr = NULL;
addr = SDRAM0 + 0x11800; //see Table above
ptr = (UInt32 *) addr;
```

## 6.6 Low power SDRAM (BRC)

Writing 0x23 to the Mode Register implies the following:

- Burst length = 8
- Burst type = Sequential
- CAS latency = 2
- Operating mode = Standard Operation
- Write burst mode = Programmed Burst Length.

Writing 0x00 to the Extended Mode Register, implies the following:

- Partial array self-refresh = All Banks
- Temperature compensated self-refresh = 70°C.

Offset mode register settings are given in [Table 3–74](#).

Table 74. Low power SDRAM address mapping (BRC)

SDRAM size (Mbit)	Total SDRAM size	Bit places shifted (bit)	Offset mode register address <a href="#">[1]</a>	Offset Extended mode register address <a href="#">[2]</a>
16 (1Mx16)	2 MB	9	0x04600	0x0100000
16 (2Mx8)	4 MB	10	0x08C00	0x0200000
64 (4Mx16)	8 MB	9	0x04600	0x0200000
64 (8Mx8)	16 MB	10	0x08C00	0x0800000
128 (8Mx16)	16 MB	10	0x08C00	0x0800000
128 (16Mx8)	32 MB	11	0x11800	0x0800000
256 (16Mx16)	32 MB	10	0x08C00	0x0800000
256 (32Mx8)	64 MB	11	0x11800	0x2000000
512 (32Mx16)	64 MB	11	0x11800	0x2000000
512 (64Mx8)	128 MB	12	0x23000	0x4000000

[1] Base address of the SDRAM is 0x3000 0000 for programming mode register.

[2] Base address of the SDRAM is 0x3000 0000 for programming extended mode register.

Example:

Initialization of the mode register of a low power SDRAM 256 Mbit (16M x 16) with BRC address mapping:

```
#define SDRAM0_BASE 0x30000000
#define SDRAM0 SDRAM0_BASE
int addr;
UInt32 *ptr = NULL;
addr = SDRAM0 + 0x8C00; //see Table above
ptr = (UInt32 *) addr;
```

## 6.7 MPMC\_testmode1 register configuration by measurement

MPMC\_testmode1 should be set to 0x20 (when base frequency is 24 MHz).

When the MCPC is configured for a certain SDRAM, the duration of the SDRAM refresh period can be measured using the following method:

1. Enable the clock-gating of the SDRAM (bits 0 and 1 of the MpmcDyCntl then should be '0')
2. Perform the SDRAM initialization, without any clock-initialization
3. Stop the system
4. Now measure the MPMC\_clkout pin using an oscilloscope and trigger it do a one-shot measurement
5. Count the amount of clock-cycles used by the SDRAM refresh

This needs to be measured once only for a specific type of SDRAM:

- Check MPMC setting with sdram configuration used.

Now:  $mpmc\_testmode1 = \text{<amount of measured clocks>} * \text{fracdiv\_setting\_highspeed}$ .

**Remark:** The fractional divider\_setting\_highspeed determines how much faster the base runs than the AHB clock. The 'amount of measured clocks' are AHB cycles.

## 1. Introduction

---

The EBI module acts as multiplexer with arbitration between the NAND flash and the SDRAM/SRAM memory modules connected externally through the MPMC.

The main purpose of using the EBI module is to save external pins. However only data and address pins are multiplexed. Control signals towards and from the external memory devices are not multiplexed.

### 1.1 Feature list

- Multiplexing of 16 bit data and 16 bit address signals.
- Two ports of three ports are connected to support MPMC and NAND flash.
- Request, Grant, and Back off mechanism is used for arbitration.
- In case of equal priority and simultaneous requests, a round-robin scheme is used.
- Priority can be set per port via software.

## 2. General description

---

### 2.1 Block diagram

[Figure 4–10](#), shows the block diagram of the EBI module with all connected modules.

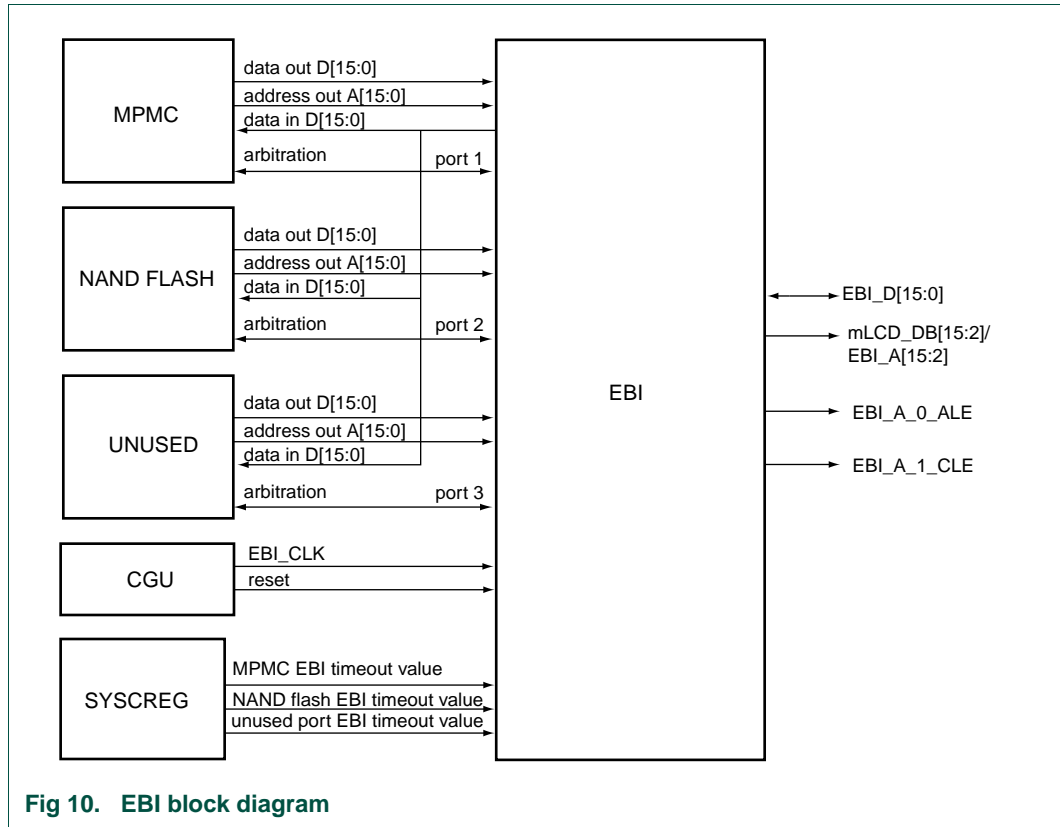

Fig 10. EBI block diagram

## 2.2 Interface description

### 2.2.1 Clock Signals

[Table 4–75](#) gives detailed information about the clock that is connected to the EBI module.

Table 75. EBI Module Clock Overview

Clock Name	I/O	Source/ Destination	Description
EBI_CLK	I	CGU	Main Clock off the module. This clock should run on the same clock as the highest clock on which the external memory controllers are running.

When external memory controllers run on different clock frequencies following restriction should be applied:

- All of the clocks must be synchronous and an integer multiple of each other.
- The fastest clock should also be connected to the EBI\_CLK.

### 2.2.2 Reset Signals

The CGU creates an asynchronous low-active reset signal (nPOR) that resets the logic in the EBI\_CLK domain.

### 2.2.3 External memory controller interface signals

In total, three external memory controller interface ports are available on the EBI module. On the LPC315x two ports are used: port 1 for the MPMC and port 2 for the NAND flash controller. Port 3 is not connected.

### 2.2.4 External Pin Connections

[Table 4–76](#) shows all external pin connections towards and from external memory devices.

**Table 76. EBI external pin connections**

Name	Type	Reset Value	Description
mLCD_A[15:2]/ EBI_A[15:2]	O	-	16 bit address output towards all connected external memories.
EBI_A_0_ALE	O	-	
EBI_A_1_CLE	O	-	
EBI_D[15:0]	I/O	-	16 bit data towards and from all connected external memories.

## 3. Register overview

The EBITIMEOUTVALUE signals for ports one to three signals are connected to software registers that reside in the SYSCREG module. [Section 4–4.2](#) will describe in more detail about the usage of the EBITIMEOUTVALUE registers/ports.

## 4. Functional description

### 4.1 Arbitration

The arbitration inside of the EBI module is explained in the example that follows.

An external memory controller 1 can indicate via its EBIREQ1 signal that it needs external bus access. The EBI module will wait until the currently granted external memory controller 2 is finished, by looking to its EBIREQ2 signal to go low. After that the external memory controller 1, which requested external bus access will be granted access to the external bus via its EBIGNT1 signal. In case the requesting external memory controller 1 has a higher priority then the already granted external memory controller 2, the back off mechanism is used. An EBIBACKOFF2 signal is sent to external memory controller 2, which indicates that external memory controller 2 should end its current external bus access as soon as possible, by making EBIREQ2 low. In that case, EBIGNT2 can go low, and EBIGNT1 can go high.

See [Figure 4–11](#).

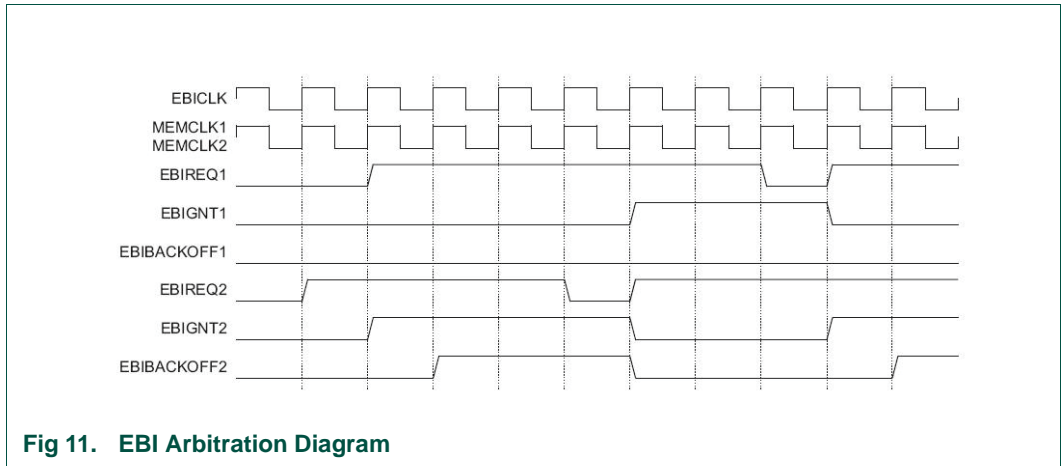

Fig 11. EBI Arbitration Diagram

### 4.2 Priority

The EBITIMEOUTVALUE is used to set the priority. When an external memory controller 1 is producing a request, its EBITIMEOUTVALUE is loaded in a register. When the counter reaches zero, the BACKOFF signal is sent to the external memory controller that currently occupies the external bus. When more requests are sent but the EBITIMEOUTVALUE settings are different, the counter that first reaches zero is given the highest priority so gets its EBIGNT signal set to access the bus. When priorities are equal, a round-robin mechanism is used.

### 4.3 Clock restrictions

All clocks shall be synchronous, and an integer multiple of each other. The fastest clock should also be connected to the EBICLK. The example below indicates that EBICLK is equal to MEMCLK1. MEMCLK2 is equal to half of the EBICLK frequency illustrates what is described above.

Fig 12. Timing Restrictions

## 5. Power optimization

---

The EBI module has clock gating inserted via synthesis.

## 6. Programming guide

---

The EBI module has an internal arbitration mechanism, which does not need any programming. The only thing which can be programmed, is the priority of the different ports. This can be done by programming values in the EBITIMEOUTVALUE1..3 registers, which reside in the SYSCREG module. The lower the programmed value is, the higher the priority of that port is. By default in the LPC315x port 1 (MPMC) has the highest priority. Port 2 (NAND flash) and 3 (not used) have equal priority.

## 1. Introduction

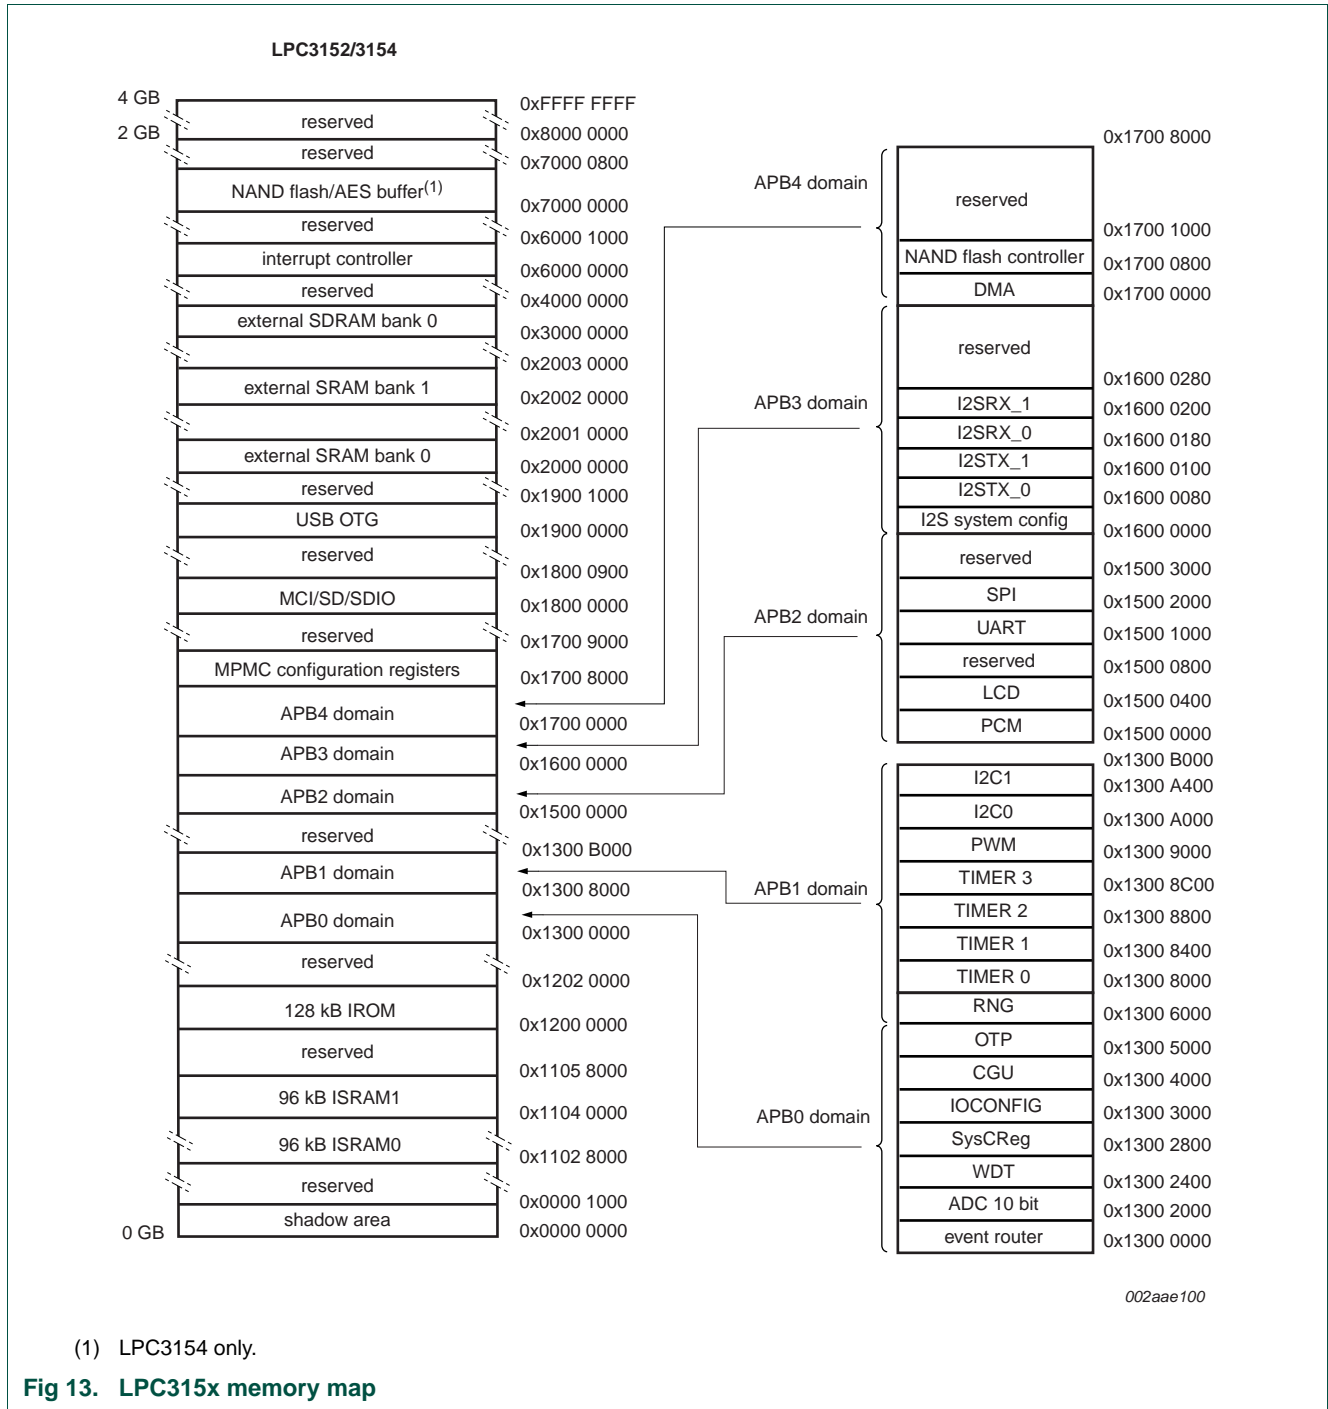

The memory map provides information about the memory address space of all internal registers and memory definitions for both internal and external memories. For more detailed information use the module chapters of this document.

See [Section 30–3](#) for the register map of the analog die.

**Table 77. General address map**

Module	Max Address Space		Data Width	Device Size	Remark
Shadow Space	0x0000 0000	0x0000 0FFF		4 kByte	
Internal SRAM 0	0x1102 8000	0x1103 FFFF	32 bit	96 kByte	
Internal SRAM 1	0x1104 0000	0x1105 7FFF	32 bit	96 kByte	
Internal SROM 0 EROM 0	0x1200 0000	0x1201 FFFF	32 bit	128 kByte	
NANDFLASH buffer	0x7000 0000	0x7000 07FF	32 bit	2 kByte	
External SRAM 0	0x2000 0000	0x2000 FFFF	8 bit	64 kByte	When MPMCSTCS0 is configured for 8bit device.
-	0x2000 0000	0x2001 FFFF	16 bit	128 kByte	When MPMCSTCS0 is configured for 16bit device.
External SRAM 1	0x2002 0000	0x2002 FFFF	8 bit	64 kByte	When MPMCSTCS1 is configured for 8bit device.
-	0x2002 0000	0x2003 FFFF	16 bit	128 kByte	When MPMCSTCS1 is configured for 16bit device.
External SDRAM 0	0x3000 0000	0x37FF FFFF	16 bit	128 MByte	
Peripherals	0x1300 0000	0x1300 7FFF	32 bits	32 kByte	APB0
	0x1300 8000	0x1300 BFFF	32 bits	16 kByte	APB1
	0x1500 0000	0x1500 3FFF	32 bits	16 kByte	APB2
	0x1600 0000	0x1600 03FF	32 bits	1 kByte	APB3
	0x1700 0000	0x1700 0FFF	32 bits	4 kByte	APB4
	0x1700 8000	0x1700 8FFF	32 bits	4 kByte	MPMC cfg
	0x1800 0000	0x1800 03FF	32 bits	1 kByte	MCI
	0x1900 0000	0x1900 0FFF	32 bits	4 kByte	USB OTG
	0x6000 0000	0x6000 0FFF	32 bits	4 kByte	Interrupt controller

## 1. Introduction

---

The internal ROM memory is used to store the boot code of the LPC315x. After a reset, the ARM processor will start its code execution from this memory. The boot process for the LPC3154 is similar to the LPC3152. However, the LPC3154 uses SHA1 hash checking and AES decryption for secure booting.

### 1.1 Feature list

The LPC3154 ROM has the following features:

- Supports **secure** booting from SPI flash, NAND flash, SD/SDHC/MMC cards, UART, and USB (DFU class) interfaces.
- Supports SHA1 hash checking on the boot image.
- Supports **non-secure** booting from UART and USB (DFU class) interfaces during development. Once the AES key is programmed in the OTP, only **secure** boot is allowed through UART and USB.
- Supports **secure** booting from managed NAND devices such as moviNAND, iNAND, eMMC-NAND and eSD-NAND using SD/MMC boot mode.

The LPC3152 ROM has the following features:

- Supports **non-secure** booting from SPI flash, NAND flash, SD/SDHC/MMC cards, UART, and USB (DFU class) interfaces.
- Supports option to perform CRC32 checking on the boot image.
- Supports **non-secure** booting from UART and USB (DFU class) interfaces during development.
- Supports **non-secure** booting from managed NAND devices such as moviNAND, iNAND, eMMC-NAND and eSD-NAND using SD/MMC boot mode.

Features common to all devices:

- Contains pre-defined MMU table (16 kB) for simple systems available at location 0x1201 C000.
- Contains CRC32 lookup table to aid in faster computation of CRC32. Accessible at location 0x1201 5CBC.
- Full implementation of AHB protocol compliant to AMBA specification (Rev 2.0).
- Configurable latency (0, 1, 2 AHB wait states) through SYSCREG\_ISROM\_LATENCY\_CFG (address 0x1300 2860) register (see [Table 27-554](#)).
- ROM capacity of 128 kB.

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock signals

The CGU will provides the clock for the ISROM module (see [Table 6–78](#)).

**Table 78. ISROM module clock overview.**

Clock name	I/O	Source/ destination	Max Freq	Description
ISROM_CLK	I	CGU	75 MHz	Main clock of the module - runs all internal logic.

#### 2.1.2 Reset signals

The CGU provides an asynchronous low-active reset (AHB\_RST\_N) which resets the logic in the ISROM\_CLK clock domain.

#### 2.1.3 DMA Transfers

The ISROM module does not make use of flow control, but is able to make use of DMA via the DMA module.

## 3. Register overview

The ISROM latency configuration registers resides in the SYSCREG module (see [Section 27–4.5](#)).

## 4. Functional description

All of the ARM cores are configured to start executing the code upon reset with the program counter being set to the value 0x0000 0000. The design of LPC315x is such that the first 4 kB page of the ROM (starting at 0x1200 0000) is shadowed upon reset over the first 4 kB page of the address space of the processor. This ensures that the first code executed in the system is the boot code of the ROM. The boot code starts with position independent set of instructions that branches the execution of the code to the address space occupied by the ROM, thus removing the limitation of 4 kB for the code size.

The boot ROM determines the boot mode based on reset state of GPIO0, GPIO1, and GPIO2 pins. To ensure that GPIO0, GPIO1 and GPIO2 pins come up as inputs, pins TRST\_N and JTAGSEL must be low during power-on reset, see JTAG chapter for details. [Table 6–79](#) shows the various boot modes supported on the LPC315x.

**Table 79. LPC315x boot modes**

Boot mode	GPIO0	GPIO1	GPIO2	Description
NAND	0	0	0	Boots from NAND flash. If proper image is not found, boot ROM will switch to DFU boot mode.
SPI	0	0	1	Boot from SPI NOR flash connected to SPI_CS_OUT0. If proper image is not found, boot ROM will switch to DFU boot mode.
DFU	0	1	0	Device boots via USB using DFU class specification.

Table 79. LPC315x boot modes

Boot mode	GPIO0	GPIO1	GPIO2	Description
SD/MMC	0	1	1	Boot ROM searches all the partitions on the SD/MMC/SDHC/MMC+/eMMC/eSD card for boot image. If partition table is missing, it will start searching from sector 0. A valid image is said to be found if a valid image header is found, followed by a valid image. If a proper image is not found, boot ROM will switch to DFU boot mode.
Reserved 0	1	0	0	Reserved for testing.
NOR flash	1	0	1	Boot from parallel NOR flash connected to EBI_NSTCS_1. <sup>[1]</sup>
UART	1	1	0	Boot ROM tries to download boot image from UART ((115200 – 8 – n -1) assuming 12MHz FFAST clock).
Test	1	1	1	Boot ROM is testing ISRAM using memory pattern test. After test switches to UART boot mode.

[1] For security reasons this mode is disabled when JTAG security feature is used.

## 4.1 Boot process

LPC315x top level boot process is illustrated in [Figure 6–14](#). The boot ROM reads the OTP polyfuses into the data register as described in the OTP chapter (see [Section 19–5](#)). Based on the values of security fuses the JTAG access to the chip is enabled. By default the JTAG access to the chip is disabled at reset. In the LPC315x, the boot ROM will also set the 'lic\_ctrl\_cs\_bit' bits in the OTGDCLIC register of the analog die ([Table 30–612](#)) with the value read from fuses 505 to 508 (see [Figure 19–49](#)).

As shown in the picture the boot ROM determines the boot mode based on the reset state of the pins GPIO0, GPIO1 and GPIO2. The boot ROM indicates any error during boot process by toggling GPIO2 pin hence it is advised to connect this pin to a LED to get visual feedback. Boot ROM copies/downloads the image to internal SRAM at location 0x1102 9000 and jumps to that location (sets ARM's program counter register to 0x1102 9000) after image verification. Hence the images for LPC315x should be compiled with entry point at 0x1102 9000. On LPC3152 the image and header are validated using CRC32 checksum algorithm. While on LPC3154 the image and header are validated using a 160-bit SHA1 hash algorithm.

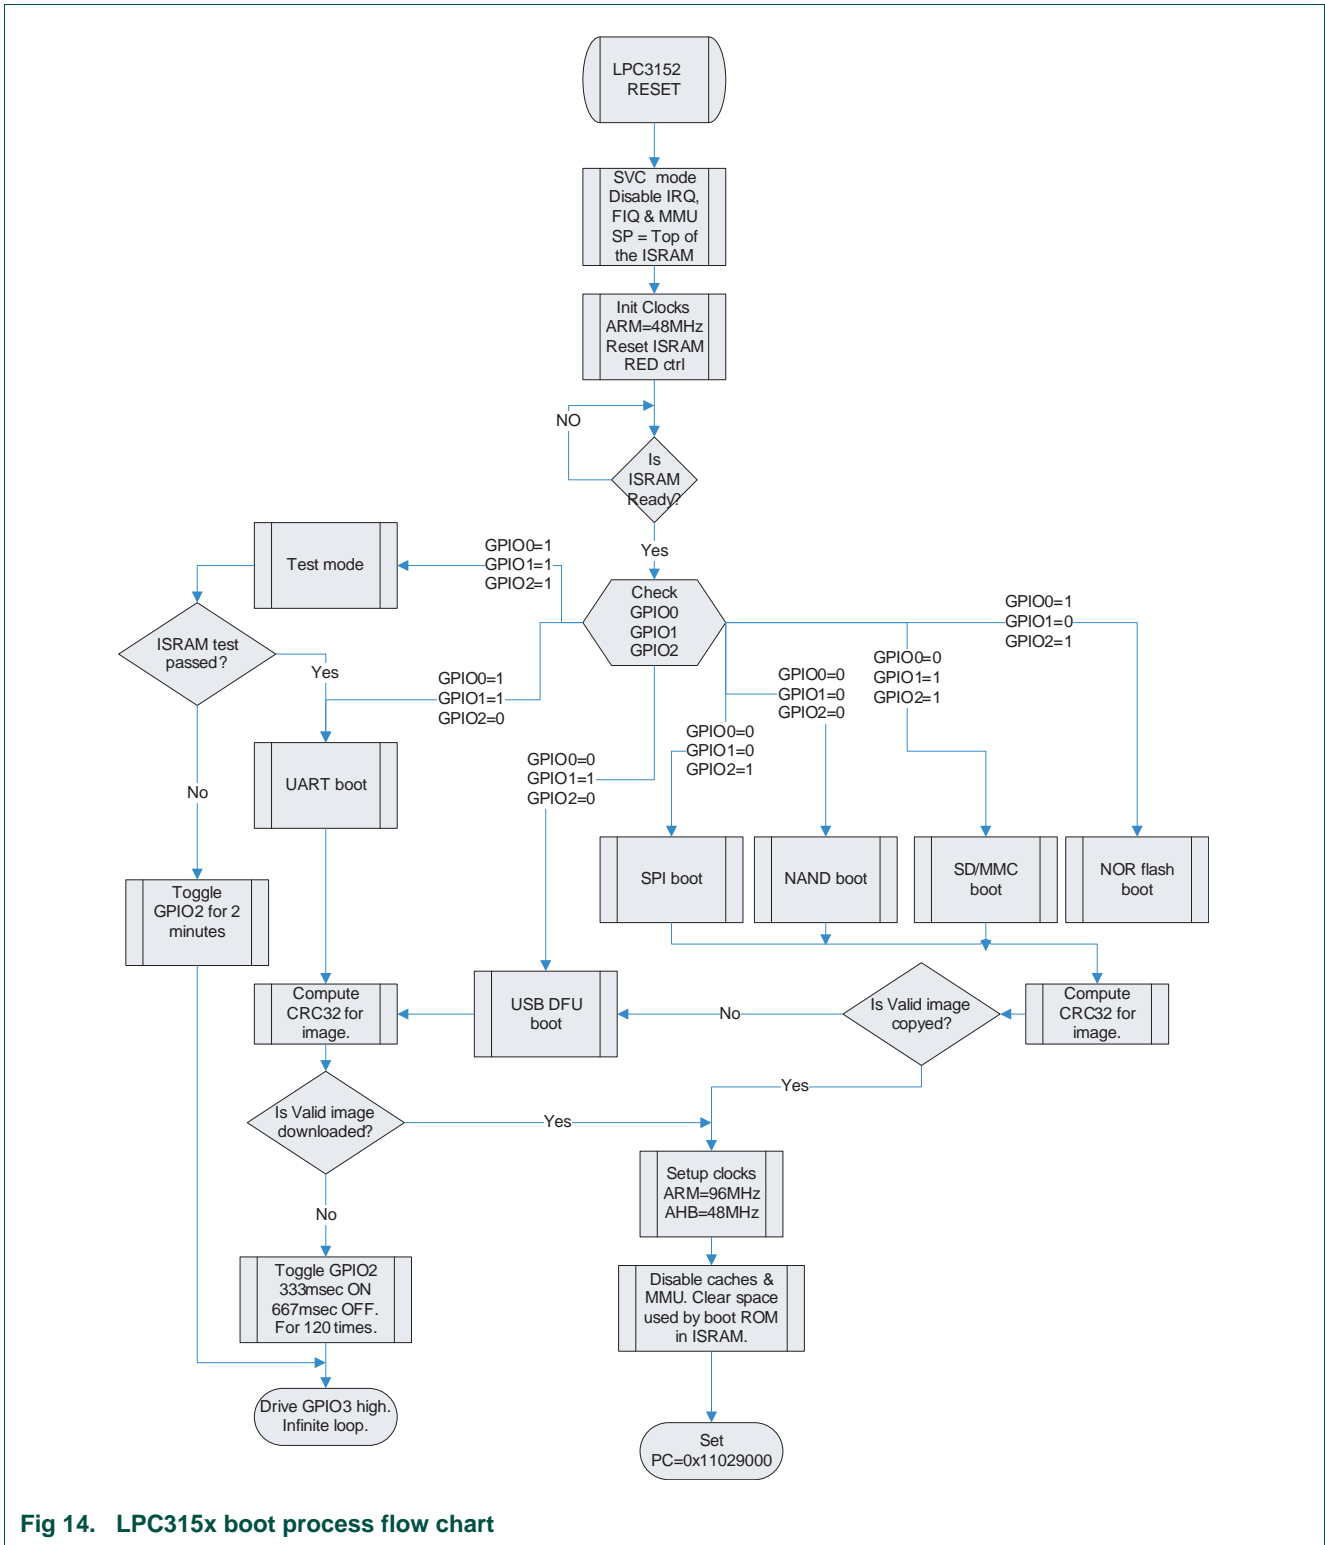

Fig 14. LPC315x boot process flow chart

## 4.2 Boot image format

LPC315x boot ROM expects the boot image be compiled with entry point at 0x1102 9000 and has the layout described in the [Table 6–80](#) (except for “Parallel NOR flash” boot mode).

**Table 80. LPC3152 Image format**

Field Name	Offset	Size in bytes	Description
<b>Image Header</b>			
vector	0x00	4	Valid ARM instruction. Usually this will be a branch instruction to entry point of the image.
magic	0x04	4	This field is used by boot ROM to detect a valid image header. This field should always be set to 0x41676d69.
execution_crc32	0x08	4	CRC32 value of execution part of the image (offset 0x80 onwards). If the 'image_type' is set to '0xA', this field is ignored by boot ROM.
Reserved0	0x0C	16	Should be zero.
imageType	0x1C	4	Specifies whether CRC check should be done on the image or not. 0xA – No CRC check required. 0xB – Do CRC32 check on both header and execution part of the image.
imageLength	0x20	4	Total image length including header rounded up to the nearest 512 byte boundary. In C language the field can be computed as: $imageLength = (Actual\ length + 511) \& \sim 0x1FF;$
releaseID	0x24	4	Release or version number of the image. Note, this field is not used by boot ROM but is provided to track the image versions.
buildTime	0x28	4	Time (expressed in EPOCH time format) at which image is built. Note, this field is not used by boot ROM but is provided to track the image versions.
sbzBootParameter	0x2C	4	Should be zero.
cust_reserved	0x30	60	Reserved for customer use.
header_crc32	0x6C	4	CRC32 value of the header (bytes 0x00 to 0x6C of the image). If the 'image_type' is set to '0xA', this field is ignored by boot ROM.
Reserved1	0x70	16	Should be zero.
<b>Execution Part</b>			
Program code	0x80	Max. 128 kB	Program code. The maximum size of the image allowed by boot ROM is 128 kB (including header). The final image has to be padded to the nearest 512 byte boundary.

## 4.3 NAND boot mode

Figure “NAND boot flow” details the boot-flow steps of the NAND boot mode. As already mentioned, the execution of this mode happens only if the mode pins had proper value on reset (see [Table 6–79](#)).

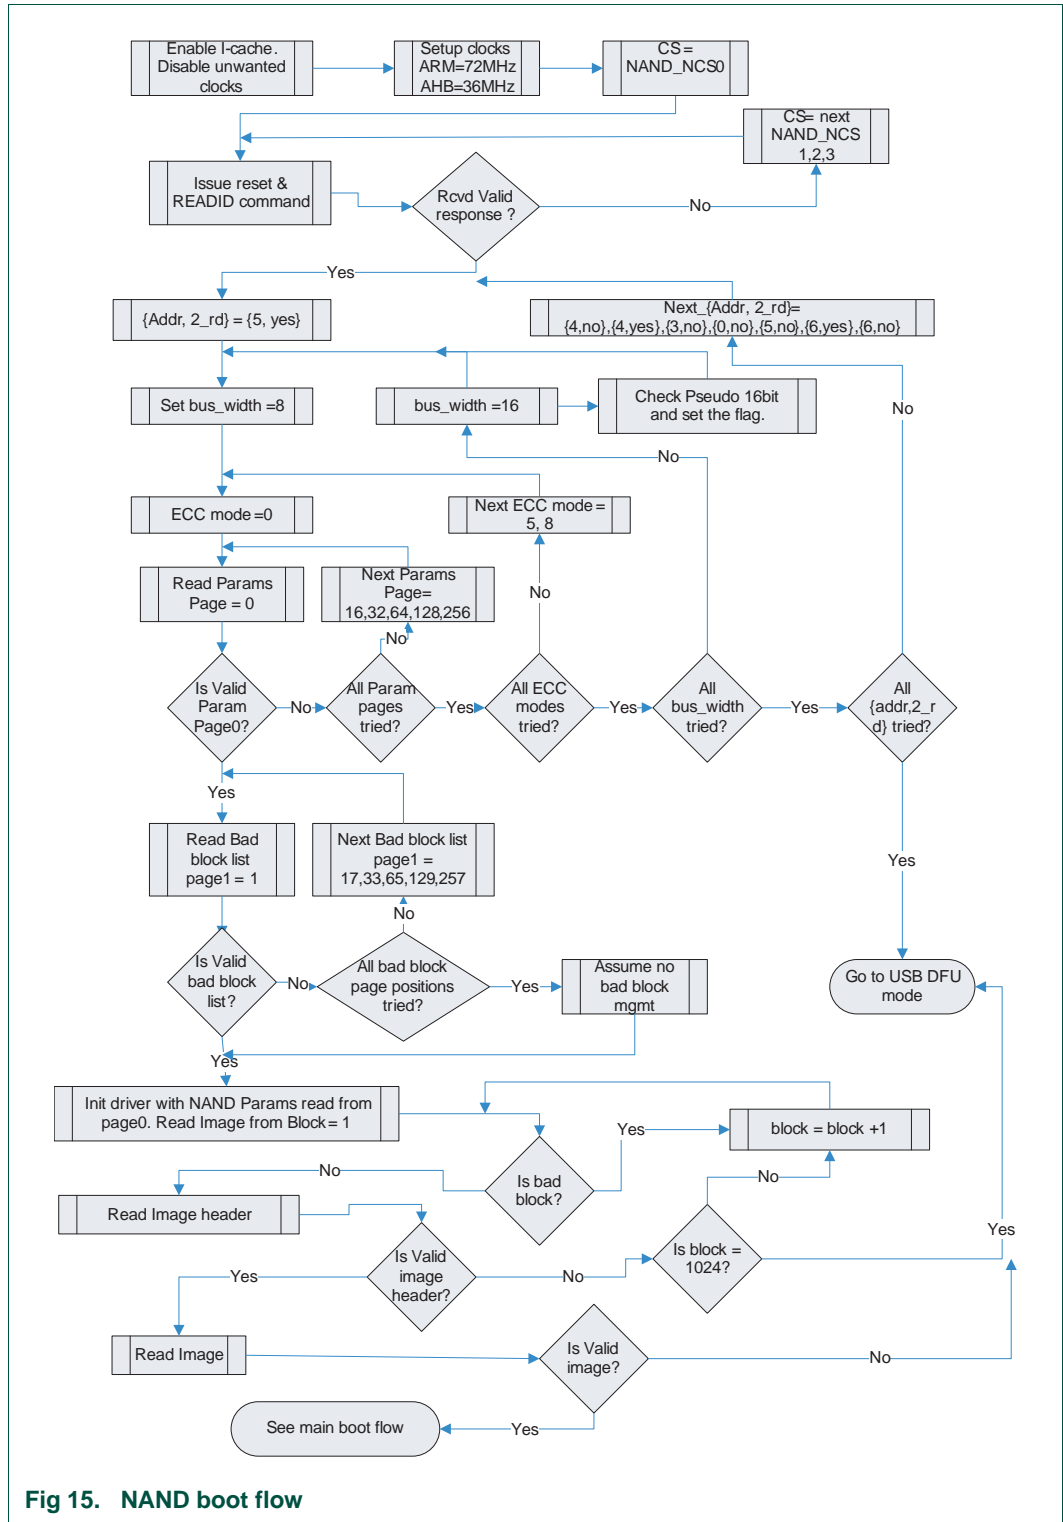

Fig 15. NAND boot flow

### 4.3.1 NAND parameters

The boot ROM expects the NAND flash device settings. The bad block list information is written in block zero. The LPC315x boot ROM defines NAND flash parameters page as below:

Table 81. NAND flash parameters

Field Name	Offset	Size in bytes	Description
tag	0x00	8	Parameter page marker. This field should always be set as ASCII string "NANDflash".
interface_width	0x08	1	This field should be set to 0x10 when 16-bit NAND device is connected. Boot ROM assumes 8-bit NAND device if any other value is set in this field.
reserved	0x09	1	Should be zero.
page_size_in_bytes	0x0A	2	Page size in bytes. For small page NAND flash set to 512.
page_size_in_32bit_words	0x0C	2	Page size in number of 32-bit words. For small page NAND flash set to 128.
pages_per_block	0x0E	2	Number of pages per block.
nbr_of_blocks	0x10	4	Number of block present on device.
amount_of_address_bytes	0x14	1	Number of page address cycles expected by device during read/program operations.
amount_of_erase_address_bytes	0x15	1	Number of address cycles expected by device during erase operation.
support_read_terminate	0x16	1	Set non-zero value for devices which require 2nd read command (0x30) cycle.
page_increment_byte_nr	0x17	1	Number of address bytes used for column addressing.
device_name	0x18	40	User defined ASCII string.
timing1	0x40	4	Value to be set in NandTiming1 register.
timing2	0x44	4	Value to be set in NandTiming2 register.
ecc_mode	0x48	1	Set 0 for no hardware ECC. Set 5 to use 5 bit ECC corrector. Set 8 to use 8 bit ECC corrector. Other values are ignored.
Reserved	0x49	3	Should be zero.
User_def	0x4C	176	User defined values.
CRC32	0xFC	4	CRC32 value of the above defined structure.

NAND device manufacturers pre-mark bad blocks on their devices. These marker locations vary from one manufacturer to another. The LPC315x boot ROM code should use this information and skip bad blocks during the boot process. For this purpose, the LPC315x boot ROM defines a bad block list page as part of block 0. The format of the bad block list page is shown below.

Table 82. Bad block list page

Field Name	Offset			Size in bytes	Description
	page_size 512 byte	page_size 2048 byte	page_size 4096 byte		
<b>Page 1</b>					
Bad_block_list_size	0x00	0x00	0x00	4	Size of bad block list
Bad block number	0x04	0x04	0x04	4	First bad block number
Bad block number	0x08	0x08	0x08	4	Second bad block number
...					
Marker	0x1F8	0x7F8	0xFF8	3	Bad page marker. This field should always be set as ASCII string "BAD".
Bad_page_nr	0x1FB	0x7FB	0xFFB	1	Page number. Value = 1.
CRC32	0x1FC	0x7FC	0xFFC	4	CRC32 value of the current page excluding the current word. I.e. CRC32 of bytes 0 to (page_size – 4) of this page.
<b>Page 2</b>					
Bad block number	0x00	0x00	0x00	4	Bad block number m, where $m = \text{page\_size}/4 - 3 + 1 = 126/510/1022$ for page_size = 512/2048/4096 byte.
Bad block number	0x04	0x04	0x04	4	Bad block number m + 1.
...					
Marker	0x1F8	0x7F8	0xFF8	3	Bad page marker. This field should always be set as ASCII string "BAD".
Bad_page_nr	0x1FB	0x7FB	0xFFB	1	Page number. Value = 2.
CRC32	0x1FC	0x7FC	0xFFC	4	CRC32 value of the current page excluding the current word, for example CRC32 of bytes 0 to 508 of this page for a 512-byte page.
<b>Last bad block page n</b>					
Bad block number	0x00	0x00	0x00	4	Bad block number $m + (n - 2) \times (m + 1)$ , where $m = \text{page\_size}/4 - 3 = 125/509/1021$ byte.
Bad block number	0x04	0x04	0x04	4	Next bad block number
Marker	0x08	0x08	0x08	3	Bad page marker. This field should always be set as ASCII string "BAD".
Bad_page_nr	0x0B	0x0B	0x0B	1	Page number. Value = n.
CRC32	0x0C	0x0C	0x0C	4	CRC32 value of the current page excluding the current word. I.e. CRC32 of bytes 0 to 12 of this page.

In the above table, the assumption is made that the last bad block page contained only 2 bad block numbers. If the number of bad blocks is less than 125/509/1021 (for a 512/2048/4096-byte device), then the page 1 structure will be as shown in [Table 6–83](#).

The boot ROM always reads one full page (512 byte for small, 2 kB or 4 kB for large) before it parses the bad block list. If ECC is enabled in the parameter page, then the NAND programmer should write the complete page, or else the ECC will fail on subsequent sub-pages. The boot ROM will treat this as an error and not boot from NAND.

Table 83. Bad block list page (page 1)

Field Name	Offset			Size in bytes	Description
	page_size 512 byte	page_size 2048 byte	page_size 4096 byte		
<b>Page 1</b>					
Bad_block_list_size	0x00	0x00	0x00	4	Size of bad block list
bad block number	0x04	0x04	0x04	4	First bad block number
bad block number	0x08	0x08	0x08	4	Second bad block number
...					
Marker	0xYY (where 0xYY < 0x1F8)	0xYY (where 0xYY < 0x7F8)	0xYY (where 0xYY < 0xFF8)	3	Bad page marker. This field should always be set as ASCII string "BAD".
Bad_page_nr	0xYY + 3	0xYY + 3	0xYY + 3	1	Page number. Value = 1.
CRC32	0xYY + 4	0xYY + 4	0xYY + 4	4	CRC32 value of the current page excluding the current word. I.e. CRC32 of bytes 0 to (0xYY+4) of this page.
Unused	0xYY + 8	0xYY + 8	0xYY + 8	0x1F8 – 0xYY – 8 (512 byte) 0x7F8 – 0xYY – 8 (2048 byte) 0xFF8 – 0xYY – 8 (4096 byte)	Fill remaining page with 0xFF

Since boot ROM needs to know the number of address cycles, chip select, timings, device bus width, page size etc. to read the parameter page, it employs the following pseudo-code algorithm to auto-detect and read the NAND parameter page. Once it reads the parameter page, it uses the values configured in that page to access the NAND device.

1. For each chip select (NAND\_NCS\_0 to NAND\_NCS\_3) repeat steps 2 to 12.
2. Determine if it is a pseudo 16-bit setup. A pseudo 16-bit setup is defined as connecting two identical 8-bit wide NAND devices (same manufacturer and same product type) in parallel to LPC315x to create a 16-bit wide device. Boot ROM sends READID command on both upper and lower byte of 16-bit NAND bus and checks if the responses received on both upper byte and lower byte of the bus are identical.
3. If the device is pseudo 16-bit, from now onwards repeat command and address bytes on both upper and lower byte of the bus. As far as data is concerned treat the device as a 16-bit wide device.
4. If no response is received, check the presence of device on next chip select.
5. Initially assume 8-bit wide device and do the following steps.
6. Access the NAND device assuming number of address cycles & requires 2nd read command (0x30) cycle in the following order: {address cycles, Command 0x30 required} {5,yes},{4,no},{4,yes},{3,no},{0,no},{5,no},{6,yes},{6,no}.
7. Issue reset to NAND device every time the access method is changed.
8. Read page with hardware ECC check disabled.

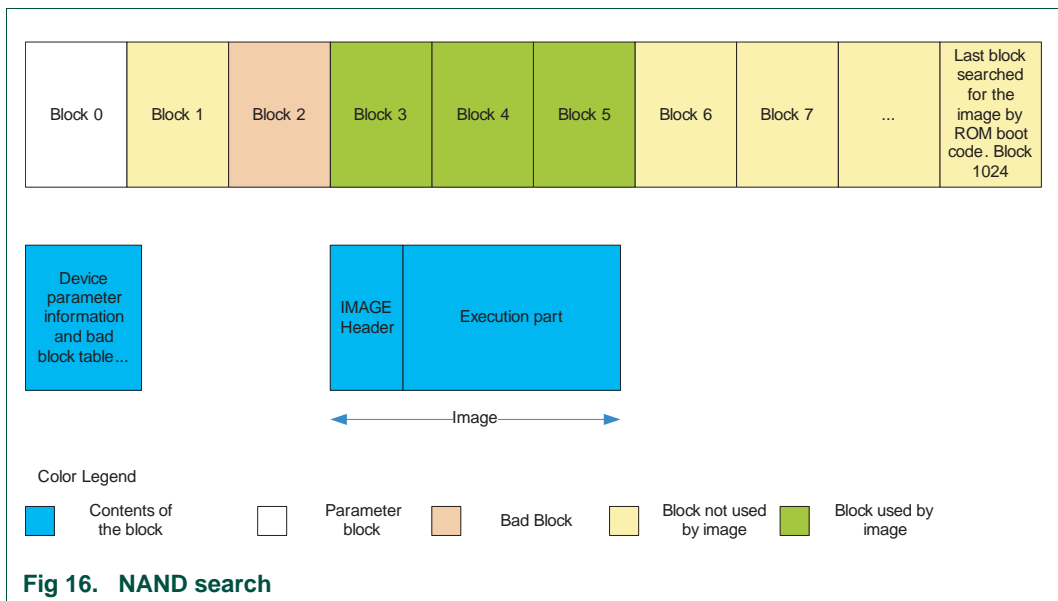

9. Check whether the page has parameter information. Verification involves checking the presence of parameter marker (ASCII string "NANDflsh") at offset 0x00 and also checking whether the CRC32 of the parameter page matches the value set at offset 0xFC.
10. Repeat read page (steps 7 and 8) with hardware ECC set to 5-bit mode and then 8-bit mode.
11. Repeat steps 7 to 9 until a valid parameter page is found using following page indexes: 0, 16, 32, 64, 128, 256.
12. If no valid parameter page is found repeat steps 5 to 10 assuming 16-bit device.

Once the boot ROM reads the parameter page it employs the following algorithm to read bad block list.

1. Repeat the following steps 2 to 3 until valid bad block list is found using current page index as: 1, 17, 33, 65 and 257.
2. Check the page has valid bad block "page 1" information. See "Bad block list pages" table for more information on page structure.
3. Read next pages until all bad block numbers are read. Note, the first page contains the "Bad\_block\_list\_size" field which tells boot ROM how many blocks are marked bad on this device.

### 4.3.2 Search for the valid NAND flash executable image

The first step in the execution of the image from the NAND flash is the search for it. The search for the valid image starts at the block 1 of the NAND flash. Block 0 of the NAND flash is filled in with the information about initial bad blocks and information about the geometry of the NAND flash itself, used during the initialization of the ROM based NAND flash driver. This can be seen in [Figure 6–16](#).

It is recommended that the application which stored the image on the NAND flash, should make sure that it occupies a contiguous set of good physical blocks, so there is no need for the bad block management scheme to be implemented in the ROM boot. Boot ROM

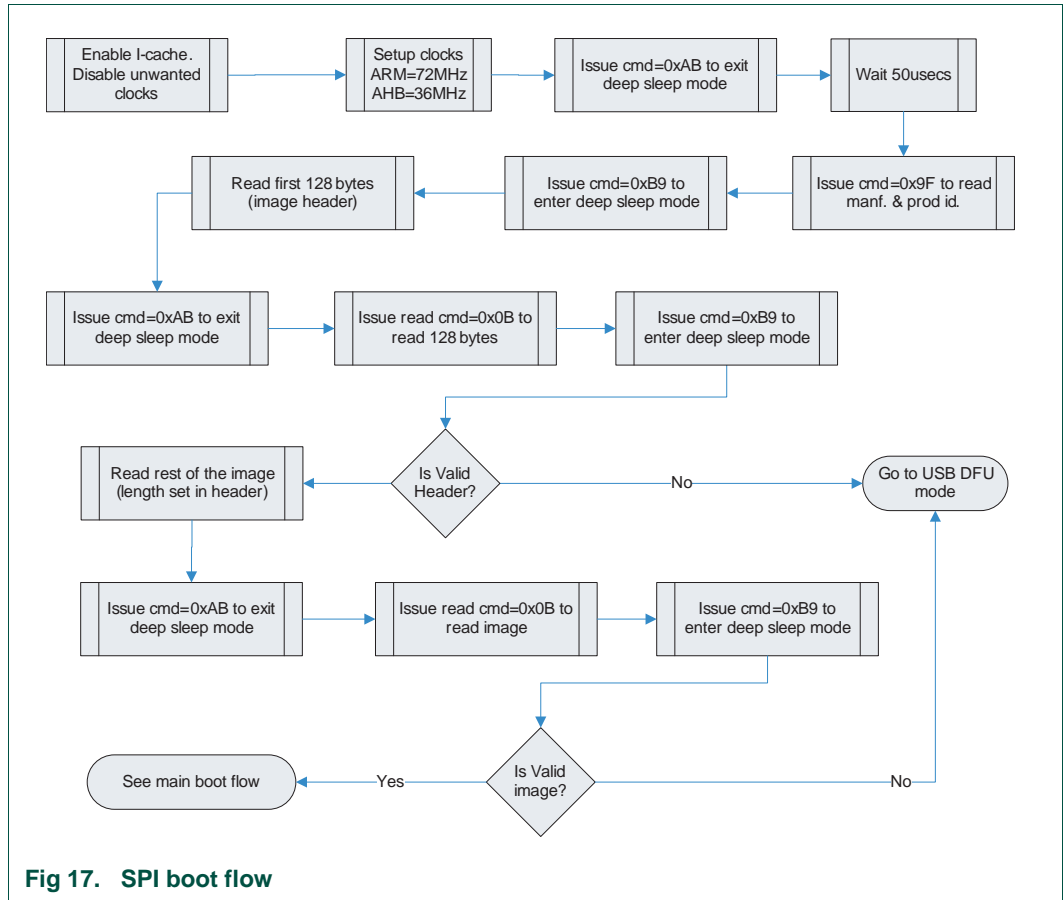

skips bad blocks as long as the bad block is listed in the bad block list page. In the example in [Figure 6–16](#) the image occupies 3 blocks, and the first free set of the contiguous 3 blocks are blocks 3 to 5. The search process tries to find appropriate header in block 1 and fails. The header check is started by loading 128 bytes from the beginning of the current block (block 1 in this case) and checking the magic word first. There is a high probability that the block that does not contain header has an incorrect magic word value, so no more time is spent on this block and next block can be searched. If the magic word value was correct, the challenging of the header continues by computing the CRC32 (for LPC3152) over header scope and comparing it against the one stored in the header. The probability of an accidental match is quite small. CRC32 check for LPC3152 is done on the execution part of the image, that the computed CRC32 (for LPC3152) matches the one that was stored in the header.

In the example illustrated in [Figure 6–16](#), the normal course of action would be the failed search starting from the block 1, failed search starting from the block 2 and successful search starting from the block 3.

The LPC315x boot ROM searches for valid image starting from Block 1 to block 1024 (if present on the device). If a bad block is present in between the image blocks and the block is listed in bad block list page, the boot ROM skips that block and assumes the consecutive blocks have the rest of the image.

#### 4.4 SPI NOR-flash boot mode

[Figure 6–17](#) details the boot-flow steps of the SPI NOR-flash boot mode. As already mentioned, the execution of this mode happens only if the mode pins had proper value on reset (see Boot modes [Table 6–79](#)).

As illustrated in the figure [Figure 6-17](#), for LPC315x boot ROM to support a SPI NOR-flash boot, the device should support “High frequency continuous array read” (command 0x0B). Since boot ROM doesn’t rely on response for commands 0xAB, 0xB9 and 0x9F, as long as the SPI devices ignore or respond correctly to these command LPC315x should be able to boot from them.

#### 4.5 DFU boot mode

Device Firmware Upgrade (DFU) is a USB class specification defined by USB.org. LPC315x boot ROM uses this class specification to implement USB boot mode. [Figure 6-18](#) details the boot-flow steps of the USB boot mode.

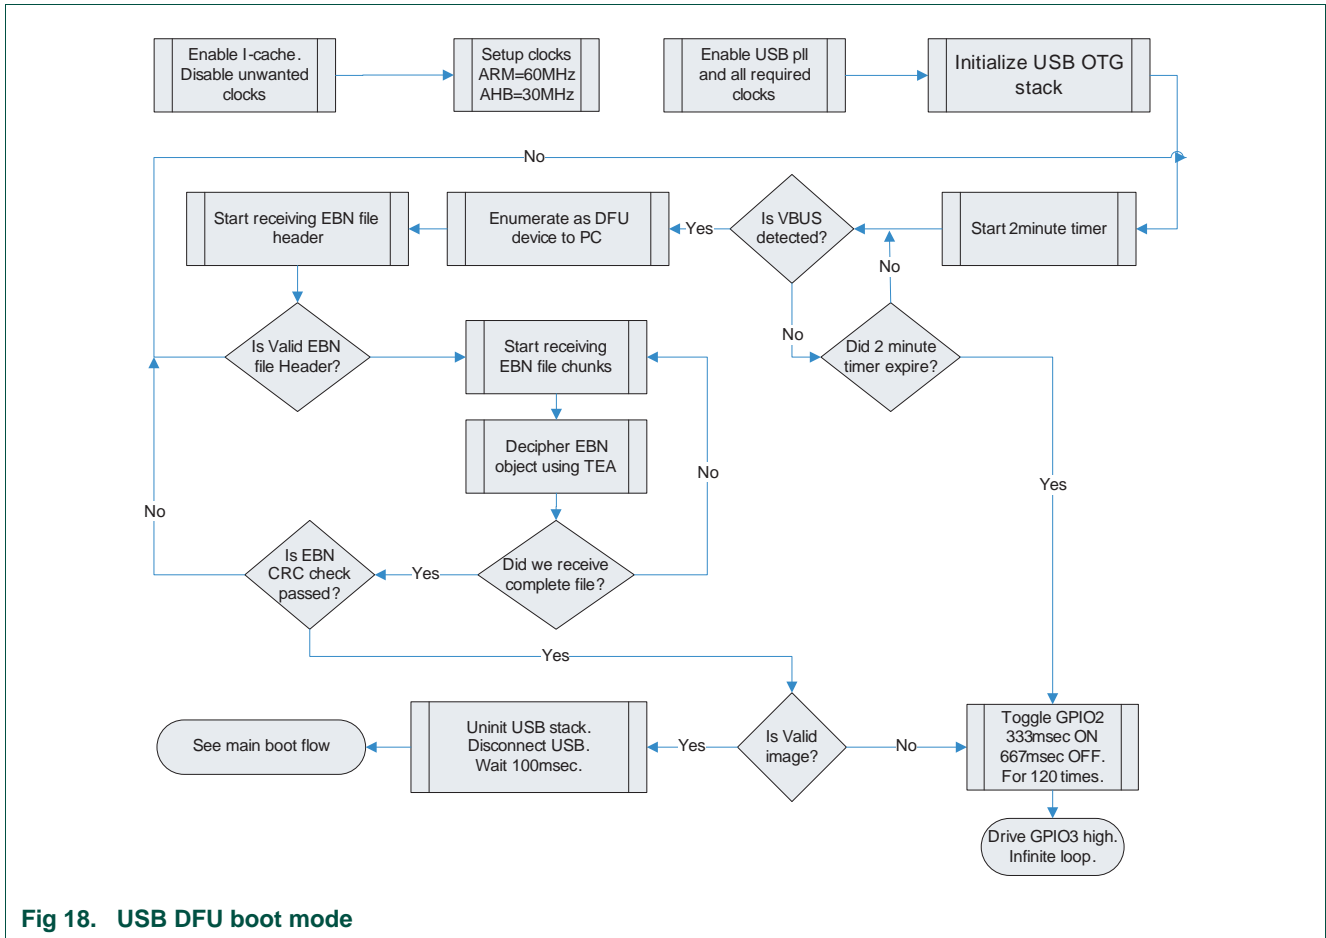

Fig 18. USB DFU boot mode

The boot flows in following steps through the DFU mode:

1. Setup the clocks for DFU mode.
2. Initialize USB OTG stack that implements DFU class.
3. Enable and configure any additional necessary hardware (i.e. supply voltage must be guaranteed to be greater than 3.1 V).
4. Wait for the detection of the connection of the USB host. This is implemented as a polling loop that blocks the execution until condition USB connected is read. When the VBUS of the USB is not detected within 2 minutes, the boot ROM indicates error by toggling GPIO2 for 2 minutes and then driving GPIO3 high.
5. Start downloading the first header of the EBN file. The EBN file is a collection of objects. Each object consists of the header and the TEA (Tiny Encryption Algorithm) encrypted image. Apart from the size of the image, the header indicates the TEA key offset and the 32b CRC of the contained image. If the EBN header indicates the size of the object is larger than 128 KB, an error is signaled to the USB host and the execution is returned to the top, waiting for the USB connection.
6. Download the rest of the EBN image and perform TEA decryption using the key indicated by the key offset in the EBN header.

7. Calculate CRC32 checksum value of the TEA decrypted image and compare it against the value stored in the EBN header. When the hash values do not match, the error is signaled to the host and the execution is returned to the top, waiting for the USB connection.
8. Validate the header of the execution image, using header CRC32 checksum value (only done if image\_type is set to 0xB), checking the magic values, size and image type indicator.
9. Calculate the CRC32 checksum value for execution part of the image (only done if image\_type is set to 0xB) and compare it against the value stored in execution image header. If the calculated and stored checksum values do not match an error is signaled to the USB host and the execution is returned to the top, waiting for the USB connection.

**Table 84. EBN image format**

Field name	Offset	Size (bytes)	Description
Vector	0x00	4	Should always be 0xE600 0010
Starting sector	0x04	4	Each sector is 2048 bytes so if this field is n, then the image will be copied to (0x1102 9000 + (n x 2048)) location.
Key index	0x08	4	Boot ROM has 64 pre-built 128 bit keys. This field tells which key out of 64 is used to encrypt the image. Customers who want to know at least one key value to create their own program can use the Key0 which is 0x91EC6C69 EACEE0D0 6972503A F69228BF.
Initial vector 1	0x0C	4	Initial vector 1 used by TEA encryption.
Initial vector 2	0x10	4	Initial vector 2 used by TEA encryption.
Image CRC	0x14	4	Image CRC. Use the CRC table available in boot ROM.
Image size	0x18	4	Image size in bytes.

## 4.6 SD/MMC boot mode

Figure “SD/MMC boot flow” details the boot-flow steps of the SD/MMC boot mode. As already mentioned, the execution of this mode happens only if the mode pins had proper value on reset (see Boot modes [Table 6–79](#)).

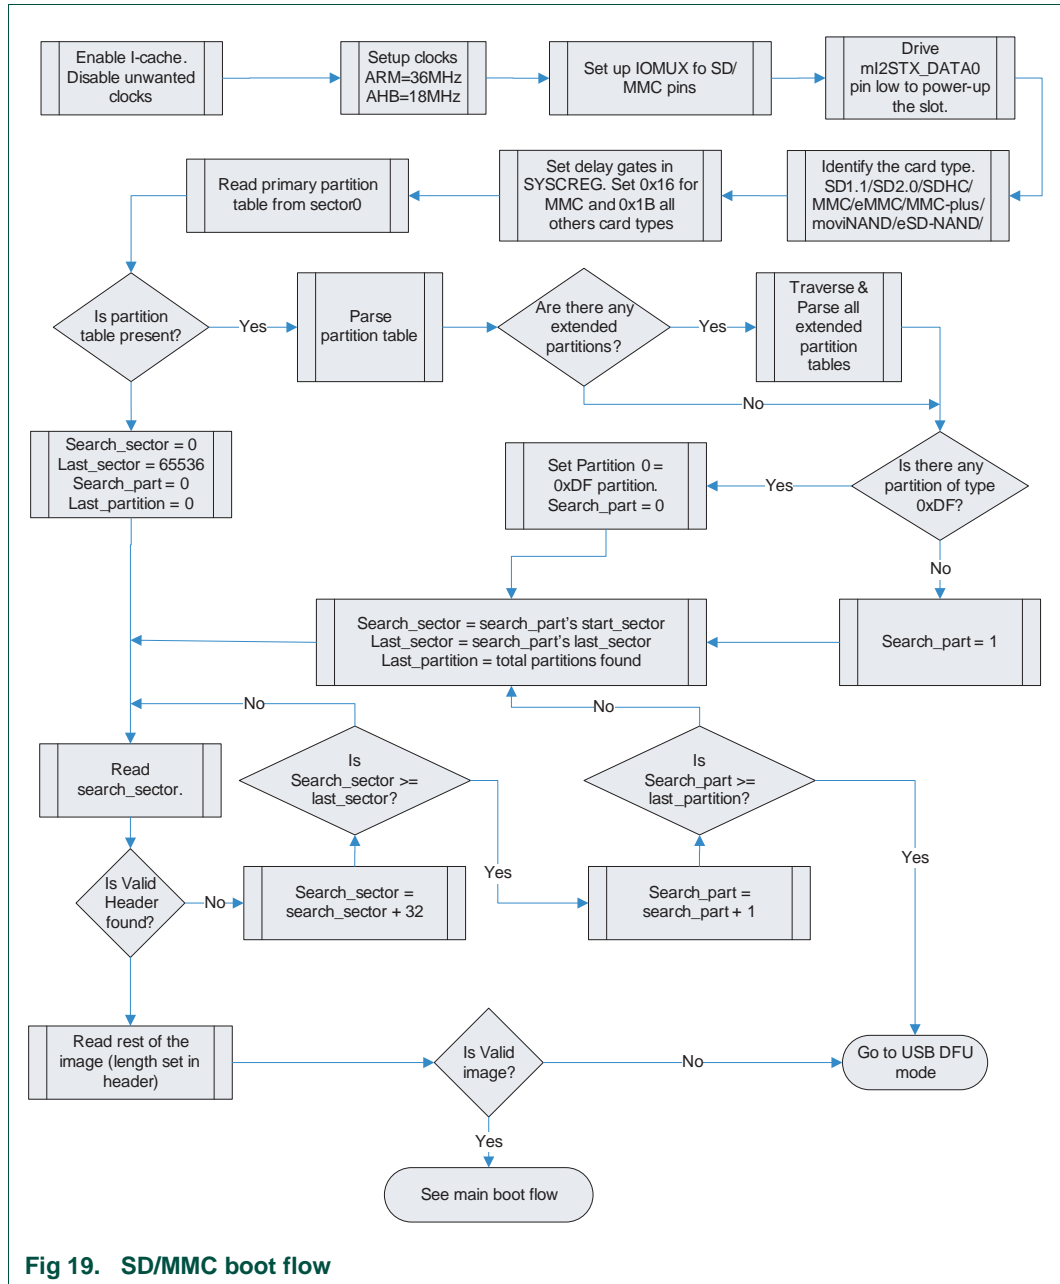

Fig 19. SD/MMC boot flow

As illustrated in [Figure 6-19](#), boot ROM supports parsing of partition tables on the card. The boot ROM doesn't have any knowledge of file system. Hence to boot from SD/MMC cards the user has to create "0xDF" partition and copy the boot image directly to the raw sectors of that partition.

As shown creation of partition type "0xDF" is not a compulsory requirement but, it speeds up the search process. A user could create any other partition type and dump the boot image to that partition.

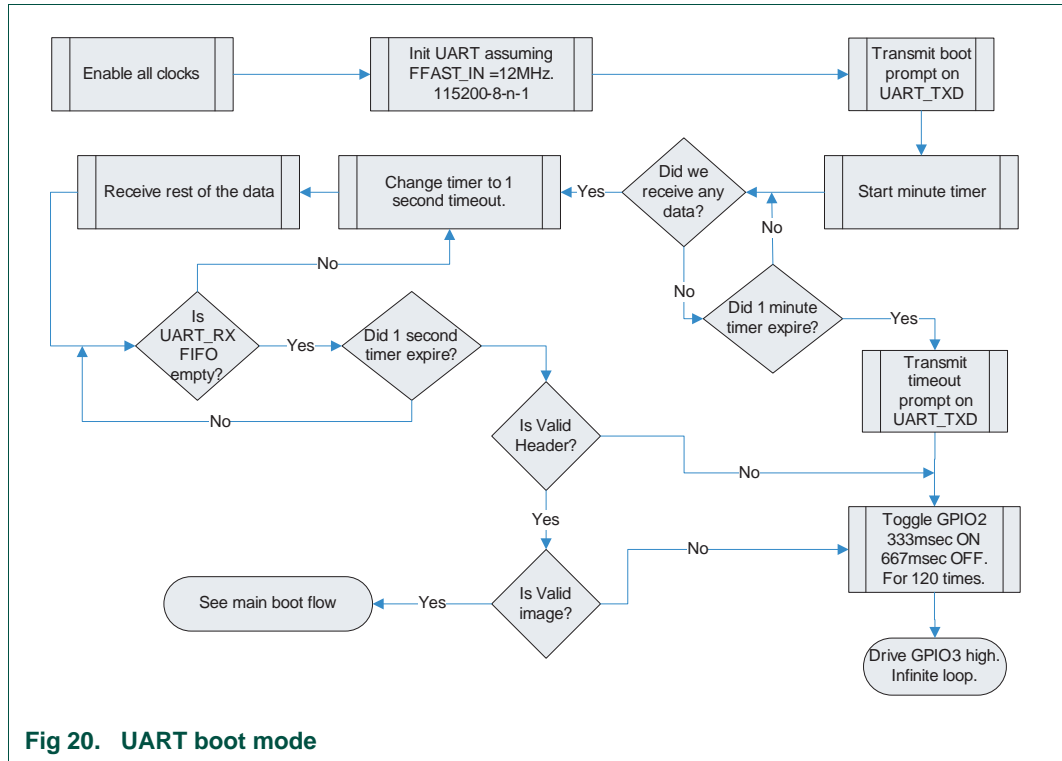

LPC315x boot ROM deploys a comprehensive card detection process to detect MMC, eMMC, SD1.1, SD2.0, SDHC, eSD, managed-NAND and moviNAND devices.

LPC315x boot ROM interacts with memory cards in 1-bit bus mode only.

### 4.7 UART boot mode

Figure 6–20 details the boot-flow steps of the UART boot mode. As already mentioned, the execution of this mode happens only if the mode pins had proper value on reset (see Boot modes Table 6–79).

As illustrated in Figure 6–20 configure UART with following settings:

- Baud rate = 115200 (UART divisor registers are programmed 12MHz crystal frequency)
- Data bits = 8
- Parity = None
- Stop bits = 1

The boot ROM doesn't implement any flow control or any handshake mechanisms during file transfer. Hence it is recommended to create CRC check images (image\_type set to 0xB) for UART boot.

### 4.8 Parallel NOR-flash boot mode

Unlike other boot modes "NOR-flash" boot mode uses simplified image header. When this boot mode is selected boot ROM reads EBI\_NSTCS\_1 chip select area in 16 bit mode. The wait states for the interface are set to default values. See MPMC chapter for details. In this boot mode boot ROM copies the image from NOR-flash to ISRAM0 (location 0x1102 9000) and jumps to that location (sets the program counter of ARM to 0x1102 9000). Also no CRC check is done to validate the image.

LPC315x boot ROM expects the boot image be compiled with entry point at 0x1102 9000 and has the layout described in the table "NOR Image format".

Table 85. NOR image format

Field Name	Offset	Size in bytes	Description
<b>Image Header</b>			
vector	0x00	4	Valid ARM instruction. Usually this will be a branch instruction to entry point of the image.
magic	0x04	4	This field is used by boot ROM to detect a valid image header. This field should always be set to 0x3150F2E5.
imageLength	0x08	4	Total image length including header. Maximum allowed value is 128 kB.

## 4.9 Test mode

On LPX315x, this mode is primarily designed as a ROM based lifetime test of the basic functions of the processor. It is a simple platform that is used for measurements of the quality of the generated audio signal and of the correctness of the recorded line in signal.

**Remark:** Test mode is only meant for test purposes and should not be used in a normal product. Failing to comply with this restriction could provoke unexpected behavior from the board (e.g. USB charge pump is enabled during test mode, and if UOS\_VBUS pin is connected to VBUS rail on board and a USB cable is connected between PC and device, the VBUS will be driven by both board and PC ultimately harming the system).

LPC315x boot ROM does memory pattern tests on ISRAM0 and ISRAM1. If any errors are found during the test, the boot ROM will toggle the GPIO2 pin continuously for 2 minutes and then drive the GPIO3 pin high. See [Figure 6-14](#) for details. If the memory test passes, the boot ROM proceeds with further testing of audio paths.

The blocks being subjected to these tests are the elements of the output audio paths (class-AB amplifiers) and the input (line in). To pass the test successfully, it is required to establish the analog loop back between the headphone output and the line input.

The Test mode is divided into the initialization part and the cyclical tests part. The Test mode can be stopped at any time and move into the UART mode, if the UART wake-up signals, three ASCII dots ('...') in sequence, are sent on the UART. All of the analog blocks are enabled and all of the unused clocks are shutdown. The boot code will also set up one of the DMA channels to continuously fill the designated circular buffer with the audio recorded from the line input.

The remaining tests are put in the following (constantly repeated) sequence:

1. Setup the DMA channel to transfer the sinusoidal signal from the circular memory buffer contained in ROM to the output of the CLASS-AB amplifier. Wait for 1 minute in this state, and while waiting, check for the wake-up from the UART. If UART wake-up is received, immediately stop all of the DMA transfers and disable the analog blocks before branching into the UART mode.
2. After 1 minute, pause the DMA channel that is transferring data recorded from the line input and then analyze the recorded data gathered in the circular buffer. If the data in the buffer is not as expected, generate a report on UART terminal. If the data was as expected, generate a positive report and move to next sinusoidal frequency pair.

At any given moment, the UART wake-up signal ('...') can be sent to move the execution flow into the UART mode.

## 4.10 ISROM latency

The CPU can read boot-code from the ROM via the ISROM module. The CPU will address the ISROM module, which will translate the incoming AHB address in a ROM address. Based on this address the ROM will provide the ISROM module with data, which is stored on the given address. Then the ISROM module will transport the data read from the ROM to the CPU. By changing the latency through the memory controller less or more pipeline stages will be added. The more pipeline stages are used, the higher the frequency is which can be used, but the bigger the latency through the ISROM module is.

## 4.11 Built-in MMU table

ARM926EJS core requires memory management unit (MMU) to be initialized to make use of Data-cache and other memory protection functionality. For initializing MMU a translation table is required which defines section entries (Virtual to physical address mapping, cache enable, buffer enable, domain permission etc.). See ARM926EJS TRM for more details. The translation table has up to 4096 x 32-bit entries (total 16 kB of memory), each describing 1MB of virtual memory. This enables up to 4GB of virtual memory to be addressed. For systems which don't use any external memory (or systems which have tight memory requirement), LPC315x boot ROM provides a pre-defined MMU translation table in its ISROM. This translation table is available at location 0x1201 C000 in ISROM.

**Table 86. MMU translation table**

Virtual Address Range	Size in bytes	Entry Type	Physical Address	C	B	Other settings
0x00000000	1M	Section entry	0x00000000	0	0	Belongs to domain 0x0, cache disabled, write buffer disabled, and permission - User R/W, Supervisor R/W.

0x20200000 to 0x2FFFFFFF	254M	Section entries	0xFFF00000	0	0	Belongs to domain 0xF, cache disabled, buffer disabled, and permission - User no access, Supervisor R/W.
0x30000000 to 0x3FFFFFFF	256M	Section entries	0x30000000 to 0x3FFFFFFF	0	0	Belongs to domain 0x0, cache disabled, write buffer disabled, and permission - User R/W, Supervisor R/W.
0x40000000 to 0x4FFFFFFF	256M	Section entries	0x30000000 to 0x3FFFFFFF	1	1	Belongs to domain 0x0, cache enabled, write buffer enabled, and permission - User R/W, Supervisor R/W.
0x50000000 to 0x5FFFFFFF	256M	Section entries	0xFFF00000	0	0	Belongs to domain 0xF, cache disabled, buffer disabled, and permission - User no access, Supervisor R/W.
0x60000000	1M	Section entry	0x60000000	0	0	Belongs to domain 0x0, cache disabled, write buffer disabled, and permission - User R/W, Supervisor R/W.

Table 86. MMU translation table ...continued

Virtual Address Range	Size in bytes	Entry Type	Physical Address	C	B	Other settings
0x60100000 to 0x6FFFFFFF	255M	Section entries	0xFFF00000	0	0	Belongs to domain 0xF, cache disabled, buffer disabled, and permission - User no access, Supervisor R/W.
0x70000000	1M	Section entry	0x70000000	0	0	Belongs to domain 0x0, cache disabled, write buffer disabled, and permission - User R/W, Supervisor R/W.
0x70100000 to 0xFFFFFFFF	2303M	Section entries	0xFFF00000	0	0	Belongs to domain 0xF, cache disabled, buffer disabled, and permission - User no access, Supervisor R/W.

In the above table when,

C = 0, Cache is disabled for that section of virtual memory space.

C = 1, Cache is enabled for that section of virtual memory space.

B = 0, Write buffer is disabled for that section of virtual memory space.

B = 1, Write buffer is enabled for that section of virtual memory space.

## 5. Programming guide

### 5.1 Creating LPC315x bootable partition on SD/MMC cards using the 'fdisk' utility

This section gives the step-by-step instructions in creating LPC315x bootable partition on SD/MMC cards using "fdisk" utility available on Linux PC.

1. Invoke fdisk on the device node associated with SD card. Use 'dmesg' command to figure out "/dev/sdxx" device Linux used for the current USB card reader. The "/dev/sdxx" log entries appear at the very end of the dmesg output.

```
$ sudo fdisk /dev/sde
[sudo] password for xxx_user:
```

2. Print the current partition table entries.

```
Command (m for help): p
Disk /dev/sde: 32 MB, 32112640 bytes
1 heads, 62 sectors/track, 1011 cylinders
Units = cylinders of 62 * 512 = 31744 bytes
Disk identifier: 0xde283a86

   Device Boot      Start         End      Blocks   Id  System
/dev/sde1            2           899       27838    6   FAT16
/dev/sde2           900        1011        3472    df   BootIt
Command (m for help):
```

3. Note, always create "bootit" (partition type 0xDF) partition as second partition. So that when the card is plugged back into a Windows PC it doesn't format "bootit" partition. Windows will not complain as long as the first partition is either FAT or NTFS partition.
4. You could use 'm' command under "fdisk" to get help on other "fdisk" commands.

## 5. Delete all existing partitions on the card one at a time

```
Command (m for help): d
Partition number (1-4): 1
Command (m for help): d
Partition number (1-4): 2
```

## 6. Now create new partitions. To specify the amount of space you need to specify start block and end block for each partition. This is usually the cylinders numbers. Since they vary from card to card it is little confusing what to specify. So we create the second partition first with +1M (1 MB size).

```
Command (m for help): n
Command action
e   extended
p   primary partition (1-4)
p
Partition number (1-4): 2
First cylinder (1-1011, default 1):
Using default value 1
Last cylinder or +size or +sizeM or +sizeK (1-1011, default 1011): +1M
Command (m for help): t
Selected partition 2
Hex code (type L to list codes): df
Changed system type of partition 2 to df (BootIt)
Command (m for help):
```

## 7. Now create first partition of type FAT16 or FAT32. The card used in illustration is 32MB only so we will create FAT16 in this example.

```
Command (m for help): n
Command action
e   extended
p   primary partition (1-4)
p
Partition number (1-4): 1
First cylinder (34-1011, default 34):
Using default value 34
Last cylinder or +size or +sizeM or +sizeK (34-1011, default 1011):
Using default value 1011
Command (m for help): t
Partition number (1-4): 1
Hex code (type L to list codes): 6
Changed system type of partition 1 to 6 (FAT16)
Command (m for help): p
Disk /dev/sde: 32 MB, 32112640 bytes
1 heads, 62 sectors/track, 1011 cylinders
Units = cylinders of 62 * 512 = 31744 bytes
Disk identifier: 0xde283a86

Device Boot      Start         End      Blocks   Id  System
/dev/sde1            34          1011       30318    6  FAT16
/dev/sde2             1           33        1022+   df  BootIt

Partition table entries are not in disk order
Command (m for help):
```

## 8. Now write the table and exit from fdisk

```

Command (m for help): w
The partition table has been altered!
Calling ioctl() to re-read partition table.
WARNING: If you have created or modified any DOS 6.x
partitions, please see the fdisk manual page for additional
information.
Syncing disks.
$

```

9. Now dump the boot image to /dev/sde2 partition using "dd" command as follows. If you are using latest LPC315x CDL, the bin files generated by make system can be written directly to the card. If not then you need to create the image in the format described in [Section 6-4.2](#).

```

$ sudo dd if=./image.bin of=/dev/sde2 bs=512
[sudo] password for xxxuser:
102+1 records in
102+1 records out
52528 bytes (53 kB) copied, 0.186911 s, 281 kB/s
$

```

## 10. Now the card is ready for booting. Don't forget to "sync" the card before ejecting. Also don't forget to put LPC315x in SD/MMC boot mode.

## 5.2 CRC look-up table

LPC315x boot ROM has CRC32 lookup table to aid in faster computation of CRC32. Various CRC32 fields described in image formats used by boot ROM use this table which is accessible at location 0x12015CBC. The following C code gives an example on how to use this CRC table.

```

#define crc32table ((const u32*)0x12015CBC)
u32 crc32_compute(u8 *data, int length)
{
    u32 crc = 0xFFFFFFFF;
    while (length--)
    {
        crc = crc32table[(crc ^ *data++) & 0xFF] ^ (crc >> 8);
    }
    crc ^= 0xFFFFFFFF;
    return crc;
}

```

## 1. Introduction

The ISRAM controller is used as a memory controller between the AHB bus and the internal RAM memory. The internal RAM memory can be used as working memory for the ARM processor and as temporary storage to execute the code that is loaded by boot ROM from external devices such as SPI-flash, NAND flash, parallel NOR-flash and SD/MMC cards.

### 1.1 Feature list

- Full implementation of AHB protocol compliant to AMBA specification (Rev 2.0).
- Configurable latency (0, 1 or 2 AHB wait states) through SYSCREG\_ISRAM0\_LATENCY\_CFG (address 0x1300 2858, see [Table 27–552](#)) and SYSCREG\_ISRAM1\_LATENCY\_CFG (address 0x1300 285C, see [Table 27–553](#)) registers in SYSCREG
- Support bus endianness configuration through ARM926 coprocessor register setting.
- Single AHB slave interface towards multiple memory instances (ROM or SRAM).
- OR-bus compliant outputs.
- RAM capacity of 128 kB.
- Implemented as two memories of 96 kB. ISRAM0 starting at address 0x1102 8000 and ISRAM1 starting at address 0x1104 0000.

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock Signals

CGU will provides the clocks the ISRAM module (see [Table 7–87](#)).

Table 87. ISRAM module clock overview

Clock name	I/O	Source/destination	Max. Freq.	Description
ISROM0/1_CLK	I	CGU	75 MHz.	Main clock of the module. This clock is part of the AHB bus, and runs on the same clock as the AHB main clock.

#### 2.1.2 Reset signals

The CGU provides an asynchronous active-low reset (AHB\_RST\_N) which resets the logic in the ISRAM0/1\_CLK clock domain.

### 2.1.3 DMA transfers

The ISRAM module does not make use of flow control, but it is able to make use of DMA via the DMA module.

## 3. Register overview

---

The latency configuration signal is programmed by software through the SYSCREG\_ISRAM0/1\_LATENCY\_CFG registers in the SYSCREG block (see [Section 27–4.4](#)).

## 4. Functional description

---

The CPU can read or write data from or to the RAM via the ISRAM module. The CPU will address the ISRAM module, which will translate the incoming AHB address in a RAM address. Based on this address the RAM will provide the ISRAM module with data, which is stored on that address or will store data from the ISRAM module into the RAM. Then the ISRAM module will transport the data read from the RAM to the CPU, in case of a read operation, or transport data from the CPU to the RAM in case of a write operation.

By changing the latency through the memory controller less or more pipeline stages will be added. The more pipeline stages are used, the higher the frequency is which can be used, but the bigger the latency through the ISRAM module is.

## 5. Power optimization

---

This section describes the power optimization possibilities that are included in the ISRAM module.

- Internal power consumption is minimized by extensive use of enable signals, thus limiting the switching power dissipated. The user cannot influence this process.
- SRAM is designed to support the low power features of memory. According to the low power use of memory specifications, the address, data, WEB and BSEL inputs to memory remain still when no memory transfer is under progress. The user cannot influence this process.
- When the memory is not used the addresses remain as still as much as possible.
- When memory is inactive, keep the CL input activated (CL = H) to prevent any toggling on the address, DATA and BSEL inputs, from consuming any power within the RAM.
- The CS input should be inactive (CS = L) to prevent the memory from being activated and consuming any read or write power when clock is activated (CL transition L to H).
- The Write Enable (low-active) input should be placed in the read position (WEB = H) when the RAM is not selected as this will stop any transition on the DATA and BSEL inputs from consuming any power within the RAM.
- When the memory is not used the DATA and BSEL inputs should either remain stable as much as is possible or the memory should be placed in the read mode (WEB = H) or the memory should be placed in inactive mode with CL input activated (CL = H).

## 6. Programming guide

In total one value can be programmed, and two values are fixed by default. The latency through the ISRAM module can be programmed by software via register ISRAM\_LATENCY\_CFG (see [Table 27–552](#) and [Table 27–553](#)). [Table 7–88](#) gives an overview of possible latency settings.

**Table 88. ISRAM\_latency\_cfg.**

Value	Description
00	No latency (default in the LPC315x)
01	Insert 1 wait state
11	Insert 2 wait states

[Table 7–89](#) indicates which configuration settings can be done in the ISRAM module.

**Table 89. ISRAM configuration settings.**

Name	Description	Setting in this IC
bigend_a	0: set in little endianness mode 1: set in big endianness mode	Follows AHB0 big endianness setting. This signal is connected internally to CFGBIGEND signal coming out of ARM926 core. To change endianness user has to set endian bit (bit7) of control register c1 of ARM926EJ-S processor.
stall_req_a	0: normal mode 1: stall mode, operation is halted.	fixed to 0

## 1. Introduction

Universal Serial Bus (USB) is a standard protocol developed to connect several types of devices to each other in order to exchange data or for other purposes. Many portable devices can benefit from the ability to communicate to each other over the USB interface without intervention of a host PC. The addition of the On-The-Go functionality to USB makes this possible without losing the benefits of the standard USB protocol. Examples of USB devices are: PC, mouse, keyboard, MP3 player, digital camera, USB storage device (USB stick).

### 1.1 Features

- Complies with Universal Serial Bus specification 2.0.
- Complies with USB On-The-Go supplement.
- Complies with Enhanced Host Controller Interface Specification.
- Complies with AMBA specification.
- Supports auto USB 2.0 mode discovery.
- Supports all high-speed USB-compliant peripherals.
- Supports all full-speed USB-compliant peripherals.
- Supports all low-speed USB-compliant peripherals.
- Supports software HNP and SRP for OTG peripherals.
- Contains UTMI+ compliant transceiver (PHY).
- Supports power management.
- Supports four endpoints, control endpoint included.

### 1.2 About USB On-The-Go

The USB On-The-Go block enables usage in both device mode and in host mode. This means that you can connect to a PC to exchange data, but also to another USB device such as a digital camera or MP3 player.

The LPC315x boot ROM implements the Device Firmware Upgrade (DFU) class specification to download new applications into internal SRAM.

### 1.3 USB acronyms and abbreviations

Table 90. USB related acronyms

Acronym	Description
ATX	Analog Transceiver
DCD	Device Controller Driver
dQH	device Endpoint Queue Head
dTD	device Transfer Descriptor

**Table 90. USB related acronyms**

Acronym	Description
EOP	End Of Packet
EP	End Point
FS	Full Speed
HCD	Host Controller Driver
HS	High Speed
LS	Low Speed
MPS	Maximum Packet Size
NAK	Negative Acknowledge
OTG	On-The-Go
PID	Packet Identifier
QH	Queue Head
SE0	Single Ended 0
SOF	Start Of Frame
TT	Transaction Translator
USB	Universal Serial Bus

#### 1.4 Transmit and receive buffers

The USB OTG controller contains a Tx buffer to store data to be transmitted on the USB and an Rx buffer to store data received from the USB. The Rx buffer contains 256 words, and the Tx buffer contains 128 words for each endpoint in device mode and 512 words in host mode.

#### 1.5 Fixed endpoint configuration

[Table 8–91](#) shows the supported endpoint configurations. The Maximum Packet Size (MPS) (see [Table 8–92](#)) is dependent on the type of endpoint and the device configuration (low-speed, full-speed, or high-speed).

**Table 91. Fixed endpoint configuration**

Logical endpoint	Physical endpoint	Endpoint type	Direction
0	0	Control	Out
0	1	Control	In
1	2	Interrupt/Bulk/Isochronous	Out
1	3	Interrupt/Bulk/Isochronous	In
2	4	Interrupt/Bulk/Isochronous	Out
2	5	Interrupt/Bulk/Isochronous	In
3	6	Interrupt/Bulk/Isochronous	Out
3	7	Interrupt/Bulk/Isochronous	In

Table 92. USB Packet size

Endpoint type	Speed	Packet size (byte)
Control	Low-speed	8
	Full-speed	8, 16, 32, or 64
	High-speed	64
Isochronous	Low-speed	n/a
	Full-speed	up to 1023
	High-speed	up to 1024
Interrupt	Low-speed	up to 8
	Full-speed	up to 64
	High-speed	up to 1024
Bulk	Low-speed	n/a
	Full-speed	8, 16, 32, or 64
	High-speed	8, 16, 32, 64 or 512

## 2. General description

### 2.1 Block diagram

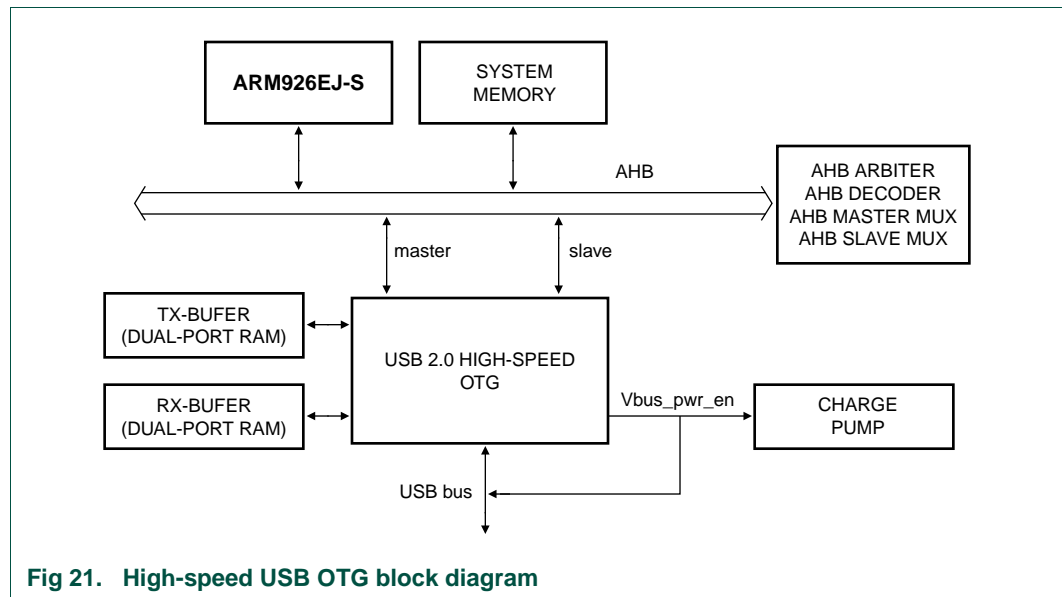

Fig 21. High-speed USB OTG block diagram

## 2.2 Interface description

### 2.2.1 Clock signals

Table 93. Clock signals of the USB-OTG

Clock name	I/O	Source/ destination	Description
USB_OTG_AHB_CLK	I	CGU	AHB bus clock. Minimum frequency is 53 MHz in order to meet the turn-around times.
USB_OTG_CLK	I	USB PLL	480 MHz main USB clock. This clock is generated by dedicated USB PLL present on chip. This PLL can be programmed through the SYSCREG block, see <a href="#">Section 27–4.3.1</a> .

### 2.2.2 Pin connections

Table 94. USB-OTG pin configuration

Name	Type	Description
USB_DP	IO	Positive USB line
USB_DM	IO	Negative USB line
USB_ID	I	Indicates to the USB transceiver whether in device (USB_ID HIGH) or host (USB_ID LOW) mode
USB_VBUS	I	USB power
USB_RREF	IO	Connected to external resistor for reference current
<b>Power and ground pins</b>		
USB_VDDA33_DRV		Analog power supply for driver
USB_VDDA33		Analog power supply (3.3 V) for PHY
USB_VSSA_TERM		Analog termination ground
USB_GNDA		Analog ground
USB_VSSA_REF		Analog reference ground

### 2.2.3 Interrupt requests

The USB controller has one configurable USB interrupt request line.

Pins USB\_VBUS and USB\_ID are external pins connected to the event router. In addition the following USB signals are connected to the event router: usb\_otg\_vbus\_pwr\_en, usb\_atx\_pll\_lock, usb\_otg\_ahb\_needclk (see [Table 17–353](#)).

### 2.2.4 Reset signals

The CGU provides one AHB domain reset signal to the USB register block.

## 3. Register overview

Table 95. Register access abbreviations

Abbreviation	Description
R/W	Read/Write
R/WC	Read/Write one to Clear

Table 95. Register access abbreviations

Abbreviation	Description
R/WO	Read/Write Once
RO	Read Only
WO	Write Only

Table 96. Register overview: USB OTG controller (register base address 0x1900 0000)

Name	Access	Address offset	Description
-	-	0x000 - 0x0FF	Reserved
<b>Device/host capability registers</b>			
CAPLENGTH	RO	0x100	Capability register length
HCIVERSION	RO	0x102	Host interface version number
HCSPARAMS	RO	0x104	Host controller structural parameters

ENDPTCTRL1	R/W	0x1C4	Endpoint control 1
ENDPTCTRL2	R/W	0x1C8	Endpoint control 2
ENDPTCTRL3	R/W	0x1CC	Endpoint control 3

### 3.1 Use of registers

The register interface has bit functions described for device mode and bit functions described for host mode. However, during OTG operations it is necessary to perform tasks independent of the controller mode.

The only way to transition the controller mode out of host or device mode is by setting the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independently of a controller reset as well as independently of the controller mode.

The following registers and register bits are used for OTG operations. The values of these register bits are independent of the controller mode and are not affected by a write to the RESET bit in the USBCMD register.

- All identification registers
- All device/host capabilities registers
- All bits of the OTGSC register ([Section 8–4.2.15](#))
- The following bits of the PORTSC register ([Section 8–4.2.14](#)):
  - PTS (parallel interface select)
  - STS (serial transceiver select)
  - PTW (parallel transceiver width)
  - PHCD (PHY low power suspend)
  - WKOC, WKDC, WKCN (wake signals)
  - PIC[1:0] (port indicators)
  - PP (port power)

## 4. Register description

### 4.1 Device/host capability registers

**Table 97. CAPLENGTH (address 0x1900 0100)**

Bit	Symbol	R/W	Reset value	Description
7:0	CAPLENGTH	RO	0x40	Indicates offset to add to the register base address at the beginning of the Operational Register

**Table 98. HCIVERSION (address 0x1900 0102)**

Bit	Symbol	R/W	Reset value	Description
15:0	HCIVERSION	RO	0x100	BCD encoding of the EHCI revision number supported by this host controller.

**Table 99. HCSPARAMS (address 0x1900 0104)**

Bit	Symbol	R/W	Reset value	Description
31:28	-	-	-	These bits are reserved and should be set to zero.
27:24	N_TT	RO	0x0	Number of Transaction Translators. This field indicates the number of embedded transaction translators associated with the USB2.0 host controller.
23:20	N_PTT	RO	0x0	Number of Ports per Transaction Translator. This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller.
19:17	-	-	-	These bits are reserved and should be set to zero.
16	PI	RO	0x1	Port indicators. This bit indicates whether the ports support port indicator control.
15:12	N_CC	RO	0x0	Number of Companion Controller. This field indicates the number of companion controllers associated with this USB2.0 host controller.
11:8	N_PCC	RO	0x0	Number of Ports per Companion Controller. This field indicates the number of ports supported per internal Companion Controller.
7:5	-	-	-	These bits are reserved and should be set to zero.
4	PPC	RO	0x1	Port Power Control. This field indicates whether the host controller implementation includes port power control.
3:0	N_PORTS	RO	0x1	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller.

**Table 100. HCCPARAMS (address 0x1900 0108)**

Bit	Symbol	R/W	Reset value	Description
31:9	-	-	-	These bits are reserved and should be set to zero.
15:8	EECP	RO	0	EHCI Extended Capabilities Pointer. This optional field indicates the existence of a capabilities list.
7:4	IST	RO	0	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule.
2	ASP	RO	1	Asynchronous Schedule Park Capability. If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register.
1	PFL	RO	1	Programmable Frame List Flag. If set to one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-boundary. This requirement ensures that the frame list is always physically contiguous.
0	ADC	RO	0	64-bit Addressing Capability. If zero, no 64-bit addressing capability is supported.

**Table 101. DCIVERSION (address 0x1900 0120)**

Bit	Symbol	R/W	Reset value	Description
15:0	DCIVERSION	RO	0x1	The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

**Table 102. DCCPARAMS (address 0x1900 0124)**

Bit	Symbol	R/W	Reset value	Description
31:9	-	-	-	These bits are reserved and should be set to zero.
8	HC	RO	0x1	Host Capable.
7	DC	RO	0x1	Device Capable.
6:5	-	-	-	These bits are reserved and should be set to zero.
4:0	DEN	RO	0x4	Device Endpoint Number.

## 4.2 Device/host operational registers

### 4.2.1 USB Command register (USBCMD)

The host/device controller executes the command indicated in this register.

#### 4.2.1.1 Device mode

Table 103. USB Command register (USBCMD - address 0x1900 0140) bit description - device mode

Bit	Symbol	Value	Description	Access	Reset value
0	RS		Run/Stop	R/W	0
		1	Writing a one to this bit will cause the device controller to enable a pull-up on USB_DP and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized.		
		0	Writing a 0 to this bit will cause a detach event.		
1	RST		Controller reset.	R/W	0
			Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.		
		1	When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial values. Writing a one to this bit when the device is in the attached state is not recommended, since the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.		
		0	Set to 0 by hardware when the reset process is complete.		
3:2	FS[1:0]	-	Not used in device mode.	-	0
4	PSE	-	Not used in device mode.	-	0
5	ASE	-	Not used in device mode.	-	0
6	IAA	-	Not used in device mode. Writing a one to this bit when the device mode is selected, will have undefined results.	-	-
7	-	-	Reserved. These bits should be set to 0.	-	-
9:8	ASP[1:0]	-	Not used in Device mode.	-	-
10	-	-	Reserved. These bits should be set to 0.	-	0
11	ASPE	-	Not used in Device mode.	-	-
12	-	-	Reserved. These bits should be set to 0.	-	0
13	SUTW		Setup trip wire	R/W	0
			During handling a setup packet, this bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (see USBMODE register) then there exists a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. (See <a href="#">Section 8-8</a> ).		

**Table 103. USB Command register (USBCMD - address 0x1900 0140) bit description - device mode ...continued**

Bit	Symbol	Value	Description	Access	Reset value
14	ATDTW		Add dTD trip wire  This bit is used as a semaphore to ensure the proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software during the process of adding a new dTD. See also <a href="#">Section 8-8</a> .  This bit shall also be cleared by hardware when its state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.	R/W	0
15	FS2		Not used in device mode.	-	-
23:16	ITC		Interrupt threshold control.  The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. All other values are reserved.	R/W	0x8
		0x0	Immediate (no threshold)		
		0x1	1 micro frame.		
		0x2	2 micro frames.		
		0x4	4 micro frames.		
		0x8	8 micro frames.		
		0x10	16 micro frames.		
		0x20	32 micro frames.		
		0x40	64 micro frames.		
31:24	-		Reserved		0

**4.2.1.2 Host mode**

**Table 104. USB Command register (USBCMD - address 0x1900 0140) bit description - host mode**

Bit	Symbol	Value	Description	Access	Reset value
0	RS		Run/Stop	R/W	0
		1	When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one.		
		0	When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one).		

Table 104. USB Command register (USBCMD - address 0x1900 0140) bit description - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
1	RST		Controller reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.	R/W	0
		1	When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior.		
		0	This bit is set to zero by hardware when the reset process is complete.		
2	FS0	see <a href="#">Table 8-105</a>	Bit 0 of the Frame List Size bits. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2.		0
3	FS1	see <a href="#">Table 8-105</a>	Bit 1 of the Frame List Size bits.		0
4	PSE		This bit controls whether the host controller skips processing the periodic schedule.	R/W	0
		1	Use the PERIODICLISTBASE register to access the periodic schedule.		
		0	Do not process the periodic schedule.		
5	ASE		This bit controls whether the host controller skips processing the asynchronous schedule.	R/W	0
		1	Use the ASYNCLISTADDR to access the asynchronous schedule.		
		0	Do not process the asynchronous schedule.		
6	IAA		This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule.	R/W	0
		1	Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results.		
		0	The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one.		
7	-	-	Reserved		0
8:9	ASP[1:0]		Asynchronous schedule park mode	R/W	11

**Table 104. USB Command register (USBCMD - address 0x1900 0140) bit description - host mode ...continued**

Bit	Symbol	Value	Description	Access	Reset value
		00, 01, 10, 11	Contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 0x1 to 0x3.  <b>Remark:</b> Software must not write 00 to this bit when Park Mode Enable is one as this will result in undefined behavior.		
10	-	-	Reserved.	-	0
11	ASPE		Asynchronous Schedule Park Mode Enable	R/W	1
		1	Park mode is enabled.		
		0	Park mode is disabled.		
12	-	-	Not used in Host mode.	-	0
13	-	-	Not used in Host mode.	-	
14	-	-	Reserved.	-	0
15	FS2	see <a href="#">Table 8-105</a>	Bit 2 of the Frame List Size bits.	-	0
23:16	ITC		Interrupt threshold control.  The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. All other values are reserved.	R/W	0x8
		0x0	Immediate (no threshold)		
		0x1	1 micro frame.		
		0x2	2 micro frames.		
		0x4	4 micro frames.		
		0x8	8 micro frames.		
		0x10	16 micro frames.		
		0x20	32 micro frames.		
		0x40	64 micro frames.		
31:24	-		Reserved		0

**Table 105. Frame list size values**

USBCMD bit 15	USBCMD bit 3	USBCMD bit 2	Frame list size
0	0	0	1024 elements (4096 bytes) - default value
0	0	1	512 elements (2048 bytes)
0	1	0	256 elements (1024 bytes)
0	1	1	128 elements (512 bytes)
1	0	0	64 elements (256 bytes)
1	0	1	32 elements (128 bytes)
1	1	0	16 elements (64 bytes)
1	1	1	8 elements (32 bytes)

## 4.2.2 USB Status register (USBSTS)

This register indicates various states of the Host/Device controller and any pending interrupts. Software sets a bit to zero in this register by writing a one to it.

**Remark:** This register does not indicate status resulting from a transaction on the serial bus.

### 4.2.2.1 Device mode

**Table 106. USB Status register (USBSTS - address 0x1900 0144) register bit description - device mode**

Bit	Symbol	Value	Description	Access	Reset value
0	UI		USB interrupt	R/WC	0
		1	This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.  This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.		
		0	This bit is cleared by software writing a one to it.		
1	UEI		USB error interrupt	R/WC	0
		1	When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only (see <a href="#">Section 8–8.11.6</a> ).		
		0	This bit is cleared by software writing a one to it.		
2	PCI		Port change detect.	R/WC	0
		1	The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit (URI) and the DCSuspend bits (SLI) respectively.		
		0	This bit is cleared by software writing a one to it.		
3	FRI		Not used in Device mode.		
4	-	0	Reserved.		
5	AAI		Not used in Device mode.	-	0
6	URI		USB reset received	R/WC	0
		1	When the device controller detects a USB Reset and enters the default state, this bit will be set to a one.		
		0	This bit is cleared by software writing a one to it.		

Table 106. USB Status register (USBSTS - address 0x1900 0144) register bit description - device mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
7	SRI		SOF received	R/WC	0
		1	When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1 ms in device FS mode and every 125 $\mu$ s in HS mode and will be synchronized to the actual SOF that is received. Since the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.		
8	SLI	0	This bit is cleared by software writing a one to it.	R/WC	0
		1	When a device controller enters a suspend state from an active state, this bit will be set to a one.		
		0	The device controller clears the bit upon exiting from a suspend state. This bit is cleared by software writing a one to it.		
11:9	-	-	Reserved. Software should only write 0 to reserved bits.		
12	HCH	-	Not used in Device mode.		0
13	RCL	-	Not used in Device mode.		0
14	PS	-	Not used in Device mode.		0
15	AS	-	Not used in Device mode.		0
16	NAKI		NAK interrupt bit	RO	0
		1	It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set.		
		0	This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared.		
17	-	-	Reserved. Software should only write 0 to reserved bits.	-	0
18	UAI		Not used in Device mode.	-	0
19	UPI		Not used in Device mode.	-	0
31:20	-	-	Reserved. Software should only write 0 to reserved bits.	-	

## 4.2.2.2 Host mode

Table 107. USB Status register (USBSTS - address 0x1900 0144) register bit description - host mode

Bit	Symbol	Value	Description	Access	Reset value
0	UI		USB interrupt (USBINT)	R/WC	0
		1	This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.  This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.		
		0	This bit is cleared by software writing a one to it.		
1	UEI		USB error interrupt (USBERRINT)	R/WC	0
		1	When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.		
		0	This bit is cleared by software writing a one to it.		
2	PCI		Port change detect.	R/WC	0
		1	The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.		
		0	This bit is cleared by software writing a one to it.		
3	FRI		Frame list roll-over	R/WC	0
		1	The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FRINDEX [12] toggles (see <a href="#">Section 8-4.2.4</a> ).		
		0	This bit is cleared by software writing a one to it.		
4	-	0	Reserved.		
5	AAI		Interrupt on async advance	R/WC	0
		1	System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source.		
		0	This bit is cleared by software writing a one to it.		
6	URI	-	Not used by the Host controller.	R/WC	0
7	SRI		SOF received	R/WC	0
		1	In host mode, this bit will be set every 125 $\mu$ s and can be used by host controller driver as a time base.		
		0	This bit is cleared by software writing a one to it.		
8	SLI	-	Not used by the Host controller.	-	-
11:9	-	-	Reserved.		

Table 107. USB Status register (USBSTS - address 0x1900 0144) register bit description - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
12	HCH		HCHalted	RO	1
		1	The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. because of an internal error).		
		0	The RS bit in USBCMD is set to zero. Set by the host controller.		
13	RCL		Reclamation	RO	0
		1	An empty asynchronous schedule is detected. Set by the host controller.		
		0	No empty asynchronous schedule detected.		
14	PS		Periodic schedule status	RO	0
			This bit reports the current real status of the Periodic Schedule. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (if both are 1) or disabled (if both are 0).		
		1	The periodic schedule status is enabled.		
		0	The periodic schedule status is disabled.		
15	AS		Asynchronous schedule status		0
			This bit reports the current real status of the Asynchronous Schedule. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (if both are 1) or disabled (if both are 0).		
		1	Asynchronous schedule status is enabled.		
		0	Asynchronous schedule status is disabled.		
16	NAKI		Not used on Host mode.	-	0
17	-		Reserved.		
18	UAI		USB host asynchronous interrupt (USBHSTASYNCINT)	R/WC	0
		1	This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set <b>and</b> the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected <b>and</b> the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes.		
		0	This bit is cleared by software writing a one to it.		
19	UPI		USB host periodic interrupt (USBHSTPERINT)	R/WC	0
		1	This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set <b>and</b> the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected <b>and</b> the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes.		
		0	This bit is cleared by software writing a one to it.		

31:20 -

### 4.2.3 USB Interrupt register (USBINTR)

The software interrupts are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt is active. The USB Status register (USBSTS) still shows interrupt sources even if they are disabled by the USBINTR register, allowing polling of interrupt events by the software. All interrupts must be acknowledged by software by clearing (that is writing a 1 to) the corresponding bit in the USBSTS register.

#### 4.2.3.1 Device mode

**Table 108. USB Interrupt register (USBINTR - address 0x1900 0148) bit description - device mode**

Bit	Symbol	Description	Access	Reset value
0	UE	USB interrupt enable When this bit is one, and the USBINT bit in the USBSTS register is one, the host/device controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBINT bit in USBSTS.	R/W	0
1	UEE	USB error interrupt enable When this bit is a one, and the USBERRINT bit in the USBSTS register is a one, the host/device controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register.	R/W	0
2	PCE	Port change detect enable When this bit is a one, and the Port Change Detect bit in the USBSTS register is a one, the host/device controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port Change Detect bit in USBSTS.	R/W	0
3	FRE	Not used by the Device controller.		
4	-	Reserved	-	0
5	AAE	Not used by the Device controller.		
6	URE	USB reset enable When this bit is a one, and the USB Reset Received bit in the USBSTS register is a one, the device controller will issue an interrupt. The interrupt is acknowledged by software clearing the USB Reset Received bit.	R/W	0
7	SRE	SOF received enable When this bit is a one, and the SOF Received bit in the USBSTS register is a one, the device controller will issue an interrupt. The interrupt is acknowledged by software clearing the SOF Received bit.	R/W	0
8	SLE	Sleep enable When this bit is a one, and the DCSuspend bit in the USBSTS register transitions, the device controller will issue an interrupt. The interrupt is acknowledged by software writing a one to the DCSuspend bit.	R/W	0
15:9	-	Reserved	-	-
16	NAKE	NAK interrupt enable This bit is set by software if it wants to enable the hardware interrupt for the NAK Interrupt bit. If both this bit and the corresponding NAK Interrupt bit are set, a hardware interrupt is generated.	R/W	0
17	-	Reserved		
18	UAIE	Not used by the Device controller.		
19	UPIA	Not used by the Device controller.		
31:20	-	Reserved		

## 4.2.3.2 Host mode

Table 109. USB Interrupt register (USBINTR - address 0x1900 0148) bit description - host mode

Bit	Symbol	Description	Access	Reset value
0	UE	USB interrupt enable When this bit is one, and the USBINT bit in the USBSTS register is one, the host/device controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBINT bit in USBSTS.	R/W	0
1	UEE	USB error interrupt enable When this bit is a one, and the USBERRINT bit in the USBSTS register is a one, the host/device controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register.	R/W	0
2	PCE	Port change detect enable When this bit is a one, and the Port Change Detect bit in the USBSTS register is a one, the host/device controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port Change Detect bit in USBSTS.	R/W	0
3	FRE	Frame list rollover enable When this bit is a one, and the Frame List Rollover bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Frame List Rollover bit.		
4	-	Reserved	-	0
5	AAE	Interrupt on asynchronous advance enable When this bit is a one, and the Interrupt on Async Advance bit in the USBSTS register is a one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit.	R/W	0
6	-	Not used by the Host controller.	-	0
7	SRE	If this bit is one and the SRI bit in the USBSTS register is one, the host controller will issue an interrupt. In host mode, the SRI bit will be set every 125 $\mu$ s and can be used by the host controller as a time base. The interrupt is acknowledged by software clearing the SRI bit in the USBSTS register.	-	0
8	SLE	Not used by the Host controller.	-	0
15:9	-	Reserved		
16	NAKE	Not used by the host controller.	R/W	0
17	-	Reserved		
18	UAIE	USB host asynchronous interrupt enable When this bit is a one, and the USBHSTASYNCINT bit in the USBSTS register is a one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBHSTASYNCINT bit.	R/W	0
19	UPIA	USB host periodic interrupt enable When this bit is a one, and the USBHSTPERINT bit in the USBSTS register is a one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBHSTPERINT bit.	R/W	0
31:20	-	Reserved		

### 4.2.4 Frame index register (FRINDEX)

#### 4.2.4.1 Device mode

In Device mode this register is read only, and the device controller updates the FRINDEX[13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX[13:3] will be checked against the SOF marker. If FRINDEX[13:3] is different from the SOF marker, FRINDEX[13:3] will be set to the SOF value and FRINDEX[2:0] will be set to zero (i.e. SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX[2:0] will be incremented (i.e. SOF for 125 μs micro-frame) by hardware.

**Table 110. USB frame index register (FRINDEX - address 0x1900 014C) bit description - device mode**

Bit	Symbol	Description	Access	Reset value
2:0	FRINDEX[2:0]	Current micro frame number	RO	N/A
13:3	FRINDEX[13:3]	Current frame number of the last frame transmitted	RO	N/A
31:14	-	Reserved		N/A

#### 4.2.4.2 Host mode

This register is used by the host controller to index the periodic frame list. The register updates every 125 μs (once each micro-frame). Bits[N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit in the USBSTS register (host mode). A write to this register while the Run/Stop bit is set to a one produces undefined results. Writes to this register also affect the SOF value.

**Table 111. USB frame index register (FRINDEX - address 0x1900 014C) bit description - host mode**

Bit	Symbol	Description	Access	Reset value
2:0	FRINDEX[2:0]	Current micro frame number	R/W	N/A
N:3	FRINDEX[N:3]	Frame list current index	R/W	N/A
31:(N+1)	-	Reserved		N/A

**Table 112. Number of bits used for the frame list index**

USBCMD bit 15	USBCMD bit 3	USBCMD bit 2	Frame list size	N
0	0	0	1024 elements (4096 bytes). Default value.	12
0	0	1	512 elements (2048 bytes)	11
0	1	0	256 elements (1024 bytes)	10
0	1	1	128 elements (512 bytes)	9
1	0	0	64 elements (256 bytes)	8

Table 112. Number of bits used for the frame list index

USBCMD bit 15	USBCMD bit 3	USBCMD bit 2	Frame list size	N
1	0	1	32 elements (128 bytes)	7
1	1	0	16 elements (64 bytes)	6
1	1	1	8 elements (32 bytes)	5

### 4.2.5 Device address (DEVICEADDR - device) and Periodic List Base (PERIODICLISTBASE- host) registers

#### 4.2.5.1 Device mode

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET\_ADDRESS descriptor.

The USBADRA bit is used to accelerate the SET\_ADDRESS sequence by allowing the DCD to preset the USBADR register bits before the status phase of the SET\_ADDRESS descriptor.

Table 113. USB Device Address register (DEVICEADDR - address 0x1900 0154) bit description - device mode

Bit	Symbol	Value	Description	Access	Reset value
23:0	-		reserved	-	0
24	USBADRA	1	<p>Device address advance</p> <p>When the user writes a one to this bit at the same time or before USBADR is written, the write to USBADR fields is staged and held in a hidden register. After an IN occurs on endpoint 0 and is acknowledged, USBADR will be loaded from the holding register.</p> <p>Hardware will automatically clear this bit on the following conditions:</p> <ul style="list-style-type: none"> <li>• IN is ACKed to endpoint 0. USBADR is updated from the staging register.</li> <li>• OUT/SETUP occurs on endpoint 0. USBADR is <b>not</b> updated.</li> <li>• Device reset occurs. USBADR is set to 0.</li> </ul> <p><b>Remark:</b> After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2 ms USB requirement.</p>		
		0	Any write to USBADR are instantaneous.		
31:25	USBADR		USB device address	R/W	0

#### 4.2.5.2 Host mode

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. The host controller driver (HCD) loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4 kb aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Table 114. USB Periodic List Base register (PERIODICLISTBASE - address 0x1900 0154) bit description - host mode

Bit	Symbol	Description	Access	Reset value
11:0	-	reserved	-	N/A
31:12	PERBASE[31:12]	Base Address (Low) These bits correspond to the memory address signals[31:12].	R/W	N/A

## 4.2.6 Endpoint List Address register (ENDPOINTLISTADDR - device) and Asynchronous List Address (ASYNCLISTADDR - host) registers

### 4.2.6.1 Device mode

In device mode, this register contains the address of the top of the endpoint list in system memory. Bits[10:0] of this register cannot be modified by the system software and will always return a zero when read. The memory structure referenced by this physical memory pointer is assumed 64 byte aligned.

Table 115. USB Endpoint List Address register (ENDPOINTLISTADDR - address 0x1900 0158) bit description - device mode

Bit	Symbol	Description	Access	Reset value
10:0	-	reserved	-	0
31:11	EPBASE[31:11]	Endpoint list pointer (low) These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 4 Queue Heads (QH). (i.e. one queue head per endpoint and direction.)	R/W	N/A

### 4.2.6.2 Host mode

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Table 116. USB Asynchronous List Address register (ASYNCLISTADDR - address 0x1900 0158) bit description - host mode

Bit	Symbol	Description	Access	Reset value
4:0	-	Reserved	-	0
31:5	ASYBASE[31:5]	Link pointer (Low) LPL These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH).	R/W	N/A

## 4.2.7 TT Control register (TTCTRL)

### 4.2.7.1 Device mode

This register is not used in device mode.

### 4.2.7.2 Host mode

This register contains parameters needed for internal TT operations. This register is used by the host controller only. Writes must be in Dwords.

Table 117. USB TT Control register (TTCTRL - address 0x1900 015C) bit description - host mode

Bit	Symbol	Description	Access	Reset value
23:0	-	Reserved.	-	0
30:24	TTHA	Hub address when FS or LS device are connected directly.	R/W	N/A
31	-	Reserved.		0

#### 4.2.8 Burst Size register (BURSTSIZE)

This register is used to control and dynamically change the burst size used during data movement on the master interface of the USB DMA controller. Writes must be in Dwords.

The default for the length of a burst of 32-bit words for RX and TX DMA data transfers is 16 words each.

Table 118. USB burst size register (BURSTSIZE - address 0x1900 0160) bit description - device/host mode

Bit	Symbol	Description	Access	Reset value
7:0	RXPBURST	Programmable RX burst length This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.	R/W	0x10
15:8	TXPBURST	Programmable TX burst length This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.	R/W	0x10
31:16	-	reserved	-	-

#### 4.2.9 Transfer buffer Fill Tuning register (TXFILLTUNING)

##### 4.2.9.1 Device controller

This register is not used in device mode.

##### 4.2.9.2 Host controller

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

$T_0$  = Standard packet overhead

$T_1$  = Time to send data payload

$T_{ff}$  = Time to fetch packet into TX FIFO up to specified level

$T_s$  = Total packet flight time (send-only) packet;  $T_s = T_0 + T_1$

$T_p$  = Total packet time (fetch and send) packet;  $T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure  $T_p$  remains before the end of the (micro) frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is  $< T_s$  then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "backoff"

event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Backoffs can be minimized with use of the TSCHEALTH ( $T_{ff}$ ) described below.

**Table 119. USB Transfer buffer Fill Tuning register (TXFIFOFILLTUNING - address 0x1900 0164) bit description - host mode**

Bit	Symbol	Description	Access	Reset value
7:0	TXSCHOH	FIFO burst threshold  This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.	R/W	0x2
12:8	TXSCHEALTH	Scheduler health counter  This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame.  This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter. The maximum value is 31.	R/W	0x0
15:13	-	reserved	-	-
21:16	TXFIFOTHRES	Scheduler overhead  This register adds an additional fixed offset to the schedule time estimator described above as $T_{ff}$ . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization.  The time unit represented in this register is 1.267 $\mu$ s when a device is connected in High-Speed Mode for OTG and SPH.  The time unit represented in this register is 6.333 $\mu$ s when a device is connected in Low/Full Speed Mode for OTG and SPH.	R/W	0x0
31:22	-	reserved	-	-

#### 4.2.10 BINTERVAL register

This register defines the bInterval value which determines the length of the virtual frame (see [Section 8-5.7](#)).

**Table 120. USB BINTERVAL register (BINTERVAL - address 0x1900 0174) bit description - device/host mode**

Bit	Symbol	Description	Access	Reset value
3:0	BINT	bInterval value (see <a href="#">Section 8-5.7</a> )	R/W	0x00
31:4	-	reserved	-	-

**4.2.11 USB Endpoint NAK register (ENDPTNAK)**

**4.2.11.1 Device mode**

This register indicates when the device sends a NAK handshake on an endpoint. Each Tx and Rx endpoint has a bit in the EPTN and EPRN field respectively.

A bit in this register is cleared by writing a 1 to it.

**Table 121. USB endpoint NAK register (ENDPTNAK - address 0x1900 0178) bit description - device mode**

Bit	Symbol	Description	Access	Reset value
3:0	EPRN[3:0]	Rx endpoint NAK Each RX endpoint has one bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. Bit 3 corresponds to endpoint 3. ... Bit 1 corresponds to endpoint 1. Bit 0 corresponds to endpoint 0.	R/WC	0x00
15:4	-	reserved	-	-
19:16	EPTN[3:0]	Tx endpoint NAK Each TX endpoint has one bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. Bit 3 corresponds to endpoint 3. ... Bit 1 corresponds to endpoint 1. Bit 0 corresponds to endpoint 0.	R/WC	0x00
31:20	-	reserved	-	-

**4.2.11.2 Host mode**

This register is not used in host mode.

**4.2.12 USB Endpoint NAK Enable register (ENDPTNAKEN)**

**4.2.12.1 Device mode**

Each bit in this register enables the corresponding bit in the ENDPTNAK register. Each Tx and Rx endpoint has a bit in the EPTNE and EPRNE field respectively.

**Table 122. USB Endpoint NAK Enable register (ENDPTNAKEN - address 0x1900 017C) bit description - device mode**

Bit	Symbol	Description	Access	Reset value
3:0	EPRNE[3:0]	Rx endpoint NAK enable Each bit enables the corresponding RX NAK bit. If this bit is set and the corresponding RX endpoint NAK bit is set, the NAK interrupt bit is set. Bit 3 corresponds to endpoint 3. ... Bit 1 corresponds to endpoint 1. Bit 0 corresponds to endpoint 0.	R/W	0x00
15:4	-	reserved	-	-
19:16	EPTNE[3:0]	Tx endpoint NAK Each bit enables the corresponding TX NAK bit. If this bit is set and the corresponding TX endpoint NAK bit is set, the NAK interrupt bit is set. Bit 3 corresponds to endpoint 3. ... Bit 1 corresponds to endpoint 1. Bit 0 corresponds to endpoint 0.	R/W	0x00
31:20	-	reserved	-	-

**4.2.12.2 Host mode**

This register is not used in host mode.

**4.2.13 CONFIGFLAG register**

This register is not used on the LPC315x.

**Table 123. CONFIGFLAG (address 0x1900 0180) bit description**

Bit	Symbol	R/W	Reset value	Description
31:0	CONFIGFLAG	R	0x1	Not used in this implementation

**4.2.14 Port Status and Control register (PORTSC1)**

**4.2.14.1 Device mode**

The device controller implements one port register, and it does not support power control. Port control in device mode is used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling. This register allows software to put the PHY into low-power Suspend mode and disable the PHY clock.

Table 124. Port Status and Control register (PRTSC1 - address 0x1900 0184) bit description - device mode

Bit	Symbol	Value	Description	Access	Reset value
0	CCS		Current connect status	RO	0
		1	Device attached. A one indicates that the device successfully attached and is operating in either high-speed mode or full-speed mode as indicated by the High Speed Port bit in this register.		
		0	Device not attached A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.		
1	CSC	-	Not used in device mode	-	0
2	PE	1	Port enable. This bit is always 1. The device port is always enabled.	RO	1
3	PEC	0	Port enable/disable change This bit is always 0. The device port is always enabled.	RO	0
5:4	-	-	Reserved	RO	0
6	FPR		Force port resume After the device has been in Suspend State for 5 ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. When this bit transitions to a one because a J-to-K transition detected, the Port Change Detect bit in the USBSTS register is set to one as well.	R/W	0
		1	Resume detected/driven on port.		
		0	No resume (K-state) detected/driven on port.		
7	SUSP		Suspend In device mode, this is a read-only status bit .	RO	0
		1	Port in suspend state		
		0	Port not in suspend state		
8	PR		Port reset In device mode, this is a read-only status bit. A device reset from the USB bus is also indicated in the USBSTS register.	RO	0
		1	Port is in the reset state.		
		0	Port is not in the reset state.		
9	HSP		High-speed status <b>Remark:</b> This bit is redundant with bits [27:26] (PSPD) in this register. It is implemented for compatibility reasons.	RO	0
		1	Host/device connected to the port is in High-speed mode.		
		0	Host/device connected to the port is not in High-speed mode.		
11:10	LS	-	Not used in device mode.		
12	PP	-	Not used in device mode.		
13	-	-	Reserved	-	-

Table 124. Port Status and Control register (PRTSC1 - address 0x1900 0184) bit description - device mode

Bit	Symbol	Value	Description	Access	Reset value
15:14	PIC[1:0]		Port indicator control Writing to this field effects the value of the USB_OTG_PORT_IND_CTL register (see <a href="#">Table 27–545</a> ).	R/W	00
		00	Port indicators are off.		
		01	amber		
		10	green		
		11	undefined		
19:16	PTC[3:0]		Port test control Any value other than 0000 indicates that the port is operating in test mode. The FORCE_ENABLE_FS and FORCE_ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_HS/FS/LS values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point.	R/W	0000
		0000	TEST_MODE_DISABLE		
		0001	J_STATE		
		0010	K_STATE		
		0011	SE0 (host)/NAK (device)		
		0100	Packet		
		0101	FORCE_ENABLE_HS		
		0110	FORCE_ENABLE_FS		
		0111	invalid in device mode.		
		1000 to 1111	Reserved		
20	WKCN	-	Not used in device mode. This bit is always 0 in device mode.	-	0
21	WKDC	-	Not used in device mode. This bit is always 0 in device mode.	-	0
22	WKOC	-	Not used in device mode. This bit is always 0 in device mode.	-	0
23	PHCD		PHY low power suspend - clock disable (PLPSCD) In device mode, The PHY can be put into Low Power Suspend – Clock Disable when the device is not running (USBCMD Run/Stop = 0) or the host has signaled suspend (PORTSC SUSPEND = 1). Low power suspend will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the device controller driver must clear this bit.	R/W	0
		1	Writing a 1 disables the PHY clock. Reading a 1 indicates the status of the PHY clock (disabled).		
		0	Writing a 0 enables the PHY clock. Reading a 0 indicates the status of the PHY clock (enabled).		
24	PFSC		Port force full speed connect	R/W	0
		1	Writing this bit to a 1 will force the port to only connect at full speed. It disables the chirp sequence that allows the port to identify itself as High-speed. This is useful for testing FS configurations with a HS host, hub or device.		
		0	Port connects at any speed.		

**Table 124. Port Status and Control register (PRTSC1 - address 0x1900 0184) bit description - device mode**

Bit	Symbol	Value	Description	Access	Reset value
25	-	-	reserved		
27:26	PSPD		Port speed This register field indicates the speed at which the port is operating.	RO	0
		00	Full-speed		
		01	invalid in device mode		
		10	High-speed		
31:28	-	-	Reserved	-	-

**4.2.14.2 Host mode**

The host controller uses one port. The register is only reset when power is initially applied or in response to a controller reset. The initial conditions of the port are:

- No device connected
- Port disabled

If the port has power control, this state remains until software applies power to the port by setting port power to one in the PORTSC register.

**Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode**

Bit	Symbol	Value	Description	Access	Reset value
0	CCS		Current connect status This value reflects the current state of the port and may not correspond directly to the event that caused the CSC bit to be set. This bit is 0 if PP (Port Power bit) is 0. Software clears this bit by writing a 1 to it.	R/WC	0
		1	Device is present on the port.		
		0	No device is present.		
1	CSC		Connect status change Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This bit is 0 if PP (Port Power bit) is 0	R/WC	0
		1	Change in current status.		
		0	No change in current status.		

Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
2	PE	1	Port enable.  Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events.  When the port is disabled, downstream propagation of data is blocked except for reset.  This bit is 0 if PP (Port Power bit) is 0.	R/W	0
		1	Port enabled.		
		0	Port disabled.		
3	PEC	0	Port disable/enable change  For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See <i>Chapter 11 of the USB Specification</i> ). Software clears this by writing a one to it.  This bit is 0 if PP (Port Power bit) is 0,	R/WC	0
		1	Port enabled/disabled status has changed.		
		0	No change.		
4	OCA		Over-current active  This bit will automatically transition from 1 to 0 when the over-current condition is removed. This bit gets set when the usb_otg_vbus_pwr_fault (bit 3) in USB_OTG_CFG is set (see <a href="#">Table 27-544</a> ). Software should monitor OC condition on an unused GPIO pin and set USB_OTG_CFG register, so that the standard EHCI driver can use this bit.	RO	0
		1	The port has currently an over-current condition.		
		0	The port does not have an over-current condition.		
5	OCC		Over-current change  This bit gets set to one when there is a change to Over-current Active. Software clears this bit by writing a one to this bit position.	R/WC	0

Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
6	FPR		Force port resume	R/W	0
			Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.		
			Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation clear the bit the port control state switches to HS or FS idle. This bit is 0 if PP (Port Power bit) is 0.		
	1	Resume detected/driven on port.			
	0	No resume (K-state) detected/driven on port.			
7	SUSP		Suspend	R/W	0
			Together with the PE (Port enabled bit), this bit describes the port states, see <a href="#">Table 8–126 “Port states as described by the PE and SUSP bits in the PORTSC1 register”</a> .		
			The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. This bit is 0 if PP (Port Power bit) is 0.		
	1	Port in suspend state			
		When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB.			
	0	Port not in suspend state			
8	PR		Port reset	R/W	0
			When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. This bit is 0 if PP (Port Power bit) is 0.		
			1		
	0	Port is not in the reset state.			

Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
9	HSP		High-speed status	RO	0
		1	Host/device connected to the port is in High-speed mode.		
		0	Host/device connected to the port is not in High-speed mode.		
11:10	LS		Line status	RO	0x3
			These bits reflect the current logical levels of the USB_DP and USB_DM signal lines. USB_DP corresponds to bit 11 and USB_DM to bit 10. In host mode, the use of linestate by the host controller driver is not necessary for this controller (unlike EHCI) because the controller hardware manages the connection of LS and FS.		
		00	SE0 (USB_DP and USB_DM LOW)		
		10	J-state (USB_DP HIGH and USB_DM LOW)		
		01	K-state (USB_DP LOW and USB_DM HIGH)		
		11	Undefined		
12	PP	-	Port power control	R/W	0
			Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e. PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port).		
		1	Port power on.		
		0	Port power off.		
13	-	-	Reserved	-	0
15:14	PIC[1:0]		Port indicator control	R/W	00
			Writing to this field effects the value of the USB_OTG_PORT_IND_CTL register (see <a href="#">Table 27-545</a> ).		
		00	Port indicators are off.		
		01	Amber		
		10	Green		
		11	Undefined		

Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
19:16	PTC[3:0]		Port test control Any value other than 0000 indicates that the port is operating in test mode.  The FORCE_ENABLE_FS and FORCE_ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point.	R/W	0000
		0000	TEST_MODE_DISABLE		
		0001	J_STATE		
		0010	K_STATE		
		0011	SE0 (host)/NAK (device)		
		0100	Packet		
		0101	FORCE_ENABLE_HS		
		0110	FORCE_ENABLE_FS		
		0111	FORCE_ENABLE_LS		
		1000 to 1111	reserved		
20	WKCN		Wake on connect enable (WKCNT_E) This bit is 0 if PP (Port Power bit) is 0	R/W	0
		1	Writing this bit to a one enables the port to be sensitive to device connects as wake-up events.		
		0	Disables the port to wake up on device connects.		
21	WKDC		Wake on disconnect enable (WKDSCNT_E) This bit is 0 if PP (Port Power bit) is 0.	R/W	0
		1	Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events.		
		0	Disables the port to wake up on device disconnects.		
22	WKOC		Wake on over-current enable (WKOC_E)	R/W	0
		1	Writing a one to this bit enabled the port to be sensitive to over-current conditions as wake-up events.		
		0	Disables the port to wake up on over-current events.		
23	PHCD		PHY low power suspend - clock disable (PLPSCD) In host mode, the PHY can be put into Low Power Suspend – Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software.	R/W	0
		1	Writing a 1 disables the PHY clock. Reading a 1 indicates the status of the PHY clock (disabled).		
		0	Writing a 0 enables the PHY clock. Reading a 0 indicates the status of the PHY clock (enabled).		

**Table 125. Port Status and Control register (PRTSC1 - address 0x1900 0184) - host mode ...continued**

Bit	Symbol	Value	Description	Access	Reset value
24	PFSC		Port force full speed connect	R/W	0
		1	Writing this bit to a 1 will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device.		
		0	Port connects at any speed.		
25	-	-	reserved		
27:26	PSPD		Port speed	RO	0
			This register field indicates the speed at which the port is operating. For HS mode operation in the host controller and HS/FS operation in the device controller the port routing steers data to the Protocol engine. For FS and LS mode operation in the host controller, the port routing steers data to the Protocol Engine w/ Embedded Transaction Translator.		
		00	Full-speed		
		01	Low-speed

PE bit	SUSP bit	Port state
0	0 or 1	disabled
1	0	enabled
1	1	suspend

#### 4.2.15 OTG Status and Control register (OTGSC)

The OTG register has four sections:

- OTG interrupt enables (R/W)
- OTG Interrupt status (R/WC)
- OTG status inputs (RO)
- OTG controls (R/W)

The status inputs are debounced using a 1 msec time constant. Values on the status inputs that do not persist for more than 1 msec will not cause an update of the status input register or cause an OTG interrupt.

**Table 127. OTG Status and Control register (OTGSC - address 0x1900 01A4) bit description**

Bit	Symbol	Value	Description	Access	Reset value
<b>OTG controls</b>					
0	VD		VBUS_Discharge Setting this bit to 1 causes VBUS to discharge through a resistor.	R/W	0
1	VC		VBUS_Charge Setting this bit to 1 causes the VBUS line to be charged. This is used for VBUS pulsing during SRP.	R/W	0

Table 127. OTG Status and Control register (OTGSC - address 0x1900 01A4) bit description ...continued

Bit	Symbol	Value	Description	Access	Reset value
2	HAAR		Hardware assist auto_reset	R/W	0
		1	Enable automatic reset after connect on host port.		
		0	Disabled		
3	OT		OTG termination This bit must be set to 1 when the OTG controller is in device mode. This controls the pull-down on USB_DM.	R/W	0
4	DP		Data pulsing Setting this bit to 1 causes the pull-up on USB_DP to be asserted for data pulsing during SRP.	R/W	0
5	IDPU		ID pull-up. This bit provides control over the pull-up resistor.	R/W	1
		1	Pull-up on.		
		0	Pull-up off. The ID bit will not be sampled.		
6	HADP		Hardware assist data pulse Write a 1 to start data pulse sequence.	R/W	0
7	HABA		Hardware assist B-disconnect to A-connect	R/W	0
		1	Enable automatic B-disconnect to A-connect sequence.		
		0	Disabled.		
<b>OTG status inputs</b>					
8	ID		USB ID	RO	0
		1	B-device		
		0	A-device		
9	AVV		A-VBUS valid Reading 1 indicates that VBUS is above the A-VBUS valid threshold.	RO	0
10	ASV		A-session valid Reading 1 indicates that VBUS is above the A-session valid threshold.	RO	0
11	BSV		B-session valid Reading 1 indicates that VBUS is above the B-session valid threshold.	RO	0
12	BSE		B-session end Reading 1 indicates that VBUS is below the B-session end threshold.	RO	0
13	1mST		1 millisecond timer toggle This bit toggles once per millisecond.	RO	0
14	DPS		Data bus pulsing status Reading a 1 indicates that data bus pulsing is detected on the port.	RO	0
15	-	-	reserved		0
<b>OTG interrupt status</b>					
16	IDIS		USB ID interrupt status This bit is set when a change on the ID input has been detected. Software must write a 1 to this bit to clear it.	R/WC	0

Table 127. OTG Status and Control register (OTGSC - address 0x1900 01A4) bit description ...continued

Bit	Symbol	Value	Description	Access	Reset value
17	AVVIS		A-VBUS valid interrupt status This bit is set then VBUS has either risen above or fallen below the A-VBUS valid threshold (4.4 V on an A-device). Software must write a 1 to this bit to clear it.	R/WC	0
18	ASVIS		A-Session valid interrupt status This bit is set then VBUS has either risen above or fallen below the A-session valid threshold (0.8 V). Software must write a 1 to this bit to clear it.	R/WC	0
19	BSVIS		B-Session valid interrupt status This bit is set then VBUS has either risen above or fallen below the B-session valid threshold (0.8 V). Software must write a 1 to this bit to clear it.	R/WC	0
20	BSEIS		B-Session end interrupt status This bit is set then VBUS has fallen below the B-session end threshold. Software must write a 1 to this bit to clear it.	R/WC	0
21	1msS		1 millisecond timer interrupt status This bit is set once every millisecond. Software must write a 1 to this bit to clear it.	R/WC	0
22	DPIS		Data pulse interrupt status This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when the CM bit in USBMODE = Host (11) and the PortPower bit in PORTSC = Off (0). Software must write a 1 to this bit to clear it.	R/WC	0
23	-	-	reserved		0
<b>OTG interrupt enable</b>					
24	IDIE		USB ID interrupt enable Setting this bit enables the interrupt. Writing a 0 disables the interrupt.	R/W	0
25	AVVIE		A-VBUS valid interrupt enable Setting this bit enables the A-VBUS valid interrupt. Writing a 0 disables the interrupt.	R/W	0
26	ASVIE		A-session valid interrupt enable Setting this bit enables the A-session valid interrupt. Writing a 0 disables the interrupt	R/W	0
27	BSVIE		B-session valid interrupt enable Setting this bit enables the B-session valid interrupt. Writing a 0 disables the interrupt.	R/W	0
28	BSEIE		B-session end interrupt enable Setting this bit enables the B-session end interrupt. Writing a 0 disables the interrupt.	R/W	0

31	-	-	Reserved	-	0

#### 4.2.16 USB Mode register (USBMODE)

The USBMODE register sets the USB mode for the OTG controller. The possible modes are Device, Host, and Idle mode for OTG operations.

##### 4.2.16.1 Device mode

Table 128. USB Mode register (USBMODE - address 0x1900 01A8) bit description - device mode

Bit	Symbol	Value	Description	Access	Reset value
1:0	CM[1:0]		Controller mode The controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register.	R/ WO	00
		00	Idle		
		01	Reserved		
		10	Device controller		
		11	Host controller		
2	ES		Endian select This bit can change the byte ordering of the transfer buffers to match the host microprocessor bus architecture. The bit fields in the microprocessor interface and the DMA data structures (including the setup buffer within the device QH) are unaffected by the value of this bit, because they are based upon 32-bit words.	R/W	0
		1	Big endian: first byte referenced in most significant byte of 32-bit word.		
		0	Little endian: first byte referenced in least significant byte of 32-bit word.		
3	SLOM		Setup Lockout mode In device mode, this bit controls behavior of the setup lock mechanism. See <a href="#">Section 8-8.8</a> .	R/W	0
		1	Setup Lockouts Off (DCD requires the use of Setup Buffer Tripwire in USBCMD)		
		0	Setup Lockouts on		

Table 128. USB Mode register (USBMODE - address 0x1900 01A8) bit description - device mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
4	SDIS		Stream disable mode	R/W	0
		1	Disabled. Setting this bit to one disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received will be responded to with a NYET handshake when stream disable is active.		
		0	Not disabled		
5	VBPS		Not used in device mode.	-	0
31:6	-	-	reserved		

#### 4.2.16.2 Host mode

Table 129. USB Mode register (USBMODE - address 0x1900 01A8) bit description - host mode

Bit	Symbol	Value	Description	Access	Reset value
1:0	CM[1:0]		Controller mode	R/ WO	00
		00	Idle		
		01	Reserved		
		10	Device controller		
		11	Host controller		
2	ES		Endian select	R/W	0
		1	Big endian: first byte referenced in most significant byte of 32-bit word.		
		0	Little endian: first byte referenced in least significant byte of 32-bit word.		
3	SLOM		Not used in host mode	-	0

Table 129. USB Mode register (USBMODE - address 0x1900 01A8) bit description - host mode ...continued

Bit	Symbol	Value	Description	Access	Reset value
4	SDIS		Stream disable mode	R/W	0
		1	<p>Disabled.</p> <p>Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the the TX latency is filled to capacity before the packet is launched onto the USB.</p> <p>Note: Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING to characterize the adjustments needed for the scheduler when using this feature.</p>		
		0	Not disabled		
5	VBPS		VBUS power select	R/WO	0
		0	vbus_pwr_select is set LOW.		
		1	vbus_pwr_select is set HIGH		
31:6	-	-	reserved		

### 4.3 Device endpoint registers

#### 4.3.1 USB Endpoint Setup Status register (ENDPSETUPSTAT)

Table 130. USB Endpoint Setup Status register (ENDPTSETUPSTAT - address 0x1900 01AC) bit description

Bit	Symbol	Description	Access	Reset value
3:0	ENDPT SETUP STAT[3:0]	<p>Setup endpoint status for logical endpoints 0 to 3.</p> <p>For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lockout mechanism is engaged.</p>	R/WC	0
31:3	-	reserved		

#### 4.3.2 USB Endpoint Prime register (ENDPTPRIME)

For each endpoint, software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed.

**Remark:** These bits will be momentarily set by hardware during hardware endpoint re-priming operations when a dTD is retired and the dQH is updated.

Table 131. USB Endpoint Prime register (ENDPTPRIME - address 0x1900 01B0) bit description

Bit	Symbol	Description	Access	Reset value
3:0	PERB[3:0]	Prime endpoint receive buffer for physical OUT endpoints 3 to 0. For each OUT endpoint, a corresponding bit is set to 1 by software to request a buffer be prepared for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. PERB0 = endpoint 0 ... PERB3 = endpoint 3	R/WS	0
15:4	-	reserved		
19:16	PETB[3:0]	Prime endpoint transmit buffer for physical IN endpoints 3 to 0. For each IN endpoint a corresponding bit is set to one by software to request a buffer be prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. PETB0 = endpoint 0 ... PETB3 = endpoint 3	R/WS	0
31:20	-	reserved		

### 4.3.3 USB Endpoint Flush register (ENDPTFLUSH)

Writing a one to a bit(s) in this register will cause the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer will continue until completion. Hardware will clear this register after the endpoint flush operation is successful.

Table 132. USB Endpoint Flush register (address 0x1900 01B4) bit description

Bit	Symbol	Description	Access	Reset value
3:0	FERB[3:0]	Flush endpoint receive buffer for physical OUT endpoints 3 to 0. Writing a one to a bit(s) will clear any primed buffers. FERB0 = endpoint 0 ... FERB3 = endpoint 3	R/WS	0

Table 132. USB Endpoint Flush register (address 0x1900 01B4) bit description

Bit	Symbol	Description	Access	Reset value
15:4	-	reserved		
19:16	FETB[3:0]	Flush endpoint transmit buffer for physical IN endpoints 3 to 0. Writing a one to a bit(s) will clear any primed buffers.  FETB0 = endpoint 0 ... FETB3 = endpoint 3	R/WS	0
31:20	-	reserved		

#### 4.3.4 USB Endpoint Status register (ENDPSTAT)

One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set by hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register.

**Remark:** These bits will be momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired and the dQH is updated.

Table 133. USB Endpoint Status register (address 0x1900 01B8) bit description

Bit	Symbol	Description	Access	Reset value
3:0	ERBR[3:0]	Endpoint receive buffer ready for physical OUT endpoints 3 to 0. This bit is set to 1 by hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. ERBR0 = endpoint 0 ... ERBR3 = endpoint 3	RO	0
15:4	-	reserved		
19:16	ETBR[3:0]	Endpoint transmit buffer ready for physical IN endpoints 3 to 0. This bit is set to 1 by hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. ETBR0 = endpoint 0 ... ETBR3 = endpoint 3	RO	0
31:20	-	reserved		

#### 4.3.5 USB Endpoint Complete register (ENDPTCOMPLETE)

Each bit in this register indicates that a received/transmit event occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT.

Writing a one will clear the corresponding bit in this register.

Table 134. USB Endpoint Complete register (address 0x1900 01BC) bit description

Bit	Symbol	Description	Access	Reset value
3:0	ERCE[3:0]	Endpoint receive complete event for physical OUT endpoints 3 to 0. This bit is set to 1 by hardware when receive event (OUT/SETUP) occurred. ERCE0 = endpoint 0 ... ERCE3 = endpoint 3	R/WC	0
15:4	-	reserved		
19:16	ETCE[3:0]	Endpoint transmit complete event for physical IN endpoints 3 to 0. This bit is set to 1 by hardware when a transmit event (IN/INTERRUPT) occurred. ETCE0 = endpoint 0 ... ETCE3 = endpoint 3	R/WC	0
31:20	-	reserved		

#### 4.3.6 USB Endpoint 0 Control register (ENDPTCTRL0)

This register initializes endpoint 0 for control transfer. Endpoint 0 is always a control endpoint.

Table 135. USB Endpoint 0 Control register (ENDPTCTRL0 - address 0x1900 01C0) bit description

Bit	Symbol	Value	Description	Access	Reset value
0	RXS	1	Rx endpoint stall Endpoint stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software, or it will automatically be cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDSETUPSTAT bit is cleared. <a href="#">[1]</a>	R/W	0
		0	Endpoint ok.		
1	-	-	reserved		
3:2	RXT[1:0]	00	Endpoint type Endpoint 0 is always a control endpoint.	R/W	00
6:4	-	-	reserved		
7	RXE	1	Rx endpoint enable Endpoint enabled. Control endpoint 0 is always enabled. This bit is always 1.	RO	1
15:8	-	-	reserved		

**Table 135. USB Endpoint 0 Control register (ENDPTCTRL0 - address 0x1900 01C0) bit description ...continued**

Bit	Symbol	Value	Description	Access	Reset value
16	TXS		Tx endpoint stall	R/W	
		1	Endpoint stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software, or it will automatically be cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDSETUPSTAT bit is cleared. <a href="#">[1]</a>		
		0	Endpoint ok.		
17	-	-	reserved		
19:18	TXT[1:0]	00	Endpoint type Endpoint 0 is always a control endpoint.	RO	00
22:20	-	-	reserved		
23	TXE	1	Tx endpoint enable Endpoint enabled. Control endpoint 0 is always enabled. This bit is always 1.	RO	1
31:24	-	-	reserved		

- [1] There is a slight delay (50 clocks max) between the ENPTSETUPSTAT being cleared and hardware continuing to clear this bit. In most systems it is unlikely that the DCD software will observe this delay. However, should the DCD notice that the stall bit is not set after writing a one to it, software should continually write this stall bit until it is set or until a new setup has been received by checking the associated ENDPTSETUPSTAT bit.

### 4.3.7 Endpoint 1 to 3 control registers (ENDPTCTRL1 to ENDPTCTRL3)

Each endpoint that is not a control endpoint has its own register to set the endpoint type and enable or disable the endpoint.

**Remark:** The reset value for all endpoint types is the control endpoint. If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled, then the endpoint type of the unused direction must be changed from the control type to any other type (e.g. bulk). Leaving an unconfigured endpoint control will cause undefined behavior for the data PID tracking on the active endpoint.

**Table 136. USB Endpoint 1 to 3 control registers (ENDPTCTRL1 to ENDPTCTRL3 - address 0x1900 01C4 to 0x1900 01CC) bit description**

Bit	Symbol	Value	Description	Access	Reset value
0	RXS		Rx endpoint stall	R/W	0
		1	Endpoint stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software, or it will automatically be cleared upon receipt of a new SETUP request. <a href="#">[1]</a>		
		0	Endpoint ok. This bit will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.		

**Table 136. USB Endpoint 1 to 3 control registers (ENDPTCTRL1 to ENDPTCTRL3 - address 0x1900 01C4 to 0x1900 01CC) bit description ...continued**

		1	Disabled		
		0	Enabled		
22	TXR		Tx data toggle reset	WS	1
			Write 1 to reset the PID sequence. Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.		
23	TXE		Tx endpoint enable	R/W	0
			<b>Remark:</b> An endpoint should be enabled only after it has been configured		
		1	Endpoint enabled.		
		0	Endpoint disabled.		
31:24	-	-	reserved		0

[1] For control endpoints only: There is a slight delay (50 clocks max) between the ENPTSETUPSTAT being cleared and hardware continuing to clear this bit. In most systems it is unlikely that the DCD software will observe this delay. However, should the DCD notice that the stall bit is not set after writing a one to it, software should continually write this stall bit until it is set or until a new setup has been received by checking the associated ENDPTSETUPSTAT bit.

## 5. Functional description

### 5.1 OTG core

The OTG core forms the main digital part of the USB-OTG. See the *USB EHCI specification* for details about this core.

### 5.2 Host data structures

See *Chapter 4 of Enhanced Host Controller Interface Specification for Universal Serial Bus 1.0*.

### 5.3 Host operational model

See *Chapter 3 of Enhanced Host Controller Interface Specification for Universal Serial Bus 1.0*.

### 5.4 ATX\_RGEN module

There are a number of requirements for the reset signal towards the ATX transceiver, these are as follows:

- it requires the clocks to be running for a reset to occur correctly.

- it must see a rising edge of reset to correctly reset the clock generation module.
- the reset must be a minimum of 133 ns ( $4 \times 30$  MHz clock cycles) in duration to reset all logic correctly.

The ATX\_RGEN module generates a reset signal towards the ATX fulfilling above 3 requirements, no matter how the AHB reset looks like.

## 5.5 ATX transceiver

The USB-OTG has a USB transceiver with UTMI+ interface. It contains the required transceiver OTG functionality; this includes:

- VBUS sensing for producing the session-valid and VBUS-valid signals.
- sampling of the USB\_ID input for detection of A-device or B-device connection.
- charging and discharging of VBUS for starting and ending a session as B-device.

## 5.6 Modes of operation

In general, the USB-OTG can be operating either in host mode or in device mode. Software must put the core in the appropriate mode by setting the USBMODE.CM field ('11' for host mode, '10' for device mode).

The USBMODE.CM field can also be equal to '00', which means that the core is in idle mode (neither host nor device mode). This will happen after the following:

- a hardware reset.
- a software reset via the USBCMD.RST bit; e.g. when switching from host mode to device mode as part of the HNP protocol (or vice versa), software must issue a software reset by which the core will be to the idle state; this will happen in a time frame dependent on the software.

## 5.7 SOF/VF indicator

The USB-OTG generates a SOF/VF indicator signal, which can be used by user specific external logic.

In FS mode, the SOF/VF indicator signal has a frequency equal to the frame frequency, which is about 1 kHz. The signal is high for half of the frame period and low for the other half of the frame period. The positive edge is aligned with the start of a frame (= SOF).

In HS mode, the SOF/VF indicator signal has a frequency equal to the virtual frame frequency. The signal is high for half of the virtual frame period and low for the other half of the virtual frame period. The positive edge is aligned with the start of a virtual frame (= VF).

The length of the virtual frame is defined as:  $VF = \text{microframe} \times 2^{\text{bInterval}}$ ;

bInterval is specified in the 4-bit programmable BINTERVAL.BINT register field. The minimum value of bInterval is 0, the maximum value is 15.

In suspend mode the SOF/VF indicator signal is turned off (= remains low).

## 5.8 Hardware assist

The hardware assist provides automated response and sequencing that may not be possible in software if there are significant interrupt latency response times. The use of this additional circuitry is optional and can be used to assist the following three state transitions by setting the appropriate bits in the OTGSC register:

- Auto reset (set bit HAAR).
- Data pulse (set bit HADP).
- B-disconnect to A-connect (set bit HABA).

### 5.8.1 Auto reset

When the HAAR in the OTGSC register is set to one, the host will automatically start a reset after a connect event. This shortcuts the normal process where software is notified of the connect event and starts the reset. Software will still receive notification of the connect event (CCS bit in the PORTSC register) but should not write the reset bit in the USBCMD register when the HAAR is set. Software will be notified again after the reset is complete via the enable change bit in the PORTSC register which causes a port change interrupt.

This assist will ensure the OTG parameter `TB_ACON_BSE0_MAX = 1 ms` is met (see *OTG specification* for an explanation of the OTG timing requirements).

### 5.8.2 Data pulse

Writing a one to HADP in the OTGSC register will start a data pulse of approximately 7 ms in duration and then automatically cease the data pulsing. During the data pulse, the DP bit will be set and then cleared. This automation relieves software from accurately controlling the data-pulse duration. During the data pulse, the HCD can poll to see that the HADP and DP bit have returned low to recognize the completion, or the HCD can simply launch the data pulse and wait to see if a VBUS Valid interrupt occurs when the A-side supplies bus power.

This assist will ensure data pulsing meets the OTG requirement of  $> 5$  ms and  $< 10$  ms.

### 5.8.3 B-disconnect to A-connect (Transition to the A-peripheral state)

During HNP, the B-disconnect occurs from the OTG A\_suspend state, and within 3 ms, the A-device must enable the pullup on the DP leg in the A-peripheral state. For the hardware assist to begin the following conditions must be met:

- HABA is set.
- Host controller is in suspend mode.
- Device is disconnecting.

The hardware assist consists of the following steps:

1. Hardware resets the OTG controller (writes 1 to the RST bit in USBCMD).
2. Hardware selects the device mode (writes 10 to bits CM[1:0] in USBMODE).
3. Hardware sets the RS bit in USBCMD and enables the necessary interrupts:
  - USB reset enable (URE) - enables interrupt on USB bus reset to device.
  - Sleep enable (SLE) - enables interrupt on device suspend.

- Port change detect enable (PCE) - enables interrupt on device connect.

When software has enabled this hardware assist, it must not interfere during the transition and should not write any register in the OTG core until it gets an interrupt from the device controller signifying that a reset interrupt has occurred or until it has verified that the core has entered device mode. HCD/DCD must not activate the core soft reset at any time since this action is performed by hardware. During the transition, the software may see an interrupt from the disconnect and/or other spurious interrupts (i.e. SOF/etc.) that may or may not cascade and may be cleared by the soft reset depending on the software response time.

After the core has entered device mode with help of the hardware assist, the DCD must ensure that the ENDPTLISTADDR is programmed properly before the host sends a setup packet. Since the end of the reset duration, which may be initiated quickly (a few microseconds) after connect, will require at a minimum 50 ms, this is the time for which the DCD must be ready to accept setup packets after having received notification that the reset has been detected or simply that the OTG is in device mode whichever occurs first.

If the A-peripheral fails to see a reset after the controller enters device mode and engages the D+-pullup, the device controller interrupts the DCD signifying that a suspend has occurred. This assist will ensure the parameter TA\_BDIS\_ACON\_MAX = 3ms is met.

## 6. Deviations from EHCI standard

For the purposes of a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Device operation and On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is specific to the LPC315x. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator – Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- On-The-Go Operation - This design includes an On-The-Go controller.

### 6.1 Embedded Transaction Translator function

The USB-HS OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

### 6.1.1 Capability registers

The following items have been added to the capability registers to support the embedded Transaction Translator Function:

- N\_TT bits added to HCSPARAMS – Host Control Structural Parameters (see [Table 8–99](#)).
- N\_PTT added to HCSPARAMS – Host Control Structural Parameters (see [Table 8–99](#)).

### 6.1.2 Operational registers

The following items have been added to the operational registers to support the embedded TT:

- New register TTCTRL (see [Section 8–4.2.7](#)).
- Two-bit Port Speed (PSPD) bits added to the PORTSC1 register (see [Section 8–4.2.14](#)).

### 6.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (i.e. Chirp completes successfully). Since this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in PORTSC1 (see [Section 8–4.2.14](#)).

**Table 137. Handling of directly connected full-speed and low-speed devices**

Standard EHCI model	EHCI with embedded Transaction Translator
After the port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After the port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSC1.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSC1.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X, where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (i.e. Split target hub).	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached, where HubAddr = TTHA (TTHA is programmable and defaults to 0) and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (i.e. Split target hub is the root hub).

### 6.1.4 Data structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator. Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) – Async. (Bulk/Control Endpoints) Periodic (Interrupt)
  - Hub Address = TTHA (default TTHA = 0)
  - Transactions to direct attached device/hub: QH.EPS = Port Speed
  - Transactions to a device downstream from direct attached FS hub: QH.EPS = Downstream Device Speed

**Remark:** When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behavior may result.

2. siTD (for direct attach FS) – Periodic (ISO Endpoint)

all FS ISO transactions:

Hub Address = (default TTHA = 0)

siTD.EPS = 00 (full speed)

Maximum Packet Size must less than or equal to 1023 or undefined behavior may result.

### 6.1.5 Operational model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification) and for the EHCI controller moving packets between system memory and a USB-HS hub. Since the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

#### 6.1.5.1 Micro-frame pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators. Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

### 6.1.6 Split state machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

**Table 138. Split state machine properties**

	Condition	Emulate TT response
Start-split	All asynchronous buffers full.	NAK
	All periodic buffers full.	ERR
	Success for start of Async. Transaction.	ACK
	Start Periodic Transaction.	No Handshake (Ok)
Complete-split	Failed to find transaction in queue.	Bus Time Out
	Transaction in Queue is Busy.	NYET
	Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

### 6.1.7 Asynchronous Transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

1. *USB 2.0 specification, section 11.17.3*: Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
2. *USB 2.0 specification, section 11.17.4*: Transaction tracking for 2 data pipes.
3. *USB 2.0 specification, section 11.17.5*: Clear\_TT\_Buffer capability provided though the use of the TTCTRL register.

### 6.1.8 Periodic Transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

1. *USB 2.0 specs, section 11.18.6.[1-2]*:
  - Abort of pending start-splits:
    - EOF (and not started in micro-frames 6)
    - Idle for more than 4 micro-frames
  - Abort of pending complete-splits:
    - EOF
    - Idle for more than 4 micro-frames
2. *USB 2.0 specs, section 11.18.6.[7-8]*:
  - Transaction tracking for up to 16 data pipes:

Some applications may not require transaction tracking up to a maximum of 16 periodic data pipes. The option to limit the tracking to only 4 periodic data pipes exists in the by changing the configuration constant `VUSB_HS_TT_PERIODIC_CONTEXTS` to 4. The result is a significant gate count savings to the core given the limitations implied.

**Remark:** Limiting the number of tracking pipes in the EMbedded TT to four (4) will impose the restriction that no more than 4 periodic transactions (INTERRUPT/ISOCRONOUS) can be scheduled through the embedded TT per frame. The number 16 was chosen in the USB specification because it is sufficient to ensure that the high-speed to full-speed periodic pipeline can remain full. Keeping the pipeline full puts no constraint on the number of periodic transactions that can be scheduled in a frame and the only limit becomes the flight time of the packets on the bus.

- Complete-split transaction searching:

There is no data schedule mechanism for these transactions other than micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

### 6.1.9 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the `N_TT` field in the `HCSPARAMS` – Host Control Structural Parameters register.

## 6.2 Device operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

### 6.2.1 USBMODE register

Given that the dual-role controller is initialized in neither host nor device mode, the `USBMODE` register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

### 6.2.2 Non-Zero Fields the register file

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode.

### 6.2.3 SOF interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode. EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USBSTS ([Section 8–4.2.2](#)) and USBINTR ([Section 8–4.2.3](#)) registers.

## 6.3 Miscellaneous variations from EHCI

### 6.3.1 Discovery

#### 6.3.1.1 Port reset

The port connect methods specified by EHCI require setting the port reset bit in the PORTSCx register for a duration of 10 ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the device.
- Software shall write a '0' to the reset the device after 10 ms.

This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.

- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

#### 6.3.1.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed – This information is redundant with the 2-bit Port Speed indicator above.

## 7. Device data structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space.

**Remark:** The Software must ensure that no interface data structure reachable by the Device controller crosses a 4k-page boundary

The data structures defined in the chapter are (from the device controller’s perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

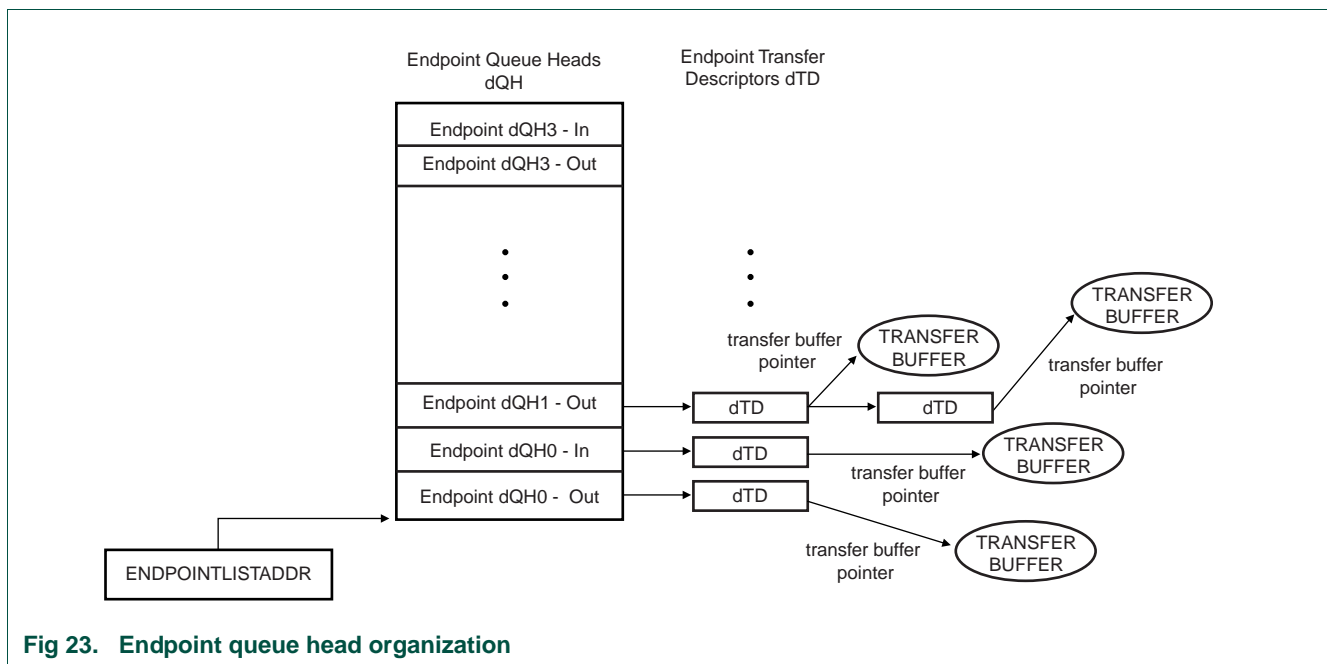

Fig 23. Endpoint queue head organization

Device queue heads are arranged in an array in a continuous area of memory pointed to by the ENDPOINTLISTADDR pointer. The even –numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

**Remark:** The Endpoint Queue Head List must be aligned to a 2k boundary.

### 7.1 Endpoint queue head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the

dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

### 7.1.1 Endpoint capabilities and characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

**Table 139. Endpoint capabilities and characteristics**

Access	Bit	Name	Description
RO	31:30	MULT	<p>Number of packets executed per transaction descriptor</p> <p>00 - Execute N transactions as demonstrated by the USB variable length protocol where N is computed using Max_packet_length and the Total_bytes field in the dTD.</p> <p>01 - Execute one transaction</p> <p>10 - Execute two transactions</p> <p>11 - Execute three transactions</p> <p><b>Remark:</b> Non-isochronous endpoints must set MULT = 00.</p> <p><b>Remark:</b> Isochronous endpoints must set MULT = 01, 10, or 11 as needed.</p>
RO	29	ZLT	<p>Zero length termination select</p> <p>This bit is used for non-isochronous endpoints to indicate when a zero-length packet is received to terminate transfers in case the total transfer length is "multiple".</p> <p>0 - Enable zero-length packet to terminate transfers equal to a multiple of Max_packet_length (default).</p> <p>1 - Disable zero-length packet on transfers that are equal in length to a multiple Max_packet_length.</p>
RO	28:27	-	reserved
RO	26:16	Max_packet_length	Maximum packet size of the associated endpoint (< 1024)
RO	15	IOS	<p>Interrupt on setup</p> <p>This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.</p>
RO	14:0	-	reserved

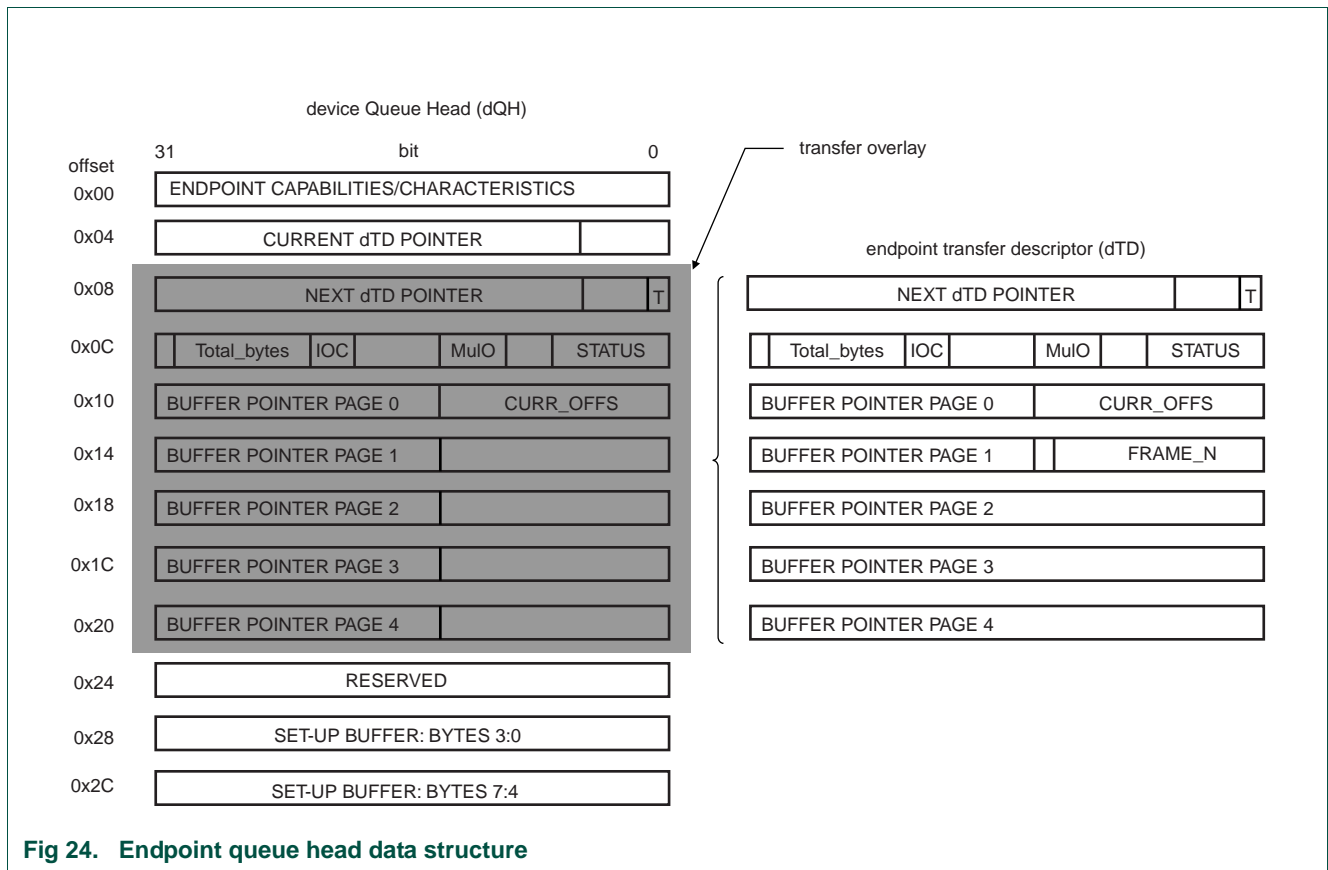

Fig 24. Endpoint queue head data structure

### 7.1.2 Transfer overlay

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue. See dTD for a description of the overlay fields.

### 7.1.3 Current dTD pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

**Table 140. Current dTD pointer**

Access	Bit	Name	Description
R/W (hardware only)	31:5	Current_TD_pointer	Current dTD pointer This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the device controller to the next dTD pointer during endpoint priming or queue advance.
-	4:0	-	reserved

### 7.1.4 Set-up buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

**Remark:** Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

**Table 141. Set-up buffer**

Dword	Access	Bit	Name	Description
1	R/W	31:0	BUF0	Setup buffer 0 This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	R/W	31:0	BUF1	Setup buffer 1 This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

## 7.2 Endpoint transfer descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Link Pointer, which should only be modified as described in [Section 8–8.11](#).

**Table 142. Next dTD pointer**

Access	Bit	Name	Description
RO	31:5	Next_link_pointer	Next link pointer This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
	4:1	-	reserved
	0	T	Terminate This bit indicates to the device controller when there are no more valid entries in the queue. 1 - pointer is invalid 0 - Pointer is valid, i.e. pointer points to a valid transfer element descriptor.

Table 143. dTD token

Access	Bit	Name	Description
-	31	-	reserved
R/W	30:16	Total_bytes	<p>Total bytes</p> <p>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and it is decremented only when the transaction has been completed successfully.</p> <p>The maximum value software can write into this field is 0x5000 (5 x 4 kB) for the maximum number of bytes five page pointers can access. Although it is possible to create a transfer up to 20 kB this assumes that the first offset into the first page is zero. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16 kB. Therefore, the maximum recommended Total-Bytes = 16 kB (0x4000).</p> <p>If Total_bytes = 0 when the host controller fetches this transfer descriptor and the active bit is set in the Status field of this dTD, the device controller executes a zero-length transaction and retires the dTD.</p> <p><b>Remark:</b> For IN transfers, it is not a requirement that Total_bytes is an even multiple of Max_packet_length. If software builds such a dTD, the last transaction will always be less than Max_packet_length.</p>
RO	15	IOC	<p>Interrupt on complete</p> <p>This bit is used to indicate if USBINT will be set when the device controller is finished with this dTD.</p> <p>1 - USBINT set.</p> <p>0 - USBINT not set.</p>
-	14:12	-	reserved

Table 143. dTD token ...continued

Access	Bit	Name	Description
RO	11:10	MultO	Multiplier Override (see <a href="#">Section 8–7.2.1</a> for an example) This field can be used for transmit ISOs to override the MULT field in the dQH. This field must be zero for all packet types that are not transmit-ISO. 00 - Execute N transactions as demonstrated by the USB variable length protocol where N is computed using Max_packet_length and the Total_bytes field in the dTD. 01 - Execute one transaction 10 - Execute two transactions 11 - Execute three transactions <b>Remark:</b> Non-ISO and Non-TX endpoints must set MultO="00".
	9:8	-	reserved
R/W	7:0	Status	Status This field is used by the device controller to communicate individual execution states back to the software. This field contains the status of the last transaction performed on this dTD. Bit 7 = 1 - status: Active Bit 6 = 1 - status: Halted Bit 5 = 1 - status: Buffer Error Bit 4 - reserved Bit 3 = 1 - status: Transaction Error Bit 2 - reserved Bit 1 - reserved Bit 0 - reserved

Table 144. dTD buffer page pointer list

Access	Bit	Name	Description
RO	31:12	BUFF_P	Selects the page offset in memory for the packet buffer. Non-virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
	page 0: 11:0	CURR_OFFS	Offset into the 4 kB buffer where the packet is to begin.
	page 1: 10:0	FRAME_N	Written by the device controller to indicate the frame number in which a packet finishes. This is typically used to correlate relative completion times of packets on an isochronous endpoint.

### 7.2.1 Determining the number of packets for Isochronous IN endpoints

The following examples show how the MULT field in the dQH and the MultO in the dTD are used to control the number of packets sent in an In-transaction for an isochronous endpoint:

#### Example 1

MULT = 3; Max\_packet\_size = 8; Total\_bytes = 15; MultO = 0 (default)

In this case three packets are sent: Data2 (8 bytes), Data1 (7 bytes), Data0 (0 bytes).

### Example 2

MULT = 3; Max\_packet\_size = 8; Total\_bytes = 15; MultO = 2

In this case two packets are sent: Data1 (8 bytes), Data0 (7 bytes).

To optimize efficiency for IN transfers, software should compute MultO = greatest integer of (Total\_bytes/Max\_packet\_size). If Total\_bytes = 0, then MultO should be 1.

## 8. Device operational model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

### 8.1 Device controller initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB\_DM is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USBMODE register to device mode.

**Remark:** Transitioning from host mode to device mode requires a device controller reset before modifying USBMODE.

2. Allocate and Initialize device queue heads in system memory (see [Section 8-7](#)).

Minimum: Initialize device queue heads 0 Tx & 0 Rx.

**Remark:** All device queue heads associated with control endpoints must be initialized before the control endpoint is enabled. Non-Control device queue heads must be initialized before the endpoint is used and not necessarily before the endpoint is enabled.

3. Configure ENDPOINTLISTADDR Pointer (see [Section 8-4.2.6](#)).

4. Enable the microprocessor interrupt associated with the USB-HS core.

Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend (see [Table 8-108](#)).

5. Set Run/Stop bit to Run Mode.

After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

**Remark:** Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework command set (see *USB Specification Rev. 2.0, chapter 9*).

## 8.2 Port state and control

From a chip or system reset, the device controller enters the powered state. A transition from the powered state to the attach state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port will enter the defaultFS or defaultHS state in accordance with the reset protocol described in *Appendix C.2 of the USB Specification Rev. 2.0*. The following state diagram depicts the state of a USB 2.0 device.

Fig 25. Device state diagram

The states powered, attach, default FS/HS, suspend FS/HS are implemented in the device controller and are communicated to the DCD using the following status bits:

- DCSuspend - see [Table 8-106](#).
- USB reset received - see [Table 8-106](#).
- Port change detect - see [Table 8-106](#).
- High-speed port - see [Table 8-124](#).

It is the responsibility of the DCD to maintain a state variable to differentiate between the DefaultFS/HS state and the Address/Configured states. Change of state from Default to Address and the configured states is part of the enumeration process described in the *device framework section of the USB 2.0 Specification*.

As a result of entering the Address state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the Configured indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

### 8.3 Bus reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

- Clear all setup token semaphores by reading the ENDPTSETUPSTAT register and writing the same value back to the ENDPTSETUPSTAT register.
- Clear all the endpoint complete status bits by reading the ENDPTCOMPLETE register and writing the same value back to the ENDPTCOMPLETE register.
- Cancel all primed status by waiting until all bits in the ENDPTPRIME are 0 and then writing 0xFFFFFFFF to ENDPTFLUSH.
- Read the reset bit in the PORTSCx register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare).

**Remark:** A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

- Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated. At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.
- After a Port Change Detect, the device has reached the default state and the DCD can read the PORTSCx to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the *USB2.0 specification Chapter 9 - Device Framework*.

**Remark:** The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.

## 8.4 Suspend/resume

### 8.4.1 Suspend

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

#### 8.4.1.1 Operational model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming DC Suspend Interrupt is enabled). When the DCSuspend bit in the PORTSCx is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation. Information on the bus power limits in suspend state can be found in *USB 2.0 specification*.

### 8.4.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the PORTSCx while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

**Remark:** Before resume signaling can be used, the host must enable it by using the Set Feature command defined in *device framework (chapter 9) of the USB 2.0 Specification*.

## 8.5 Managing endpoints

The *USB 2.0 specification* defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints support by USB include bulk, interrupt, and isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the *USB 2.0 specification*.

The LPC315x supports up to four endpoints.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a queue head allocated in memory. If the maximum of 4 endpoint numbers, one for each endpoint direction are being used by the device controller, then 8 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

### 8.5.1 Endpoint initialization

After hardware reset, all endpoints except endpoint zero are un-initialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRLx register (see [Table 8-136](#)). Each 32-bit ENDPTCTRLx is split into an upper and lower half. The lower half of ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization.

**Table 145. Device controller endpoint initialization**

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 - control
	01 - isochronous
	10 - bulk
	11 - interrupt
Endpoint Stall	0

## 8.5.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL:

1. The first occasion is the **functional stall**, which is a condition set by the DCD as described in the *USB 2.0 device framework (chapter 9)*. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.
2. A **protocol stall**, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

**Remark:** Any write to the ENDPTCTRLx register during operational mode must preserve the endpoint type field (i.e. perform a read-modify-write).

**Table 146. Device controller stall response matrix**

USB packet	Endpoint STALL bit	Effect on STALL bit	USB response
SETUP packet received by a non-control endpoint.	N/A	None	STALL
IN/OUT/PING packet received by a non-control endpoint.	1	None	STALL
IN/OUT/PING packet received by a non-control endpoint.	0	None	ACK/NAK/NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint.	1	None	STALL
IN/OUT/PING packet received by a control endpoint.	0	None	ACK/NAK/NYET

## 8.5.3 Data toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, refer to *the USB 2.0 specification*.

### 8.5.3.1 Data toggle reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the ENDPTCTRLx register. This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

### 8.5.3.2 Data toggle inhibit

**Remark:** This feature is for test purposes only and should never be used during normal device controller operation.

Setting the data toggle Inhibit bit active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state. In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

## 8.6 Operational model for packet transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were designed so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is designed in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be designed properly to use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

### 8.6.1 Priming transmit endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received. After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to four endpoints.

After a priming request is complete, an endpoint state of primed is indicated in the ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB. Since only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the

transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. On the LPC315x, 128 x 36 bit dual port memory FIFOs are used for each IN endpoint.

**8.6.2 Priming receive endpoints**

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host. Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

**8.7 Interrupt/bulk endpoint operational model**

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$$

With Zero Length Termination (ZLT) = 1

$$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$$

**Table 147. Variable length transfer protocol example (ZLT = 0)**

Bytes (dTD)	Max Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	3	256	256	0
512	512	2	512	0	-

**Table 148. Variable length transfer protocol example (ZLT = 1)**

Bytes (dTD)	Max Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	2	256	256	-
512	512	1	512	-	-

**Remark:** The MULT field in the dQH must be set to “00” for bulk, interrupt, and control endpoints.

TX-dTD is complete when all packets described dTD were successfully transmitted. Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction. On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

**Remark:** All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

### 8.7.1 Interrupt/bulk endpoint bus response matrix

**Table 149. Interrupt/bulk endpoint bus response matrix**

Token type	STALL	Not primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	n/a	n/a
In	STALL	NAK	Transmit	BS error	n/a
Out	STALL	NAK	Receive and NYET/ACK	n/a	NAK
Ping	STALL	NAK	ACK	n/a	n/a
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

[1] BS error = Force Bit Stuff Error

[2] NYET/ACK – NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

[3] SYSERR – System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

## 8.8 Control endpoint operational model

### 8.8.1 Setup phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

### 8.8.1.1 Setup Packet Handling using setup lockout mechanism

After receiving an interrupt and inspecting USBMODE to determine that a setup packet was received on a particular pipe:

1. Duplicate contents of dQH.SsetupBuffer into local software byte array.
2. Write '1' to clear corresponding ENDPTSETUPSTAT bit and thereby disabling Setup Lockout (i.e. the Setup Lockout activates as soon as a setup arrives. By writing to the ENDPTSETUPSTAT, the device controller will accept new setup packets.).
3. Process setup packet using local software byte array copy and execute status/handshake phases.

**Remark:** After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

4. Before priming for status/handshake phases ensure that ENDPTSETUPSTAT is '0'. The time from writing a '1' to ENDPTSETUPSTAT and reading back a '0' may vary according to the type of traffic on the bus up to nearly a 1ms, however the it is absolutely necessary to ensure ENDPTSETUPSTAT has transitioned to '0' after step 1) and before priming for the status/handshake phases.

**Remark:** To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions

### 8.8.1.2 Setup Packet Handling using trip wire mechanism

- Disable Setup Lockout by writing '1' to Setup Lockout Mode (SLOM) in USBMODE. (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

**Remark:** Leaving the Setup Lockout Mode As '0' will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting ENDPTSETUPSTAT to determine that a setup packet was received on a particular pipe:
  - a. Write '1' to clear corresponding bit ENDPTSETUPSTAT.
  - b. Duplicate contents of dQH.SetupBuffer into local software byte array.
  - c. Write '1' to Setup Tripwire (SUTW) in USBCMD register.
  - d. Read Setup TripWire (SUTW) in USBCMD register. (if set - continue; if cleared - go to b).
  - e. Write '0' to clear Setup Tripwire (SUTW) in USBCMD register.

- f. Process setup packet using local software byte array copy and execute status/handshake phases.
  - g. Before priming for status/handshake phases ensure that ENDPTSETUPSTAT is '0'.
- A poll loop should be used to wait until ENDPTSETUPSTAT transitions to '0' after step a) above and before priming for the status/handshake phases.
  - The time from writing a '1' to ENDPTSETUPSTAT and reading back a '0' is very short (~1-2 us) so a poll loop in the DCD will not be harmful.

**Remark:** After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

### 8.8.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the ENDPTPRIME register is zero and the associated bit in the ENDPTSTATUS register is a one. If a prime fails, i.e. The ENDPTPRIME bit goes to zero and the ENDPTSTATUS bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (ENDPTSTATUS) to enforce data coherency with the setup packet.

**Remark:** The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

**Remark:** Error handling of data phase packets is the same as bulk packets described previously.

### 8.8.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the ENDPTSETUPSTAT as described above in the data phase.

**Remark:** The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

**Remark:** Error handling of data phase packets is the same as bulk packets described previously.

### 8.8.4 Control endpoint bus response matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

**Table 150. Control endpoint bus response matrix**

Token type	Endpoint state					Setup lockout
	STALL	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	n/a	SYSERR	-
In	STALL	NAK	Transmit	BS error	n/a	n/a
Out	STALL	NAK	Receive and NYET/ACK	n/a	NAK	n/a
Ping	STALL	NAK	ACK	n/a	n/a	n/a
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	ignore

[1] BS error = Force Bit Stuff Error

[2] NYET/ACK – NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

[3] SYSERR – System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

### 8.9 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data, and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller is accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro) frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro) frame. Once an ISO transaction is started in a (micro) frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds

a fulfillment condition. The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data. Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the Transaction Error bit and the data is stored as usual for the application software to sort out.

### TX packet retired

- MULT counter reaches zero.
- Fulfillment Error [Transaction Error bit is set].
- # Packets Occurred > 0 AND # Packets Occurred < MULT.

**Remark:** For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

### RX packet retired

- MULT counter reaches zero.
- Non-MDATA Data PID is received.

**Remark:** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.

- Overflow Error:
  - Packet received is > maximum packet length. [Buffer Error bit is set].
  - Packet received exceeds total bytes allocated in dTD. [Buffer Error bit is set].
- Fulfillment error [Transaction Error bit is set]:
  - # Packets Occurred > 0 AND # Packets Occurred < MULT.
- CRC Error [Transaction Error bit is set]

**Remark:** For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro) frame to (micro) frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro) frames.

## 8.9.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

**Remark:** Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

### 8.9.2 Isochronous endpoint bus response matrix

Table 151. Isochronous endpoint bus response matrix

Token type	STALL	Not primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	n/a	n/a
In	NULL packet	NULL packet	Transmit	BS error	n/a
Out	Ignore	Ignore	Receive	n/a	Drop packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

[1] BS error = Force Bit Stuff Error

[2] NULL packet = Zero length packet.

### 8.10 Managing queue heads

Fig 26. Endpoint queue head diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown [Figure 8–26](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list

from the queue head. Therefore, software is required to track all transfer descriptors since pointers will no longer exist within the queue head once the dTD is retired (see [Section 8–8.11.1](#)).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

### 8.10.1 Queue head initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the `wMaxPacketSize` field as required by the *USB Chapter 9* or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth and in conjunction with the *USB Chapter 9 protocol*. Note: In FS mode, the multiplier field can only be 1 for ISO endpoints.
- Write the next dTD Terminate bit field to “1”.
- Write the Active bit in the status field to “0”.
- Write the Halt bit in the status field to “0”.

**Remark:** The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

### 8.10.2 Operational model for setup transfers

As discussed in section Control Endpoint Operational Model ([Section 8–8.8](#)), setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a “1” to the corresponding bit in `ENDPTSETUPSTAT`.

**Remark:** The acknowledge must occur before continuing to process the setup packet.

**Remark:** After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH – RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.

**Remark:** It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

4. Decode setup packet and prepare data phase [optional] and status phase transfer as require by the *USB Chapter 9* or application specific protocol.

## 8.11 Managing transfers with transfer descriptors

### 8.11.1 Software link pointers

It is necessary for the DCD software to maintain head and tail pointers to the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list.

**Remark:** To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers but it still remains the responsibility of the DCD to maintain the pointers.

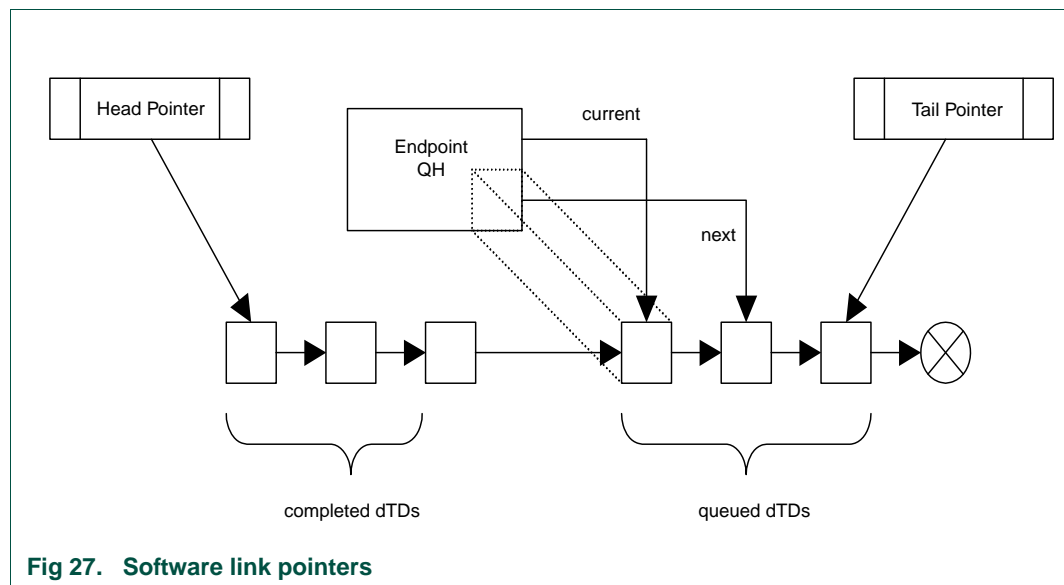

Fig 27. Software link pointers

### 8.11.2 Building a transfer descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs:

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000".

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to "1".
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to "1" and all remaining status bits set to "0".
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

### 8.11.3 Executing a transfer descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

#### Link list is empty

1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
2. Clear active and halt bits in dQH (in case set from a previous error).
3. Prime endpoint by writing '1' to correct bit position in ENDPTPRIME.

#### Link list is not empty

1. Add dTD to end of the linked list.
2. Read correct prime bit in ENDPTPRIME – if '1' DONE.
3. Set ATDTW bit in USBCMD register to '1'.
4. Read correct status bit in ENDPTSTAT. (Store in temp variable for later).
5. Read ATDTW bit in USBCMD register.
  - If '0' go to step 3.
  - If '1' continue to step 6.
6. Write ATDTW bit in USBCMD register to '0'.
7. If status bit read in step 4 (ENDPTSTAT reg) indicates endpoint priming is DONE (corresponding ERBRx or ETBRx is one): DONE.
8. If status bit read in step 4 is 0 then go to Linked list is empty: Step 1.

### 8.11.4 Transfer completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

**Remark:** Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

Active = 0  
Halted = 0  
Transaction Error = 0  
Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix (see [Table 8–152](#)).

In addition to checking the status bit, the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

### 8.11.5 Flushing/De-priming an endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.

**Remark:** Software note: This operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read ENDPTSTAT to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:

In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

### 8.11.6 Device error matrix

The [Table 8–152](#) summarizes packet errors that are not automatically handled by the Device Controller.

The following errors can occur:

**Overflow:** Number of bytes received exceeded max. packet size or total buffer length. This error will also set the Halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.

**ISO packet error:** CRC Error on received ISO packet. Contents not guaranteed to be correct.

**ISO fulfillment error:** Host failed to complete the number of packets defined in the dQH mult field within the given (micro) frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro) frame. During the "dead" (micro) frame, the Device Controller reports error on the pipe and primes for the following frame

Table 152. Device error matrix

Error	Direction	Packet type	Data buffer error bit	Transaction error bit
Overflow	Rx	Any	1	0
ISO packet error	Rx	ISO	0	1
ISO fulfillment error	Both	ISO	0	1

## 8.12 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

### 8.12.1 High-frequency interrupts

High frequency interrupts in particular should be handed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 153. High-frequency interrupt events

Execution order	Interrupt	Action
1a	USB interrupt: ENDPTSETUPSTATUS <a href="#">[1]</a>	Copy contents of setup buffer and acknowledge setup packet (as indicated in <a href="#">Section 8–8.10</a> ). Process setup packet according to <i>USB 2.0 Chapter 9</i> or application specific protocol.
1b	USB interrupt: ENDPTCOMPLETE <a href="#">[1]</a>	Handle completion of dTD as indicated in <a href="#">Section 8–8.10</a> .
2	SOF interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

[1] It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

### 8.12.2 Low-frequency interrupts

The low frequency events include the following interrupts. These interrupt can be handled in any order since they don't occur often in comparison to the high-frequency interrupts.

Table 154. Low-frequency interrupt events

Interrupt	Action
Port change	Change software state information.
Sleep enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

### 8.12.3 Error interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

Table 155. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ ENDPTCOMPLETE).
System error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

## 9. USB power optimization

The USB-HS core is a fully synchronous static design. The power used by the design is dependent on the implementation technology used to fabricate the design and on the application usage of the core. Applications that transfer more data or use a greater number of packets to be sent will consume a greater amount of power.

Because the design is synchronous and static, power may be conserved by reducing the transitions of the clock net. This may be done in several ways.

1. Reduce the clock frequency to the core. The clock frequency may not be reduced below the minimum recommended operating frequency of the core without first disabling the USB operation.
2. Reduce transition on the clock net through the use of clock gating methods. (The LPC315x is synthesized using this mechanism).
3. The clock may be shut off to the core entirely to conserve power. Again this may only be done after the USB operations on the bus have been disabled.

A device may suspend operations autonomously by disconnecting from the USB, or, in response to the suspend signaling, the USB has moved it into the suspend state. A host can suspend operation autonomously, or it can command portions or the entire USB to transition into the suspend state.

### 9.1 USB power states

The USB provides a mechanism to place segments of the USB or the entire USB into a low-power suspend state. USB bus powered devices are required to respond to a 3ms lack of activity on the USB bus by going into a suspend state. In the USB-HS core software is notified of the suspend condition via the transition in the PORTSC register. Optionally an interrupt can be generated which is controlled by the port change Detect Enable bit in the USBINTR control register. Software then has 7 ms to transition a bus powered device into the suspend state. In the suspend state, a USB device has a maximum USB bus power budget of 500 $\mu$ A. In general, to achieve that level of power conservation, most of the device circuits will need to be switched off, or clock at an extremely low frequency. This can be accomplished by suspending the clock.

The implementation of low power states in the USB-HS core is dependant on the use of the device role (host or peripheral), whether the device is bus powered, and the selected clock architecture of the core.

Bus powered peripheral devices are required by the USB specification to support a low power suspend state. Self powered peripheral devices and hosts set their own power management strategies based on their system level requirements. The clocking architecture selected is important to consider as it determines what portions of the design will remain active when transitioned into the low power state.

Before the system clock is suspended or set to a frequency that is below the operational frequency of the USB-HS core, the core must be moved from the operational state to a low power state. The power strategies designed into the USB-HS core allow for the most challenging case, a self powered device that is clocked entirely by the transceiver clock.

### 9.2 Device power states

A bus powered peripheral device must move through the power states as directed by the host. Optionally autonomously directed low power states may be implemented.

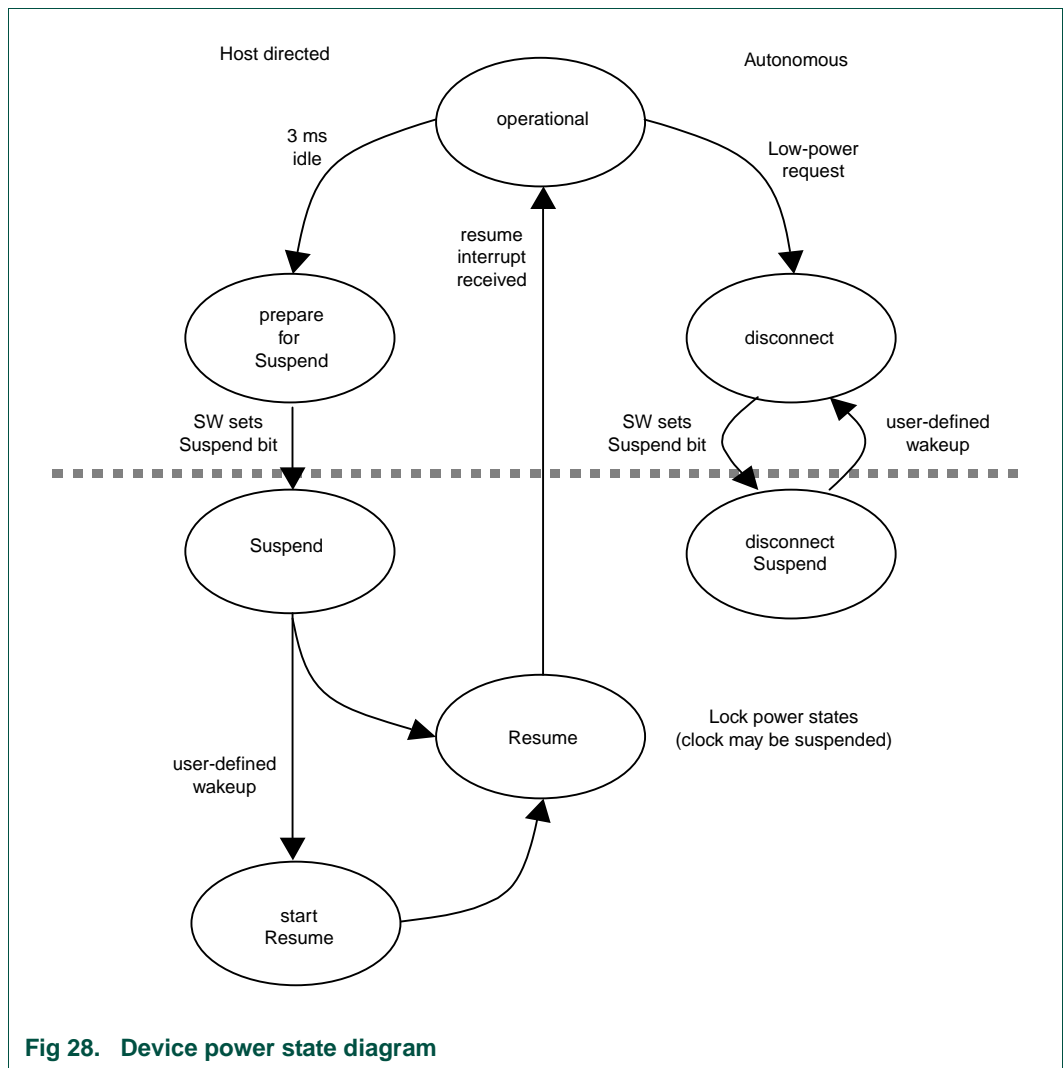

Fig 28. Device power state diagram

In the operational state both the transceiver clock and system clocks are running. Software can initiate a low power mode autonomously by disconnecting from the host to go into the disconnect state. Once in this state, the software can set the Suspend bit to

turn off the transceiver clock putting the system in to the disconnect-suspend state. Since software cannot depend on the presents of a clock to clear the Suspend bit, a wakeup event must be defined which would clear the Suspend bit and allow the transceiver clock to resume.

The device can also go into suspend mode as a result of a suspend command from the host. Suspend is signaled on the bus by 3ms of idle time on the bus. This will generate a suspend interrupt to the software at which point the software must prepare to go into suspend then set the suspend bit. Once the Suspend bit is set the transceiver clock may turn off and the device will be in the suspended state. The device has two ways of getting out of suspend.

1. If remote wake-up is enabled, a wakeup event could be defined which would clear the Suspend bit. The software would then initiate the resume by setting the Resume bit in the port controller then waiting for a port change interrupt indicating that the port is in an operational state.
2. If the host puts resume signaling on the bus, it will clear the Suspend bit and generate a port change interrupt when the resume is finished.

In either case the system designer must insure an orderly restoration of the power and clocks to the suspended circuitry.

9.3 Host power states

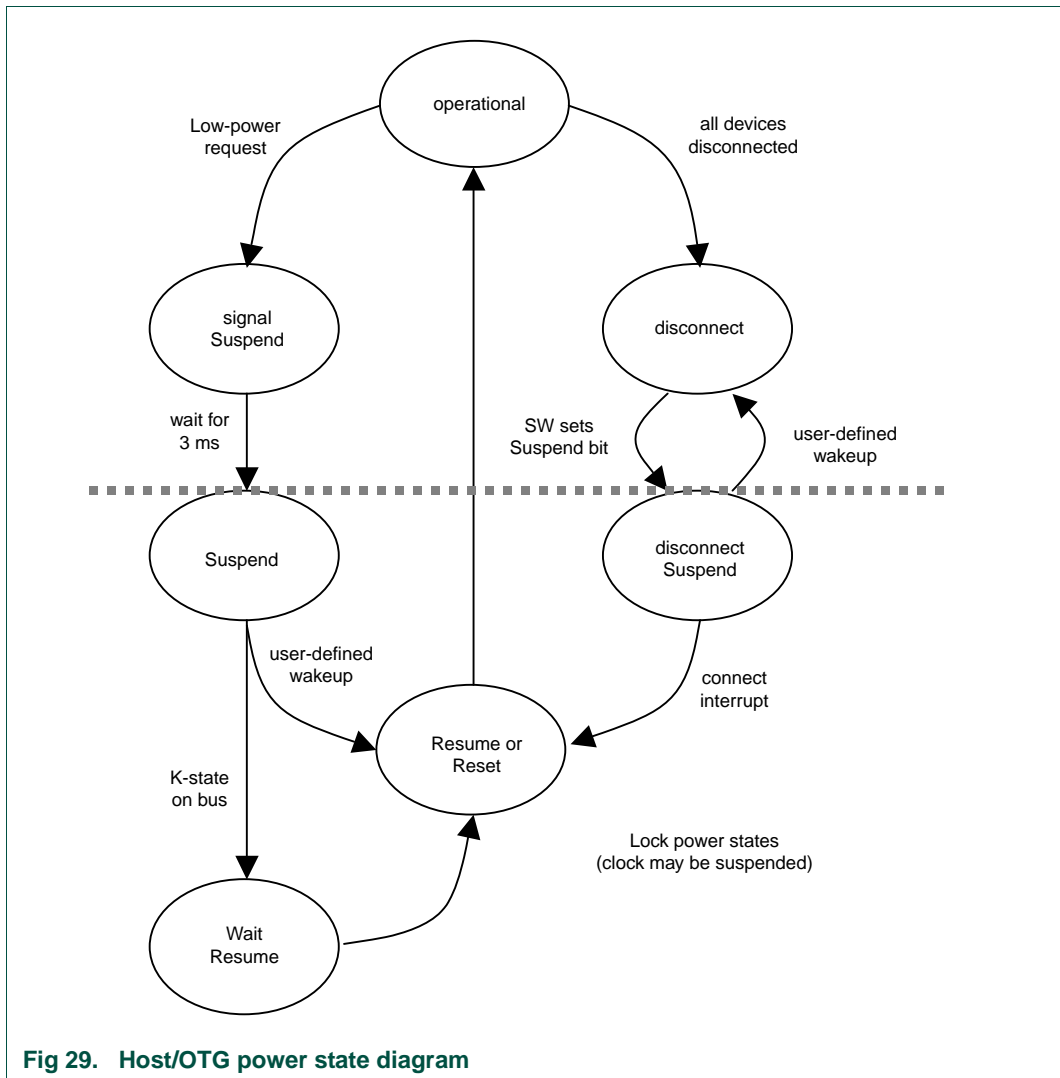

Fig 29. Host/OTG power state diagram

From an operational state when a host gets a low power request, it must set the suspend bit in the port controller. This will put an idle on the bus, block all traffic through the port, and turn off the transceiver clock. There are two ways for a host controller to get out of the suspend state. If it has enabled remote wake-up, a K-state on the bus will turn the transceiver clock and generate an interrupt. The software will then have to wait 20 ms for the resume to complete and the port to go back to an active state. Alternatively an external event could clear the suspend bit and start the transceiver clock running again. The software can then initiate a resume by setting the resume bit in the port controller, or force a reconnect by setting the reset bit in the port controller.

If all devices have disconnected from the host, the host can go into a low power mode by the software setting the suspend bit. From the disconnect-suspend state a connect event would start the transceiver clock and interrupt the software. The software would then need to set the reset bit to start the connect process.

## 9.4 Susp\_CTRL module

The SUSP\_CTRL module implements the power management logic of USB-OTG. It controls the suspend input of the transceiver. Asserting this suspend signal will put the transceiver in suspend mode and the generation of the 30 MHz clock and 60 MHz clock will be switched off.

A suspend control input of the transceiver (`otg_on`) that was previously tied high and prevented the transceiver to go into full suspend mode, has been connected to bit 0 of the `USB_OTG_CFG` register in the SYSCREG module (see [Table 27-544](#)). This bit is low by default and only needs to be set high in OTG Host mode operation.

In suspend mode, the transceiver will raise an output signal indicating that the PLL generating the 480 MHz clock can be switched off.

The SUSP\_CTRL module also generates an output signal indicating whether the AHB clock is needed or not. If '0' the AHB clock is allowed to be switched off or reduced in frequency in order to save power.

The core will enter the low power state if:

- Software sets the `PORTSC.PHCD` bit.

When operating in host mode, the core will leave the low power state on one of the following conditions:

- software clears the `PORTSC.PHCD` bit
- a device is connected and the `PORTSC.WKCN` bit is set
- a device is disconnected and the `PORTSC.WKDC` bit is set
- an over-current condition occurs and the `PORTSC.WKOC` bit is set
- a remote wake-up from the attached device occurs (when USB bus was in suspend)
- the extra external user wake-up input is asserted (active low). This input is controlled by the `USB_OTG_CFG` register in the SYSCREG module (see [Table 27-544](#)).
- a change on `vbusvalid` occurs (= VBUS threshold at 4.4 V is crossed)
- a change on `bvalid` occurs (= VBUS threshold at 4.0 V is crossed).

When operating in device mode, the core will leave the low power state on one of the following conditions:

- software clears the `PORTSC.PHCD` bit.
- a change on the USB data lines (`dp/dm`) occurs.
- the extra external user wake-up input is asserted (active low). This input is controlled by a register in the `sys_creg`.
- a change on `vbusvalid` occurs (= VBUS threshold at 4.4 V is crossed).
- a change on `bvalid` occurs (= VBUS threshold at 4.0 V is crossed).

The `vbusvalid` and `bvalid` signals coming from the transceiver are not filtered in the SUSP\_CTRL module. Any change on those signals will cause a wake-up event.

Input signals 'host\_wakeup\_n' and 'dev\_wakeup\_n' are extra external wake-up signals (for host mode and device mode respectively). However the detection of all USB related wake-up events is already handled in the SUSP\_CTRL mode. Therefore in normal situations these signals can be tied high (= inactive).

Important note: it should be noted that the USB PLL cannot generate the required 480 MHz clock when the power supply is 0.9 V. In order to be able to generate 480 MHz, the supply level should be above 1.05 V.

## 1. Introduction

The DMA Controller (DMA) can perform DMA transfers on the AHB bus without using the CPU.

### 1.1 Features

The DMA module supports the following features:

- Supported transfer types:
  - Memory to Memory copy: Memory can be copied from the source address to the destination address with a specified length, while incrementing the address for both the source and destination.
  - Memory to peripheral: Data is transferred from incrementing memory to a fixed address of a peripheral. The flow is controlled by the peripheral.
  - Peripheral to memory: Data is transferred from a fixed address of a peripheral to incrementing memory. The flow is controlled by the peripheral.
- Supports single data transfers for all transfer types.
- Supports burst transfers for memory-to-memory transfers with following constraints:
  - A burst always consists of multiples of 4 (32-bit) words
  - Source and destination address have to be 4 words aligned for burst transfers
- The DMA controller has 12 channels
- Scatter gather possibility. This method is used to gather data which is located at different areas of memory. Two channels are needed per scatter gather action.
- Supports byte, half word and word transfers, and correctly aligns it over the AHB bus.
- Compatible with ARM flow control, for single requests (sreq), last single requests (lsreq), terminal count info (tc) and dma clearing (clr).
- Supports swapping in endianness of the transported data for file reading / MP3 decoding purposes.

**Table 156. Peripherals that support DMA access**

Peripheral name	Supported Transfer Types
NAND-flash controller	Memory to memory. NAND flow control is supported on channel 4 only.
SPI	Peripheral to memory and peripheral to memory
LCD	Memory to peripheral
UART	Memory to peripheral and peripheral to memory
I2C M/S	Memory to peripheral and peripheral to memory
ISRAM/IROM	Memory to memory

Table 156. Peripherals that support DMA access

Peripheral name	Supported Transfer Types
I2SRX_0/1	Peripheral to memory
I2STX_0/1	Memory to peripheral
PCM interface	Memory to peripheral and peripheral to memory

- Will do memory to-memory copies in 2 AHB cycles, and mem to peripheral or peripheral to mem in 3 AHB cycles (When zero waitstates of internal memory).
- Performance increase of burst transfers (with use of internal SRAM) compared to non-burst transfers will be about 30%.
- Contains masks for each IRQ input/source.
- Uses `HPROT` of the AHB bus for buffer disabling for peripheral transfers and the last DMA transfer.
- Most of the Flip-flops of the DMA are static like source, destination, control and length registers. These can be put on a gated clock-domain to conserve power.
- Supports external enabling of DMA channels, so other sources than the CPU can enable one or more DMA channels.
- External enabling possible for NAND flash Controller through channel 4.

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock signals

Table 157. Clock Signals of the DMA Module

Clock Name	Acronym	I/O	Source/ Destination	Description
DMA_PCLK	PCLK	I	CGU	This is the clock the DMA operates on. This is the clock for both the APB and AHB bus.
DMA_CLK_GATED	CLK_GATED	I	CGU	Gated clock of PCLK. This clock is the same as PCLK, but it may be disabled during the inactive periods of the APB bus towards the DMA to reduce power. The clock disabling is done through the CGU, not in the DMA block. Clock gating is done on the active period of PSEL. CLK_GATED has to be synchronous with PCLK.

#### 2.1.2 Bus interface

The DMA module has an APB connection for register access.

The DMA module has a AHB bus connection connected to the multi layer AHB. Through this bus interface, the DMA data transfers are executed.

#### 2.1.3 Interrupt request signals

The DMA module provides one interrupt request signal to the interrupt controller. The interrupt signal indicates when a channel is finished more than half-way, a soft interrupt, or a DMA abort.

### 2.1.4 Reset Signals

The CGU provides a synchronous reset signal to the DMA. It resets the whole DMA.

### 2.1.5 Internal signals of the DMA module

**Table 158. DMA Signals of the DMA Module**

Name	Type	Description
SDMA_SREQ	I	Signals going from DMA slaves, which is used for flow control. 0 = the DMA slave is not ready for single transfer request' 1 = the DMA slave has data available / can accept data.
SDMA_LREQ	I	Signals going from DMA slaves, which is used for flow control. 0 = the DMA slave is not ready for last transfer 1 = the DMA slave has just indicated a last transfer can be performed.
SDMA_TC	O	Signals going to DMA slaves, which is used for flow control. 0 = performed transfer was not the last transfer. 1 = performed transfer was the last transfer.This signal is not used in the LPC315x.
SDMA_CLR	O	If the slave supports DMA flow control, this signal is used to indicate to the slave that the single word / half word / byte transfer is complete, so the slave can restart a the request handshake. 0 = means the transfer is not complete 1 = means the transfer is complete.
SDMA_EXT_ENABLE	I	Signals arriving from external hardware that can also enable a DMA channel. Each bit corresponds to an equivalent SDMA channel. These signals may be generated on a different clock domain.External enabling only flash possible for NAND flash Controller. Channel 4 is used for this.
SDMA_EXT_ENABLE_ACK	O	The acknowledge of the external enabling, when a channels has finished its transfer. Each bit corresponds to a equivalent DMA channel.If this signal will be used on a different clock domain, the receiving side must take care of the clock-crossing. External enabling only possible for NAND flash Controller. Channel 4 is used for this.

### 3. Register overview

**Table 159. Register overview: DMA controller (base address 0x1700 0000)**

Name	R/W	Address Offset	Description
<b>Channel 0 registers</b>			
SOURCE_ADDRESS	R/W	0x000	Source address register of channel 0
DESTINATION_ADDRESS	R/W	0X004	Destination address register of channel 0
TRANSFER_LENGTH	R/W	0X008	Transfer length register for channel 0
CONFIGURATION	R/W	0x00C	Configuration register for channel 0
ENABLE	R/W	0x010	Enable register for channel 0
<reserved>	-	0x014 – 0x018	Reserved
TRANSFER_COUNTER	R/W	0x01C	Transfer counter register for channel 0
<b>Channel 1 registers</b>			
SOURCE_ADDRESS	R/W	0x020	Source address register of channel 1
DESTINATION_ADDRESS	R/W	0X024	Destination address register of channel 1
TRANSFER_LENGTH	R/W	0X028	Transfer length register for channel 1
CONFIGURATION	R/W	0x02C	Configuration register for channel 1
ENABLE	R/W	0x030	Enable register for channel 1

## 4. Register description

### 4.1 Channel registers 0 to 11

**Table 160. SOURCE\_ADDRESS (addresses 0x1700 0000 (channel 0) to 0x1700 0160 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:0	Source address	R/W	0x0	This register contains the address from where the data is read from. This data will remain static during all memory transfers, and can only be changed by re-programming.

**Table 161. DESTINATION\_ADDRESS (addresses 0x1700 0004 (channel 0) to 0x1700 0164 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:0	Destination address	R/W	0x0	This register contains the address to where the data is written to. This data will remain static during all memory transfers, and can only be changed by re-programming.

**Table 162. TRANSFER\_LENGTH (addresses 0x1700 0008 (channel 0) to 0x1700 0168 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:21	-	-	0x0	Reserved
20:0	Transfer length	R/W	0x1FFFFFF	<p>This register contains the amount of cycles to transfer. This can be bytes, half-words or words. This data will remain static throughout the memory transfer, and can only be changed by re-programming.</p> <p>The number of transfers performed is: &lt;The number programmed in this register&gt; + 1</p> <p>If for example 0x100 is programmed in this register, a total of 0x101 transfers will be done. Current maximum is 2048K transfers.</p> <p>Note: If burst transfer is configured in the CONFIGURATION register, than the TRANSFER_LENGTH register will determine the amount of burst transfers. Note: one burst transfer will contain a transfer of 4 words.</p>

If the transfer length programmed is 0 (which means 1 transfer of byte/half word/word/or burst of 4 word), the interrupt halfway is not generated.

Table 163. CONFIGURATION (addresses 0x1700 000C (channel 0) to 0x1700 016C (channel 11))

Bit	Symbol	Access	Reset Value	Description
31:19	-	R	0x0	Reserved
18	CIRCULAR_BUFFER	R/W	0x0	<p>When this bit is set, the enable bit inside the enable register will never be cleared, and the channel will keep looping. However the CPU can still be interrupted at the end of each loop and halfway each loop.</p> <p>This is a good alternative to channel-companions, since this technique requires only one channel to be enabled, saving channels</p>
17	COMPANION_CHANNEL_ENABLED	R/W	0x0	If this bit is set, the channel number programmed inside the copy_companion_channel_n bits will be enabled at the end of the current transfer.
16	-	R	0x0	Reserved
15:13	COMPANION_CHANNEL_NR	R/W	0x0	<p>If the companion_channel_enable bit is set, the channel number programmed in this register will be enabled when the current channel has finished transfer.</p> <p>This allows also the use of a linked-list / scatter-gather method. See <a href="#">Section 9-5.2</a>.</p>
12	INVERT_ENDIANESS	R/W	0x0	<p>0x0: no endianness inversion while transferring</p> <p>0x1: In this setting the endianness of the word, or half-word is switched. This is for instance required for MP3 decoding from PC-files.</p> <p>If the transfer is word aligned, then:            Byte 3 and byte 0 are swapped            Byte 2 and byte 1 are swapped</p> <p>If the transfer is half-word aligned then:            Byte 1 of the half-word is swapped with byte 0</p> <p>Note: It is allowed to use the same source and destination address to change the endianness of the data without copying it to a different location.</p>

**Table 163. CONFIGURATION (addresses 0x1700 000C (channel 0) to 0x1700 016C (channel 11)) ...continued**

Bit	Symbol	Access	Reset Value	Description
11:10	TRANSFER_SIZE	R/W	0x0	<p>This register contains the size of each transfer:</p> <p>0x0: Transfer of words</p> <p>0x1: Transfer of half-words</p> <p>0x2: Transfer of bytes.</p> <p>0x3: Transfer of bursts</p> <p>If half-words or bytes are used, these will be correctly aligned over the AHB bus.</p>
9:5	READ_SLAVE_NR	R/W	0x0	<p>When 0x0 is written to this register, means that the transfer is unconditional for each read, and the read-address is incremented each read-cycle.</p> <p>If a number higher than 0x0 is programmed here, then flow control is used for the status of that specific slave-FIFO pin, decremented by 1. The address is NOT incremented for each write, so the same FIFO is read from each time. Use the pin number listed in <a href="#">Table 9-177</a> to use the flow control of the peripherals.</p> <p>So if a peripheral is connected to pin 3 of the DMA, and flow control for this slave will be used, then 0x4 must be programmed for these bits (0x3 + 1)</p>
4:0	WRITE_SLAVE_NR	R/W	0x0	<p>When 0x0 is written to this register, means that the transfer is unconditional for each write, and the write-address is incremented each write-cycle.</p> <p>If a number higher than 0x0 is programmed here, then flow control for each write is used, checking for the status of that specific slave-FIFO pin, decremented by 1.</p> <p>The address is NOT incremented for each write, so the same FIFO is written each time. Use the pin number listed in <a href="#">Table 9-177</a> to use the flow control of the peripherals.</p> <p>Example: if a peripheral is connected to pin 2 of the DMA, and flow control for this slave must be used, then 0x3 must be programmed (0x2 + 1 = 0x3)</p>

**Table 164. ENABLE (addresses 0x1700 0010 (channel 0) to 0x1700 0170 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:1	-	-	-	Reserved
0	enable	R/W	0	<p>0x0: disable channel.</p> <p>0x1: enable channel.</p> <p>This register will be automatically be disabled when the transfer is finished, OR when the slave has indicated the last transfer using `SDMA_LSREQ`. If the transfer is disabled by the CPU in the middle of a transfer, software might want to reset the counter, by writing to the `TRANSFER_COUNTER` register of that channel. Counter should be reset even if the DMA was stopped because `LSREQ` was active.</p>

**Table 165. TRANSFER\_COUNTER (addresses 0x1700 001C (channel 0) to 0x1700 017C (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:21	-	-	0x0	Reserved
20:0	Transfer Counter	R/W	0x0	<p>Reading this register returns the current counter status of the channel.</p> <p>The counter starts at `0' and ends at the length programmed in the `length' register. When a transfer is finished, the counter is reset to `0'.</p> <p>When a transfer is stopped by a slave, by using the `SDMA_LSREQ' signal, the counter indicates the amount of transfers performed. Writing this register resets the counter to `0'.</p> <p>Example: If this counter reads 0x100, then 0x101 transfers have been performed.</p> <p>Note: If a channel is disabled in the middle of a transfer by the CPU, OR the counter was stopped by using the `SDMA_LSREQ', then writing to this register is the only method of resetting the counter to `0'.</p>

## 4.2 Alternate channel registers 0 to 11

**Table 166. ALT\_SOURCE\_ADDRESS (addresses 0x1700 0200 (channel 0) to address 0x170002B0 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:0	Source address	W	0x0	<p>This register is a mirror of the SOURCE_ADDRESS register, and can only be written to.</p> <p>See <a href="#">Section 9–5.2</a> for more details.</p>

**Table 167. ALT\_DESTINATION\_ADDRESS (addresses 0x1700 0204 (channel 0) to address 0x170002B4 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:0	Destination address	W	0x0	<p>This register is a mirror of the DESTINATION_ADDRESS register, and can only be written to.</p> <p>See <a href="#">Section 9–5.2</a> for more details.</p>

**Table 168. ALT\_TRANSFER\_LENGTH (addresses 0x1700 0208 (channel 0) to 0x1700 02B8 (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:21	-	-	0x0	Reserved
20:0	Transfer Length	W	0x1FFFFFF	<p>This register is a mirror of the TRANSFER_LENGTH register, and can only be written to.</p> <p>See <a href="#">Section 9–5.2</a> for more details.</p>

**Table 169. ALT\_CONFIGURATION (addresses 0x1700 020C (channel 0) to 0x1700 02BC (channel 11))**

Bit	Symbol	Access	Reset Value	Description
31:0	-	W	0x0	This register is a mirror of the CONFIGURATION register, and can only be written to. See <a href="#">Section 9-5.2</a> for more details.

### 4.3 General control registers

**Table 170. ALT\_ENABLE (address 0x1700 0400)**

Bit	Symbol	Access	Reset Value	Description
31:12	-	-	-	reserved
11:0	ALT_CH_EN	R/W	0x0	This register allows enabling and disabling of multiple channels at the same time. Each bit represents a channel number, so Bit 0 = Channel 0 Bit 1 = Channel 1.etc... Please use the individual 'enable' register of each channel, instead of using this register! A read-modify-write to this register might write the wrong data, since there is a chance the enable register of one of the channels has updated itself in between the read-modify-write, because:- it is either finished,- was activated by a 'copy-table' setting,- or when external enabling was involved

The IRQ\_STATUS\_CLR register contains information if a channel has finished its transfer OR if the channel is halfway.

A bit which has been set can only be cleared by writing a '1' to this bit in this register.

The 'finish' bit will only be set when the channel is finished. After clearing, it will only be set again if the channel finishes again.

The 'half-way' bit will only be set when the channel has passed the half of the transfer. After clearing, this bit will only be set when the channels passes halfway again.

The soft interrupt bit will be set when the SOFT\_INT register is written to. This is for scatter-gather interrupt control: The last transfer of a scatter-gather operation can write towards this register, so the CPU knows the scatter-gather operation has finished.

The DMA\_abort bit will be active if any transfer done by the DMA controller resulted in an abort on the AHB bus.

Clearing interrupts: Writing a '1' to a bit will clear the interrupt belonging to that bit.

Table 171. IRQ\_STATUS\_CLR (address 0x1700 0404)

Bit	Symbol	Access	Reset Value	Description
31	DMA_abort			DMA abort
30	Soft_interrupt	R/W	0x0	Soft interrupt, scatter gather
29:24	-	R/W	0x0	reserved
23	Half_way_11	R/W	0x0	Channel 11 is more than half-way
22	Finished_11	R/W	0x0	Channel 11 is finished
21	Half_way_10	R/W	0x0	Channel 10 is more than half-way
20	Finished_10	R/W	0x0	Channel 10 is finished
19	Half_way_9	R/W	0x0	Channel 9 is more than half-way
18	Finished_9	R/W	0x0	Channel 9 is finished
17	Half_way_8	R/W	0x0	Channel 8 is more than half-way
16	Finished_8	R/W	0x0	Channel 8 is finished
15	Half_way_7	R/W	0x0	Channel 7 is more than half-way
14	Finished_7	R/W	0x0	Channel 7 is finished
13	Half_way_6	R/W	0x0	Channel 6 is more than half-way
12	Finished_6	R/W	0x0	Channel 6 is finished
11	Half_way_5	R/W	0x0	Channel 5 is more than half-way
10	Finished_5	R/W	0x0	Channel 5 is finished
9	Half_way_4	R/W	0x0	Channel 4 is more than half-way
8	Finished_4	R/W	0x0	Channel 4 is finished
7	Half_way_3	R/W	0x0	Channel 3 is more than half-way
6	Finished_3	R/W	0x0	Channel 3 is finished
5	Half_way_2	R/W	0x0	Channel 2 is more than half-way
4	Finished_2	R/W	0x0	Channel 2 is finished
3	Half_way_1	R/W	0x0	Channel 1 is more than half-way
2	Finished_1	R/W	0x0	Channel 1 is finished
1	Half_way_0	R/W	0x0	Channel 0 is more than half-way
0	Finished_0	R/W	0x0	Channel 0 is finished

Table 172. IRQ\_MASK (address 0x1700 0404)

Bit	Symbol	Access	Reset Value	Description
31	IRQ DMA abort		0x1	Mask IRQ of DMA abort
30	IRQ of Soft interrupt is masked		0x1	Mask IRQ of Soft interrupt
29:24	-	-	0x0	Reserved

Table 173. TEST\_FIFO\_RESP\_STAT (address 0x1700 0408)

Bit	Symbol	Access	Reset Value	Description
31:0	TEST_FIFO_RESP_STAT	R	0	<p>Test register only.</p> <p>Not useful for functional operation.</p> <p>This register reads out the exact status of the FIFO-response pins going towards the DMA. Bit 30-0 represents the connected SREQ signals. By reading this register, it can be tested if the SREQ pins are correctly connected on a system level.</p>

Table 174. SOFT\_INT (address 0x1700 040C)

Bit	Symbol	Access	Reset Value	Description
31:0	-	-	0	Reserved
0	Enable_soft_interrupt	R/W	0	Writing to this bit will enable the soft_interrupt IRQ, in the IRQ status register. This register exists purely for linked-list, so the last transfer can be a write towards this address. This way the CPU knows exactly when a scatter-gather operation is finished.

## 5. Functional description

### 5.1 Channel arbitration

If the dma contains more than 1 channel (in our case 12 channels), arbitration is required so that each channel gets equal access over the AHB bus.

The channels are checked in a round-robin (circular) motion. First channel 0 receives a transfer, then 1, then 2... then 0 again and so forth.

When the current transfer is finished, the next channel will be checked first. The arbitration goes like this:

```

IF (next channel = enabled)
    IF (mem-to-mem) Current_channel = this channel
    else IF (peripheral to mem) OR (mem to peripheral) OR (peripheral to peripheral)
        If (selected peripheral(s) = ready) Current_channel = this channel
Else IF (next channel + 1 = enabled)
    IF (mem-to-mem) Current_channel = this channel
    else IF (peripheral to mem) OR (mem to peripheral) OR (peripheral to peripheral)
        If (selected peripheral(s) = ready) Current_channel = this channel
Else IF (next channel + 2 = enabled)
Else Current_channel = UNCHANGED

```

A new channel is known within a single clock-cycle. Every new AHB cycle the channels are re-arbitrated. As soon as a channel is ready to start a transfer, this channel gets access, and arbitration will continue from this point.

### 5.2 Scatter gathering / Building a linked-list

Scatter gathering is a method where data is located in lots of different areas of memory and needs to be 'gathered' to one location as a whole. This might be mem to mem, but also mem/peripheral combinations.

In memory, the CPU can program a linked-list which consists of source, destination and length entries. Each entry will be executed as if a channel was programmed by these values and started, in a sequential order.

The dma supports a linked-list by using 2, sequential, channels.

The first channel will execute the contents of the linked list.

The second channel will perform the updating of the linked list entry.

The way it is implemented in the dma, is that the dma actually re-programs one of its own channels (the previous one), replacing the contents of a channel with the contents of the linked-list, then enables this channel.

A linked-list entry consists of 5 words. The first 4 words reprograms the first DMA channel (the one that executes the contents of the link-list). The fifth word overwrites the source address of the current DMA channel, thus updating the linked list entry to the next location. See the dma register map: the ALT\_addresses.

The fifth word will overwrite the source address of the next channel.

See: [Table 9–175](#)

**Table 175. Linked List Example**

Address	Label	Remark#
n=0: LINKED_LIST_BASE_ADDRESS + n*0x14 + 0x0	Source address n	0
n*0x14 + 0x4	Destination address n	
n*0x14 + 0x8	Transfer Length n	
n*0x14 + 0xc	Configuration n	1
n*0x14 + 0x10	Linked_list_Base_addresses + (n+1)*0x14	Addr next entry
(n+1)*0x14 + 0x0	Source address (n+1)	
(n+1)*0x14 + 0x4	Destination address (n+1)	
(n+1)*0x14 + 0x8	Transfer Length (n+1)	
(n+1)*0x14 + 0xc	Configuration (n+1)	
(n+1)*0x14 + 0x10	Linked_list_Base_addresses + (n+2)*0x14	
-	Room for more entries	2
Last_entry (Method 1). Finish list transfer:		
y=last entry number: (n+y)*0x14 + 0x0	Source address (n+y)	
(n+y)*0x14 + 0x4	Destination address (n+y)	
(n+y)*0x14 + 0x8	Transfer Length (n+y)	
(n+y)*0x14 + 0xc	Configuration (n+y)	Disable companion table option
(n+y)*0x14 + 0x10	0x0	Don't care
Last_entry (Method 2). Implement circular linked list:		
.		
y=last entry number: (n+y)*0x14 + 0x0	Source address (n+y)	
(n+y)*0x14 + 0x4	Destination address (n+y)	
(n+y)*0x14 + 0x8	Transfer Length (n+y)	
(n+y)*0x14 + 0xc	Configuration (n+y)	
(n+y)*0x14 + 0x10	Linked_list_Base_addresses	Jump to the start of the linked list, making it a circular linked list

**Table 175. Linked List Example**

Address	Label	Remark#
Last_entry (Method 3). Generate soft interrupt at the end of transfer:		
y=last entry number: (n+y)*0x14 + 0x0	<Any readable memory address>	3
(n+y)*0x14 + 0x4	<dma SOFT_INT address>	4
(n+y)*0x14 + 0x8	0x1	5
(n+y)*0x14 + 0xC	0x0	6
(n+y)*0x14 + 0x10	0x0	Don't care
Last_entry (Method 4). Generate soft interrupt and also disentangle the companion channels.		
y=last entry number: (n+y-1)*0x14 + 0	<Any readable memory address>	3
(n+y-1)*0x14 + 0x4	<dma SOFT_INT address>	4
(n+y-1)*0x14 + 0x8		
0x1		5
(n+y-1)*0x14 + 0xC	<word transfer + Enable_next_table>	7
(n+y-1)*0x14 + 0x10	Linked_List_Base_address	Addr last entry s + (n+y)*0x14
y=last entry number: (n+y)*0x14 + 0x0	Source address y	
(n+y)*0x14 + 0x4	Destination address y	
(n+y)*0x14 + 0x8	Transfer Length y	
(n+y)*0x14 + 0xc	Configuration y	Disable companion table option
(n+y)*0x14 + 0x10	0x0	Don't care

**Remark:** 0: n = Channel entry number.

**Remark:** 1: The configuration register can be programmed any way the programmers likes it, but should always have the `companion channel' set to the next channel, or otherwise the linked-list execution stops. An exception in this case is when the programmer wants to stop the linked list execution (for instance in case of the last entry)

**Remark:** 2: As many entries can be set here as the programmer would like, each entry consuming 20 bytes of local memory. Remember that every entry has 5 addresses, and that address 5 contains the address of the following entry.

**Remark:** 3: This last entry will soft-interrupt the DMA controller, so the CPU knows the last transfer has finished. The source address is `don't care', but preferably a memory mapped location (like SRAM).

**Remark:** 4: The destination address is the soft-interrupt register of this DMA controller.

**Remark:** 5: Length `1' is sufficient

**Remark:** 6: This setting disables companion-channels, so basically this is the last transfer.

**Remark:** 7: The 'enable companion channel' option must be set, since there is still 1 transfer left.

**5.2.1 Ending a linked-list transfer inside the linked list**

The last entry of a linked list is a special one. In the example linked-list, there are 4 methods described how to end the linked list transfer:

**Method 1** - Just stop the linked list, by disabling the copy-table-enabling in the config setting.

This can be done for instance if the CPU is not interested in an IRQ on this event.

**Method 2** - Re-start the linked list by pointing the last pointer back to the beginning of the linked list, effectively creating a circular buffer made out of linked list entries.

**Method 3** - Write towards the DMA soft interrupt register, which enables the CPU to be interrupted, so that it can act on the event that a linked-list has ended.

**Method 4** - This is a combination of 1 and 3. Now the CPU gets a soft interrupt 1 entry before the last entry is executed.

**Method x** - Whatever suits the application.

**5.2.2 To start a linked-list operation**

- Program into memory the linked-list to <linked-list\_base\_address>.
- Reserve 2 sequential DMA channels/channels.
- Program the second channel as follows:

**Table 176. Linked List Example**

Source Address	<Linked_list_base_address>
Destination address	<The alternative source address of the previous DMA channel>
Transfer Length	0x4 (for 5 addresses per entry)
Configuration	DMA_word + enable_companion_channel (previous channel)
Enable address	0x1 (start the transfer)

**Remark:** Please make sure that the ALT\_SOURCE\_REG is used as the destination address, and not the normal SOURCE\_REG.

**5.2.3 Ending a linked list transfer in the middle of a linked-list execution**

There may be cases where the CPU needs to stop a linked-list from execution. There are more ways to do this:

1. Brutally stop the execution. This can be done by:
  - Enable [first\_channel]=0
  - Enable [second\_channel]=0
  - Enable [first\_channel]=0

Now both channels are disabled, and the execution is stopped.

To continue, do the following:

```
if counter[first_channel] > 0 then
    Enable[first_channel] = 1
else
    Enable[second_channel] = 1
```

2. Stop the linked-list, but let the current entry finish first.
3. This can be done by read-modify-write the config[second\_channel] register, and disable the 'companion channel' bit.
4. When this is done, the linked list entry will finish, and a new linked-list entry will be programmed in the previous channel.
5. However, the first channel will not be enabled, thus stopping the transfer.
6. To continue, do the following:
  - read-modify-write the config[second\_channel] register, and enable the 'companion channel' bit.
  - enable[first\_channel] = 1

### 5.3 DMA flow control

The DMA flow control is compatible to the ARM flow control used in the ARM PL080 and PL081 DMA controllers.

Not supported by the DMA is the 'Burst Request' and 'Last Burst Request' signal, if this signal indicates a burst of more than one word.

For information about the timing of the DMA flow control, please refer to the ARM PL080 data sheet.

Is allowed for DMA slaves to assert an asynchronous request signal, either slower or faster than the DMA clock. This is synchronized inside the DMA. Please take care that the slave may receive an asynchronous 'DMA\_CLR' signal as well, if there is an intention to use asynchronous clocks.

If a DMA slave is behind a write-buffered bridge or has its own write buffer, this DMA slave may only de-assert 'SREQ' when the transfer is truly completed. If the slave does not comply to this rule, then the write-buffered bridge must support the disabling of the write-buffer by reading the AHB-HPROT[2] signal.

Extra flip-flops are added for the Flow Control signals. This is needed for synchronization between blocks, which run on an other frequency than the DMA.

## 5.4 Connectivity

Table 177. SOFT\_INT

Module	DMA Source	Peripheral Pin <sup>[1]</sup>	Interrupt
IPINT/PCM	lpint_tx	0	IP_int tx single request indication
	lpint_rx	1	IP_int0 rx single request indication
UART	uart_rx	2	UART rx receive FIFO request information
	uart tx	3	UART tx transmit FIFO request information
I2C0	I2c0	4	i2c0 FIFO DMA request
I2C1	I2c1	5	i2c1 FIFO DMA request
I2STX0	I2STX0_dma_req_left	6	I2STX0 Left channel DMA request
	I2STX0_dma_req_right	7	I2STX0 Right channel DMA request
I2STX1	I2STX1_dma_req_left	8	I2STX1 Left channel DMA request
	I2STX1_dma_req_right	9	I2STX1 Right channel DMA request
I2SRX0	I2SRX0_dma_req_left	10	I2SRX0 left channel DMA request
	I2SRX0_dma_req_right	11	I2SRX0 right channel DMA request
I2SRX1	I2SRX1_dma_req_left	12	I2SRX1 left channel DMA request
	I2SRX1_dma_req_right	13	I2SRX1 right channel DMA request
-	-	14	reserved
-	-	15	reserved
LCD interface	lcd_interface_dma_req	16	LCD interface FIFO transmit DMA request
SPI	spi_tx_dmareq	17	SPI dma request for transmitting data.
	spi_rx_dmareq	18	SPI dma request for receiving data.
SD/MMC	sd_mmc_dmasreq	19	SD_MMC dma request for transmitting/receiving data.

[1] When programmed, add `0x1' to this number.

### 5.4.1 Using FIFO level slaves, which have no flow control

The DMA can support FIFO level slaves, with the following rules:

- For a FIFO level slave which is read, the FIFO level must be updated directly after the read has taken place.
- For a FIFO level slave which is written, the FIFO level must be updated directly after the write has taken place. If a write-slave is behind a write-buffered bridge, then the write-buffered bridge must support the disabling of the write-buffer by reading the AHB-HPROT[2] signal. If this is not done, it is then possible that the DMA sometimes performs two transfers to the slave in stead of one. This may be acceptable for a slave, but it is then mandatory the FIFO of this slave can accept two transfers. The DMA will never exceed its maximal transfer count.
- On top-level connectivity, the FIFO level request signal must be ANDed with the inverted DMA\_CLR[x] signal. This new signal is then connected to the same numbered DMA\_SREQ[x] pin.

## 5.5 External enable flow control

Other devices than the CPU can enable a DMA channel by activating one of the 'Ext\_Enable' flow control pins.

The DMA has an equal number of these pins available on the DMA top-level as there are channels available, and each external enable pin-number has a direct connection to its equivalent DMA channel number. The activation of one of these pins immediately enables its corresponding DMA channel.

So:

- Ext\_en[0] can enable channel 0;
- Ext\_en[1] can enable channel 1;
- Ext\_en[2] can enable channel 2;
- Ext\_en[3] can enable channel 3;
- Ext\_en[4] can enable channel 4;
- Ext\_en[5] can enable channel 5;
- Ext\_en[6] can enable channel 6;
- Ext\_en[7] can enable channel 7;
- Ext\_en[8] can enable channel 8;
- Ext\_en[9] can enable channel 9;
- Ext\_en[10] can enable channel 10;
- Ext\_en[11] can enable channel 11;

**Table 178. Connections to DMA EXT\_EN Pins**

Ext_en	Connected Device
0	-
1	-
2	-
3	-
4	NAND flash_ctrl_DMA_ext_enable
5	-
6	-
7	-
8	-
9	-
10	-
11	-

It uses the following flow control, using Ext\_en[4] as an example:

Ext\_en[4] is asserted by the NAND flash Controller

The DMA starts channel 4 because of this assertion.

Ext\_en[4] must remain asserted until Ext\_en\_ack[4] is asserted by the DMA.

The DMA asserts Ext\_en\_ack[4], when channel 4 is finished with all its transfers.

Ext\_en[4] can be de-asserted.

The DMA will de-assert Ext\_en\_ack[4] because of this.

Another transfer is allowed, and the flow may be restarted.

A DMA channel can only be enabled by this method, not disabled.

If `Ext\_en[4]` is asserted, the DMA will only enable channel 4 once. If the transfer is complete, and Ext\_en[4] remains asserted, channel 4 will remain inactive. So a toggle is required on Ext\_en[4] before multiple enables are possible, and this has to be done according the Ext\_en flow control as described above.

It is allowed to have the `Ext\_en` signals on different clock domains, so the NANDflash Controller can run faster or slower than the DMA

The `Ext\_en\_ack` of a channel is always asserted for at least a single clock-cycle if that channel is finished, disregarding if Ext\_en is asserted or not. Any peripheral can recognize this way if a channel is finished.

## 6. Power optimization

---

Further more the module has clock gating. The gated clock CLK\_GATED is requested when necessary. This will be requested as long as there is a transfer going on at the APB bus to/from the DMA. Setting the external enabling bit of PCR CGU registers of this clock, enables the clock gating of the this clock.

## 1. Introduction

---

The Interrupt Controller (INTC) collects interrupt requests from multiple devices, masks interrupt requests, and forwards the combined requests to the processor (see [Figure 10–30](#)). The interrupt controller also provides facilities to identify the interrupt requesting devices to be served.

This module has the following features:

- The interrupt controller decodes all the interrupt requests issued by the on-chip peripherals.
- Two interrupt lines (nFIQ, nIRQ) are provided to the to the ARM core. The ARM core supports two distinct levels of priority on all interrupt sources, nFIQ for high priority interrupts and nIRQ for normal priority interrupts.
- Software interrupt request capability associated with each request input.
- Visibility of the interrupt's request state before masking.
- Support for nesting of interrupt service routines.
- Interrupts routed to nIRQ and to nFIQ are vectored.

The following blocks can generate interrupts:

- Nand flash controller
- USB 2.0 HS OTG
- Event router
- 10-bit ADC
- UART
- LCD
- SPI
- I2C Master/Slave 0 and I2C Master/Slave 1
- Timer0, Timer1, Timer2, and Timer3
- I2STX\_0/1
- I2SRX\_0/1
- DMA

## 2. General description

---

The Vectored Interrupt Controller (INTC) collects interrupt requests from multiple devices, masks interrupt requests, and forwards the combined requests to the processor (see [Figure 10–30](#)). The interrupt controller also provides facilities to identify the interrupt requesting devices to be served.

The interrupt controller decodes all the interrupt requests issued by the on-chip peripherals. It supports total 29 interrupt sources and has two outputs (nFIQ, nIRQ). The ARM core can have two distinct levels of priority on all interrupt sources, nFIQ higher priority and nIRQ has lower. The interrupt controller shall operate as AHB slave.

Common features are:

- Software interrupt request capability associated to each request input
- Visibility of interrupt request state before masking
- Support for nesting of interrupt service routines.

Interrupts routed to nIRQ and to nFIQ are vectored. That is to say that the processor can execute the interrupt handler corresponding to the current interrupt without testing each interrupt individually. Thus the software is minimized.

The interrupt vector register contains the index of a specific ISR and an associated priority limiter value can be delivered if nesting of ISR is to be done.

In this interrupt controller, a set of software accessible variables is provided to control interrupt request generation. It is essentially used in debug mode.

The interrupt controller supports interrupts, which are level sensitive, asynchronous and can be active low or high.

## 2.1 Interface description

### 2.1.1 Clock signals

Table 179. Clock signals of the INTC module

Clock Name	Acronym	I/O	Source/ Destination	Description
INTC_CLK	CLK	I	CGU	Main clock; identical to AHB CLK

### 2.1.2 Interrupt request signals

The LPC315x interrupt controller supports 29 interrupt lines as asynchronous interrupt requests from interrupt devices (level active, any polarity). The INTC provides two outputs (level active low) to the ARM processor.

#### 2.1.2.1 Processor Interrupt Request Inputs

The 29 interrupt request input signals are level active (of any polarity) and assumed glitch-free. They are treated as asynchronous to the interrupt controller clock INT\_CLK. Interrupt requests once asserted, must be kept asserted until served by a software ISR.

#### 2.1.2.2 Processor Interrupt Request Outputs

Processor interrupt requests are provided as level active output signals glitch-free at both polarities. Once asserted, processor interrupt request signals stay asserted until the interrupt device removes the request or the request becomes masked due to some state change of interrupt controller variables.

The interrupt controller introduces an interrupt latency (measured from assertion of an interrupt request signal to an assertion of interrupt signal to the CPU of less than 2 clk periods.

### 2.1.3 Reset signals

Table 180. Reset signals of the INTC module

Name	Type	Description
DTL_MMIO_RST_AN	I	Reset

The interrupt controller gets as an input a fully asynchronous reset signal (rst\_an), which is internally synchronized to INT\_CLK. The state of interrupt controller and bus adapter is initialized synchronous to clk. The minimum period of active reset (rst\_an = 0) is 1 clk period.

### 2.1.4 DMA transfer signals

INTC block does not have any interface with the DMA block for DMA functionality. However, there is an interrupt request signal coming from DMA controller, which is one of the total 29 interrupts the INTC block receives.

## 2.2 Available interrupts

Table 181. Available Interrupts

Module	Interrupt Source	Interrupt Number	Interrupt
Event Router	CASCADED_IRQ_0	1	Event Router IRQ0
	CASCADED_IRQ_1	2	Event Router IRQ1
	CASCADED_IRQ_2	3	Event Router IRQ2
	CASCADED_IRQ_3	4	Event Router IRQ3
TIMER0	TIMER0_INTCT	5	Count INT Timer0
TIMER1	TIMER1_INTCT	6	Count INT Timer1
TIMER2	TIMER2_INTCT	7	Count INT Timer2
TIMER3	TIMER3_INTCT	8	Count INT Timer3
ADC 10 Bit	ADC_INT	9	ADC INT
UART	UART_INTREQ	10	RECEIVER ERROR FLAG
			RECEIVE DATA AVAILABLE
			TIME-OUT
			TRANSMIT HOLDING EMPTY
			TRANSMIT DONE
			TRANSMIT ARBITRATION FAILURE
			TRANSMIT NO ACK
			MASTER TRANSMITTER DATA REQUEST
			SLAVE TRANSMITTER DATA REQUEST
			RECEIVE FIFO FULL
RECEIVE DATA AVAILABLE			
TRANSMIT FIFO NOT FULL			
SLAVE TRANSMIT FIFO NOT FULL			

Table 181. Available Interrupts

Module	Interrupt Source	Interrupt Number	Interrupt
I2C1 Master/Slave	I2C1_NINTR	12	TRANSMIT DONE
			TRANSMIT ARBITRATION FAILURE
			TRANSMIT NO ACK
			MASTER TRANSMIT DATA REQUEST
			SLAVE TRANSMITTER DATA REQUEST
			RECEIVE FIFO FULL
			RECEIVE DATA AVAILABLE
			TRANSMIT FIFO NOT FULL
			SLAVE TRANSMIT FIFO NOT FULL
			I2S Subsystem
I2STX1_IRQ	14	I2S1 TRANSMIT INTERRUPT	
I2SRX0_IRQ	15	I2S0 RECEIVE INTERRUPT	
I2SRX1_IRQ	16	I2S1 RECEIVE INTERRUPT	
reserved	17	-	
LCD INTERFACE	LCD_INTERFACE_IRQ	18	LCD FIFO EMPTY
			LCD FIFO HALF EMPTY
			LCD FIFO OVERRUN
			LCD READ VALID
SPI	SPI_SMS_INT	19	SPI SMS
	SPI_TX_INT	20	SPI Transmit
	SPI_RX_INT	21	SPI Receive
	SPI_OV_INT	22	SPI OV
	SPI_INT	23	SPI Interrupt
DMA	DMA_IRQ	24	DMA DATA TRANSFER COMPLETE
NANDFLASH CTRL	NANDFLASH_CTRL_IRQ_NAND	25	NANDFLASH CTRL Interrupt
MCI	SD_MMC_INTR	26	MCI Interrupt
USB OTG	USB_OTG_IRQ	27	USB OTG Interrupt
ISRAM0	ISRAM0_MRC_FINISHED	28	ISRAM0 Interrupt
ISRAM1	ISRAM1_MRC_FINISHED	29	ISRAM1 Interrupt

In the above table, for UART, I2C0, I2C1 and LCD-Interface modules, any one or more of the multiple sources (4th column) can cause the interrupt (2nd column) shared by them, as they are assigned to that single interrupt bit. The exact source which caused the interrupt can be distinguished by reading the appropriate bits from registers inside the module. To find these details, please refer to the chapters for these specific modules.

### 2.3 Block diagram

Fig 30. Interrupt controller block diagram

### 2.4 Short Description of sub blocks

#### 2.4.1 Input Stage

An input stage performs the following tasks (see [Figure 10–30](#)):

- Input of one interrupt request (intreq) signal
- Latch the interrupt request state during computation of the interrupt vector, otherwise keep the latch transparent
- Invert the request polarity if the interrupt request signal is active low (controlled by the variable `ACTIVE_LOW`),
- Combine the interrupt request with the state of a local software interrupt request variable

- Enable or disable the resulting interrupt request (controlled by variable ENABLE), and finally
- Forward the request to the priority masking stage together with attributes characterizing the interrupt request. These attributes are: - the priority level assigned to the request (variable PRIORITY\_LEVEL) - the interrupt target defined for the request (variable TARGET).

In addition, the input stage provides means to set and clear the software interrupt request variable (SET\_SWINT and CLR\_SWINT commands) and to observe the request status before priority masking (variable PENDING).

While no interrupt vector is being computed, the signal path of an interrupt request throughout the input stage (including the latch) is asynchronous and requires no active interrupt controller clock. Immediately before vector computation the latch synchronously captures the state of the intreq line and thereby blocks any signal changes to propagate into the vector stage potentially leading to incorrect index computation. Sufficient time to resolve potential metastability of the latched request will be allowed. After vector computation, the latch becomes transparent again.

There is one input stage per interrupt request input. The number of input stages is from 1 to 29 (see [Table 10–181](#)). The vector stage references an input stage through an index. There is no input stage defined for index 0 as this index is reserved for a special purpose by the vector stage.

#### 2.4.2 Priority Masking Stage

The priority masking stage performs the following tasks:

- For each of the 2 interrupt targets, input all interrupt requests selected for the target and mask pending interrupts which are at lower or equal priority than a target specific priority threshold (PRIORITY\_LIMITER)
- For each of the 2 interrupt targets, combine pending interrupt requests with priority above the priority threshold through a logical OR and route the result towards the interrupt target.

The signal path of interrupt requests throughout the priority masking stage towards the output stage is asynchronous and requires no active interrupt controller clock.

#### 2.4.3 Output Stage

The output stage performs the following tasks:

- For each interrupt target, produce processor interrupt request output signals `cpuintr{0..1}{_n}` at both active high and low level by registering the interrupt request information of the priority masking stage.

The interrupt controller introduces an interrupt latency (measured from assertion of an intreq. signal to an assertion of `cpuintr{0..1}{_n}`) of less than 2 clock periods.

#### 2.4.4 Vector Stage

The vector stage provides one vector register per interrupt target (`INT_VECTOR_{0...1}`). It performs the following tasks triggered by a read action to one of these registers:

- For a read of register INT\_VECTOR\_t, process the PRIORITY information of input states with pending interrupt requests selected for TARGET = t,
- Then identify the input stage with the highest PRIORITY value above the target specific PRIORITY\_LIMITER threshold (if this condition is true for a multitude of input stages, then the input stage with the highest index is taken), and finally
- Present the index of that input stage through the INDEX variable in the INT\_VECTOR\_t register. If no interrupt request exceeds the PRIORITY\_LIMITER threshold, then INDEX=0 is given.

The above process is performed upon any INT\_VECTOR\_\* read action - there is no storage of a previously computed vector.

The information from the INT\_VECTOR\_\* register facilitates a generic software ISR in identifying the interrupt requesting device to be serviced. To invoke the ISR of that device, the INDEX variable can be taken as offset into a table of address pointers towards device specific ISR. Alternatively, the total content of the INT\_VECTOR\_\* register, consisting of a table base address (variable TABLE\_ADDR) plus INDEX, can be taken as pointer into a table.

INDEX = 0 identifies the special case that no interrupt request requires service when the INT\_VECTOR\_\* register is read.

For correct vector computation, it is required that the ISR always reads the INT\_VECTOR\_\* register that corresponds to the interrupt target.

If 2 interrupts with same priority get activated at the same time, then the interrupt with lower identity number (see [Table 10–181](#)) takes priority.

### 3. Register overview

The purpose of the control interface is to give a processor read and write access to internal registers of the interrupt controller.

When reading one of the INT\_VECTOR\_{0...T} registers, then read access time is extended in respect to read access time of other registers by 2 additional wait cycles. This extra wait time covers the needs of vector computation and meta-stability resolution on latched intreq. signals even at maximum clk frequency.

**Table 182. Register overview: Interrupt controller (base address 0x6000 0000)**

Name	R/W	Address offset	Description
INT_PRIORITYMASK_0	R/W	0x000	interrupt target 0 priority threshold
INT_PRIORITYMASK_1	R/W	0x004	interrupt target 0 priority threshold
INT_VECTOR_0	W	0x100	Vector register for target 0 => nIRQ
INT_VECTOR_1	R/W	0x104	Vector register for target 1 => nFIQ
INT_PENDING_1_31	W	0x200	status of interrupt request 1..29 (3 bits don't care)
INT_FEATURES	R/W	0x300	interrupt controller configuration features

## 4. Register description

### 4.1 Interrupt Priority Mask Register

Table 183. INT\_PRIORITYMASK register (INT\_PRIORITYMASK 0, address 0x6000 0000 and INT\_PRIORITYMASK1 address 0x6000 0004)

Bit	Symbol	Access	Reset Value	Description
[31:8]	inter_slave_dly	Reserved	X	Reserved for future extensions; should be written as 0
[7:0]	PRIORITY_LIMITER	R/W	X	Priority Limiter: this variable determines a priority threshold that incoming interrupt requests must exceed to trigger interrupt requests towards processor. See text below.

Legal PRIORITY\_LIMITER values are 0 ... 15; other values are reserved and lead to undefined behavior.

PRIORITY\_LIMITER = 0: incoming interrupt requests with priority >0 can trigger interrupt requests towards processor.

PRIORITY\_LIMITER = n: only interrupt requests at a priority level above n can trigger interrupt requests towards processor.

PRIORITY\_LIMITER = 15: no incoming interrupt requests can trigger interrupt requests towards processor.

The PRIORITY\_LIMITER variable can be used to define the minimum priority level for nesting interrupts: typically, the PRIORITY\_LIMITER variable is set to the priority level of the ISR that is currently being executed. By doing this, only interrupt requests at a higher priority level will lead to a nested interrupt service. Nesting can be disabled by setting PRIORITY\_LEVEL = 15 or by disabling interrupt exceptions within the processor.

### 4.2 Interrupt Vector Register

These registers identify, individually for each interrupt target, the highest priority enabled pending interrupt request that is present at the time when a register is being read.

**Table 184. INT\_VECTOR registers (INT\_VECTOR0, address 0x6000 0100 and INT\_VECTOR1, address 0x6000 0104)**

Bit	Symbol	Access	Reset Value	Description
31:11	TABLE_ADDR	R/W	X	Table start address: Indicates the lower address boundary of a 2048 byte aligned interrupt vector table in memory
10:3	INDEX	R	X	Index: Indicates the intreq line number of the interrupt request to be served by the processor: INDEX = 0: no interrupt request to be served INDEX = 1: serve interrupt request at input intreq1 INDEX = 2: serve interrupt request at input intreq2 .... INDEX = 29: serve interrupt request at input intreq29
2:0	NULL	R	0	bit field always read as zero

The software ISR must always read the vector register that corresponds to the interrupt target, e.g.:

- read INT\_VECTOR\_0 for interrupt target 0 service. => nIRQ
- read INT\_VECTOR\_1 for interrupt target 1 service. => nFIQ

The INT\_VECTOR\_n register content can be used as a vector into a memory based table. This table has N+1 entries. To be able to use the register content as a full 32 bit address pointer, the table must be aligned to a 2048 byte address boundary. If only the INDEX variable is used as offset into the table, then this address alignment is not required.

Each table entry has 64 bit data. It is recommended to pack per table entry:

the start address of a device specific ISR, plus the associated priority limiter value (if nesting of ISR shall be performed).

64 bit packing will optimize the speed of nested interrupt handling due to caches. In the (likely) case of a cache miss when reading data from the table, the priority limiter value to be programmed into the INT\_PRIORITYMASK register will be loaded into the cache along with the ISR start address, saving several clock cycles interrupt processing time compared to a solution where the priority limiter value would have to be established from an INT\_REQUEST\_\* register.

A vector with INDEX = 0 indicates that no interrupt with priority above the priority threshold is pending. The vector table should implement for this entry a "no interrupt" handler to treat this special case.

**Remark:** Due to the special purpose of INDEX = 0 no interrupt request input intreq0 and thus no INT\_REQUEST\_0 register exists.

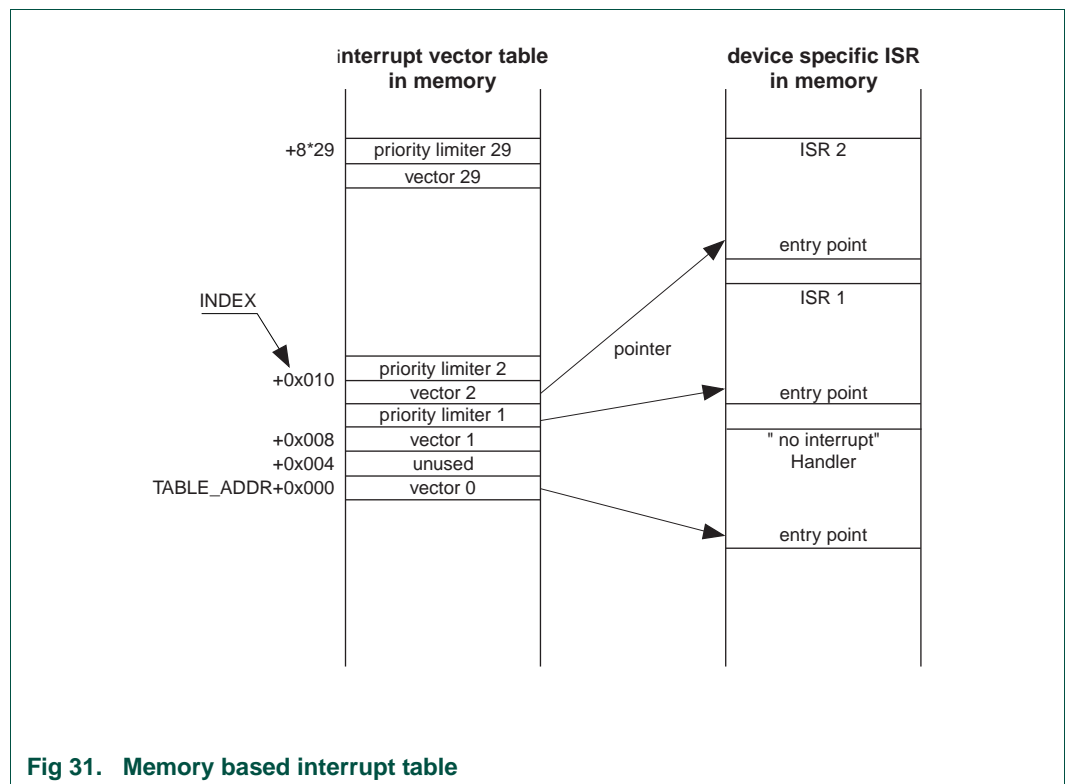

Fig 31. Memory based interrupt table

### 4.3 Interrupt Pending Register

This register gathers the PENDING variables of all interrupt requests.

Software can make use of INT\_PENDING\_1\_31[29:1] register to gain a faster overview on pending interrupt requests than by reading individual INT\_REQUEST\_n registers. For certain software this may lead to a benefit in interrupt processing time.

INT\_PENDING\_1\_31[29:1] reflects the state of signals intreq1...29.

**Table 185. INT\_PENDING register (INT\_PENDING1\_31, address 0x6000 0200)**

Bit	Symbol	Access	Reset	Description
[31:30]	-	R	x	reserved
[29:1]	PENDING[i]	R	X	Pending interrupt request: This variable reflects the state of the intreq[i] line (if needed, converted to active high) OR'ed by the state of the local soft-ware interrupt request variable at the time the register is read. Note that the pending variables are also reflected by the INT_REQUEST_{1..29} registers are present individually for each interrupt request input. PENDING[i] = 0: no interrupt request PENDING[i] = 1: interrupt request is pending
0	-	R	x	reserved

#### 4.4 Interrupt Controller Features Register

This register indicates the hardware configuration parameters chosen during the creation of the interrupt controller. Software can make use of the INT\_FEATURES register to implement interrupt controller configuration specific behavior.

**Table 186. INT\_FEATURES register (address 0x6000 0300)**

Bit	Symbol	Access	Reset Value	Description
31:22	Reserved	R	X	Reserved
21:16	T	R	0x01	IC Configuration parameter T: Number of interrupt targets supported (plus one). This is not configurable by Software, hence is a Read-Only parameter.
15:8	P	R	0x0F	Configuration parameter P: Number of priority levels supported. This is not configurable by Software, hence is a Read-Only parameter.
7:0	N	R	0x26 <sup>[1]</sup>	Configuration parameter N: Number of interrupt request inputs. This is not configurable by Software, hence is a Read-Only parameter.

[1] Although this number indicates 38 interrupt sources, the hardware supports only 29 incoming interrupts as described in rest of the document.

#### 4.5 Interrupt Request Registers

These sets of registers holds configuration information related to interrupt request inputs of the interrupt controller and allows issuing software interrupt requests.

There are 29 interrupt request registers, one for each intreq input signal.

**Table 187. INT\_REQUEST registers (INT\_REQUEST1, address 0x6000 0404 to INT\_REQUEST29, address 0x6000 0474)**

Bit	Symbol	Access	Reset Value	Description
31	PENDING	R	X	<p>Pending interrupt request:</p> <p>This variable reflects the state of the intreq line (if needed, converted to active high) OR'ed by the state of the local soft-ware interrupt request variable at the time the register is read. Note that the PENDING variable is also visible from the INT_PENDING_* registers.</p> <p>PENDING = 0: no interrupt request PENDING = 1: interrupt request pending</p>
30	SET_SWINT	W	0	<p>Set software interrupt request</p> <p>SET_SW_INT = 0 (write): no effect on the state of the local software interrupt request variable</p> <p>SET_SWINT = 1 (write): set the state of the local software interrupt request variable to '1'</p> <p>SET_SWINT is always reads as 0</p>
29	CLR_SWINT	W	0	<p>Clear software interrupt request:</p> <p>CLR_SWINT = 0 (write): clear the state of the local software interrupt request variable to '0'</p> <p>CLR_SWINT is always read as 0</p>
28	WE_PRIORITY_LEVEL	W	X	<p>Write Enable PRIORITY_LEVEL</p> <p>WE_PRIORITY_LEVEL = 0 (write): no change of PRIORITY_LEVEL variable state</p> <p>WE_PRIORITY_LEVEL = 1 (write): PRIORITY_LEVEL variable state may be changed</p> <p>WE_PRIORITY_LEVEL is always read as 0</p>
27	WE_TARGET	W	X	<p>Write Enable TARGET</p> <p>WE_TARGET = 0 (write): no change of TARGET variable state</p> <p>WE_TARGET = 1 (write): TARGET variable state may be changed WE_TARGET is always read as 0</p>
26	WE_ENABLE	W	X	<p>Write Enable ENABLE</p> <p>WE_ENABLE = 0 (write): no change of ENABLE variable state</p> <p>WE_ENABLE = 1 (write): ENABLE variable state may be changed</p> <p>WE_ENABLE is always read as 0</p>

**Table 187. INT\_REQUEST registers (INT\_REQUEST1, address 0x6000 0404 to INT\_REQUEST29, address 0x6000 0474) ...continued**

Bit	Symbol	Access	Reset Value	Description
25	WE_ACTIVE_LOW	W	X	Write Enable ACTIVE_LOW WE_ACTIVE_LOW = 0 (write): no change of ACTIVE_LOW variable state WE_ACTIVE_LOW = 1 (write): ACTIVE_LOW variable state may be changed WE_ACTIVE_LOW is always read as 0
24:18	Reserved	R	X	Reserved; should be written as zeros
17	ACTIVE_LOW	R/W	0	Active Low This variable selects the polarity of the interrupt request input signal. See also WE_ACTIVE_LOW. ACTIVE_LOW = 1: the intreq signal is interpreted as active low ACTIVE_LOW = 0: the intreq signal is interpreted as active high
16	ENABLE	R/W	0	Enable interrupt request This variable controls whether an interrupt request is enabled for further processing by the interrupt controller. See also WE_ENABLE. ENABLE = 0: the interrupt request is discarded. It cannot cause a processor interrupt request. ENABLE = 1: the interrupt request may cause a processor interrupt request when further conditions for this become true.

**Table 187. INT\_REQUEST registers (INT\_REQUEST1, address 0x6000 0404 to INT\_REQUEST29, address 0x6000 0474) ...continued**

Bit	Symbol	Access	Reset Value	Description
15: 14	Reserved	R	X	Reserved; should be written as zeros
13: 8	TARGET	R/W	0	<p>Interrupt target: This variable defines the interrupt target of an interrupt request. Legal values are 0 ... 1; other values are reserved and lead to undefined behaviour. See also WE_TARGET.</p> <p>TARGET = 0: the interrupt request shall lead to a processor interrupt request 0 (cpuint0) =&gt; nIRQ</p> <p>TARGET = 1: the interrupt request shall lead to a processor interrupt request 1 (cpuint1) =&gt; nFIQ</p> <p>High order bits not required for TARGET encoding are read-only 0.</p>
7:0	PRIORITY_LEVEL	R/W	X	<p>Priority level</p> <p>This variable determines the priority level of the interrupt request. Legal values are 0 ... P; other values are reserved and lead to undefined behaviour. See also WE_PRIORITY_LEVEL.</p> <p>PRIORITY_LEVEL = 0: the interrupt request has priority level 0 (masked); it is ignored</p> <p>PRIORITY_LEVEL = 1: the interrupt request has priority level 1 (lowest) ...</p> <p>PRIORITY_LEVEL = 15: the interrupt request has priority level 15 (highest)</p> <p>High order bits not required for PRIORITY_LEVEL encoding are read-only 0</p>

**Remark:** There is no INT\_REQUEST\_0 register.

For changing the TARGET variable state dynamically, software must first disable the interrupt request (ENABLE = 0), then change TARGET and finally re-enable the request (ENABLE = 1).

Write enable commands are provided to allow the modification of individual INT\_REQUEST\_\* variables by simple write operations instead of atomic read-modify-write operations. This feature allows to access INT\_REQUEST\_\* registers simultaneously by multiple software threads.

## 5. Functional description

### 5.1 Why Vectored?

For each incoming interrupt, its source & priority are determined by INTC hardware. Being vectored helps IRQ handler to be simple & quick in response.

## 5.2 Interrupt Targets

The application of interrupt targets is not prescribed by the architecture. It may be specific to a system hardware/software design and may depend on the capabilities of the processor handling the interrupts. The interrupt architecture, as specified by ARM, recommends the following use of interrupt targets:

- ARM processor: target 0 = nIRQ (standard interrupt service with full context state save/restore) target 1 = nFIQ (fast interrupt service with minimal context save/restore)

These recommendations are adapted in the LPC315x hardware also.

The interrupt target is configured for each interrupt request input of the interrupt controller through the TARGET variable in the INT\_REQUEST\_\* registers.

## 5.3 Interrupt Priority

Interrupt request masking is performed individually per interrupt target by comparing the priority level assigned to a specific interrupt request input (variable PRIORITY\_LEVEL in the INT\_REQUEST\_\* registers) with a target specific priority threshold (variable PRIORITY\_LIMITER in the INT\_PRIORITYMASK\_\* registers).

Priority levels are defined as follows:

- Priority level 0 corresponds to 'masked'. Interrupt requests with priority 0 will never lead to an interrupt request towards processor.
- Priority level 1 corresponds to lowest priority.
- Priority level 15 corresponds to highest priority.

Programming the INT\_REQUEST\_\* register variable ENABLE = 0 is an alternative to PRIORITY\_LEVEL = 0 which is typically applied when an interrupt request input shall be temporarily disabled without the need to save and restore the current PRIORITY\_LEVEL setting.

# 6. Power optimization

---

To reduce the power consumption of the interrupt controller, the 'clock gating' option is chosen. With clock gating, the clock for all software accessible registers is provided only during the course of a write operation and during synchronous reset. Outside these conditions, the clock is disabled and internal power dissipation of registers is close to zero.

# 7. Programming guide

---

## 7.1 Software interrupts

Software interrupt support is provided through variables in the INT\_REQUEST\_n registers. Software interrupts can be applied for:

- test the RTOS interrupt handling without using a device specific ISR.
- software emulation of an interrupt requesting device, including interrupts.

## 1. Introduction

The AHB\_TO\_APB is a bus bridge between AMBA Advanced High-performance Bus (AHB) and the AMBA Peripheral Bus (APB).

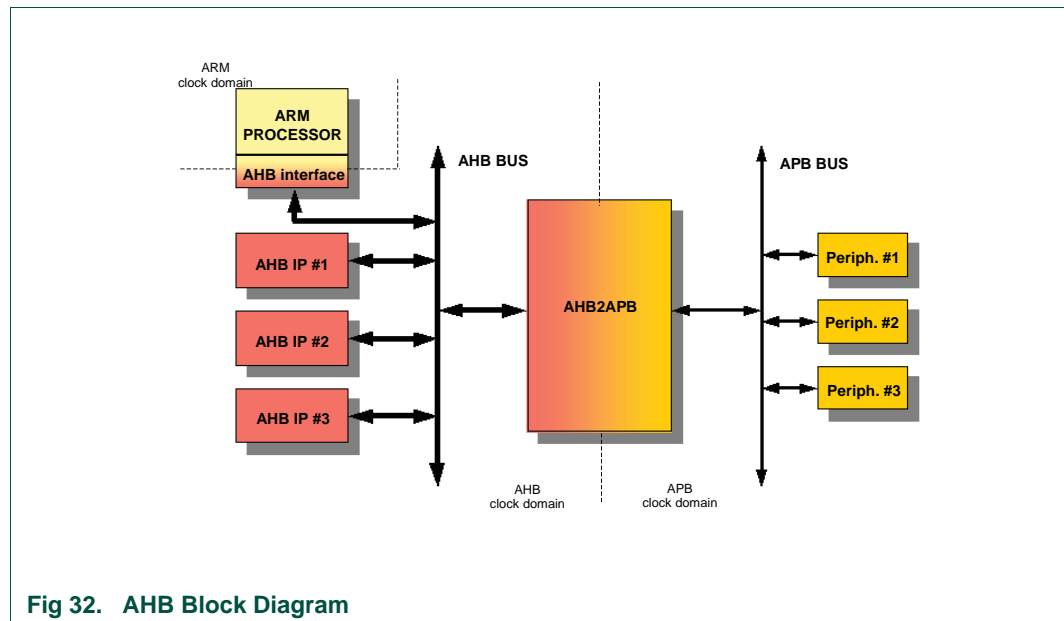

### 1.1 Features

This module has the following features:

- Supports a uni-directional (slave only) APB data bus interface.
- One word deep write buffer.
- Single clock architecture with one clock domain (APB and AHB clock are synchronal). On LPC315x AHB-APB Bridge 4 uses single clock architecture.
- Dual clock architecture with independent AHB and APB clock domains. On LPC315x AHB-APB Bridge 0, AHB-APB Bridge 1, AHB-APB Bridge 2, and AHB-APB Bridge 3 use this architecture.

## 2. General description

### 2.1 Block diagram

The AHB\_TO\_APB Bridge translates bus transactions generated by an AHB master to APB bus transactions. The bridge can de-couple a slow peripheral access by parking the AHB transaction on the bridge and free the high speed/performance AHB bus resource.

## 2.2 Interface description

The AHB\_TO\_APB bridge interface consists of a APB bus interface and a AHB bus interface. The AHB\_TO\_APB bridge has separate and independent clocks and reset signals for the AHB and the APB interface.

The APB interface is connected to the peripheral blocks of the APB subsystem.

The AHB interface is connected to the multi-layer AHB bus.

### 2.2.1 Clock Signals

The LPC315x uses two architecture types of the AHB\_TO\_APB Bridge: a single clock architecture, which has only one clock input, and a dual clock architecture, which has two clocks.

The clocks can be asynchronous i.e. need not have a frequency or phase relation. Because the APB subsystem usually hosts slow peripherals, the APB\_clk frequency is lower than the AHB\_clk frequency.

**Table 188. Clock Signals of the AHB\_TO\_APB**

Clock Name	I/O	Source/ Destination	Description
APB[0:3]_PCLK	I	CGU	Determines the operating frequency of the APB interface of the bridge. Operates the APB interface.
APB[0:4]_CLK	I	CGU	Determines the operating frequency of the AHB interface of the bridge. Operates the AHB interface.

### 2.2.2 Reset signals

The CGU provides two reset signals to the AHB\_TO\_APB bridges: AHB\_RST\_AN, AHB interface global asynchronous reset and APB\_RST\_AN, APB interface global asynchronous reset.

## 3. Register overview

The AHB\_TO\_APB does not have specific configuration registers.

## 4. Detailed architecture and functional modes description

### 4.1 Memory Endianess

The bus bridge operation is independent of the endianess memory format.

### 4.2 Data Steering

Data steering for peripherals that have a narrow data bus (8 or 16 bits) is not supported. These peripherals are assumed to be accessed with word (32-bit) aligned addresses.

Peripherals with sub-word aligned addressing can be connected to the AHB\_TO\_APB Bridge by shifting the address bits. Bits [x:0] of a byte-aligned peripheral must be connected to bits [x+2:2] of the bridge. Bits [x:0] of a half-word (16-bit) aligned peripheral must be connected to bits [x+1:1] of the bridge. In both cases, the master on the AHB side of the bridge (software) must use word aligned addressing.

### 4.3 Write Buffer

The AHB\_TO\_APB Bridge contains a one-word deep write buffer. Any APB device that DOES NOT have a APB\_err signal (like all APB devices) will take advantage of the write buffer provided ahb\_prot is 1, when ahb\_prot is 0 the devices can not use the write buffer. On LPC315x only SPI module generates APB\_err signal. Hence write buffer is used by all other devices/modules connected to APB bus except SPI.

Devices with a APB\_err signal can not use the write buffer. The write buffer alleviates putting wait states on AHB. However, consecutive write access or write-read accesses to the bridge will insert some wait states because the write buffer is only one word deep.

### 4.4 Address Alignment

The AHB\_TO\_APB Bus Bridge allows the user to enter system specifications and information about each of the peripherals connected to the bridge. The address space allocated to each peripheral is described in 'Memory Map' section. The bridge will assign the APB memory map based on these parameters.

## 5. Power optimization

---

The AHB\_TO\_APB module has an asynchronous clock domain crossing, allowing the APB clock frequency to be independent from the AHB clock frequency. This allows power saving by lowering the APB bus frequency while keeping a AHB interface with high clock frequency.

When using the AHB\_TO\_APB you must aim to meet the following guidelines:

- Operate at APB clock speed, when possible.
- Independently from the APB clock, reduce the AHB\_CLK if possible.
- Switch off clocks when the device and its subsystem is not in use.
- Use the bridge write buffer for a more efficient data transfer.

## 6. Programming guide

---

AHB and APB bus clock frequencies can be set and/or disabled via the CGU registers.

## 1. Introduction

---

The multi-layer AHB is an interconnection scheme based on the AHB protocol that enables parallel access paths between multiple masters and slaves in a system. This is achieved by using a more complex interconnection matrix and gives the benefit of increased overall bus bandwidth and a more flexible system architecture.

Multiple masters can have access to different slaves at the same time. When multiple masters want to have access to the same slave, a so called Round-Robin mechanism is used for bus arbitration.

### 1.1 Features

This module has the following features:

- Supports all combinations of 32-bit masters and slaves (fully connected interconnect matrix).
- Round-Robin priority mechanism for bus arbitration: All masters have the same priority and get bus access in their natural order.
- 4 devices on a master port (listed in their natural order for bus arbitration):
  - DMA
  - ARM926 Instruction port
  - ARM926 Data port
  - USB OTG
- 14 slave ports:
  - AHB to APB bridge 0
  - AHB to APB bridge 1
  - AHB to APB Bridge 2
  - AHB to APB Bridge 3
  - AHB to APB Bridge 4
  - Interrupt controller
  - NAND buffer
  - MCI SD/SDIO
  - USB OTG
  - ISRAM0 (96 kB)
  - ISRAM1 (96 kB)
  - ISROM (128 kB)
  - MPMC configuration block
  - MPMC controller
- Zero wait state operation, up to 100% bandwidth usage possible.

- Bus implementation includes address decoding, arbitration and signal mixing.
- Designed to work according to the Multi layer AMBA Advanced System Bus (AHB Lite) concept.

## 1.2 About AHB and multilayer AHB

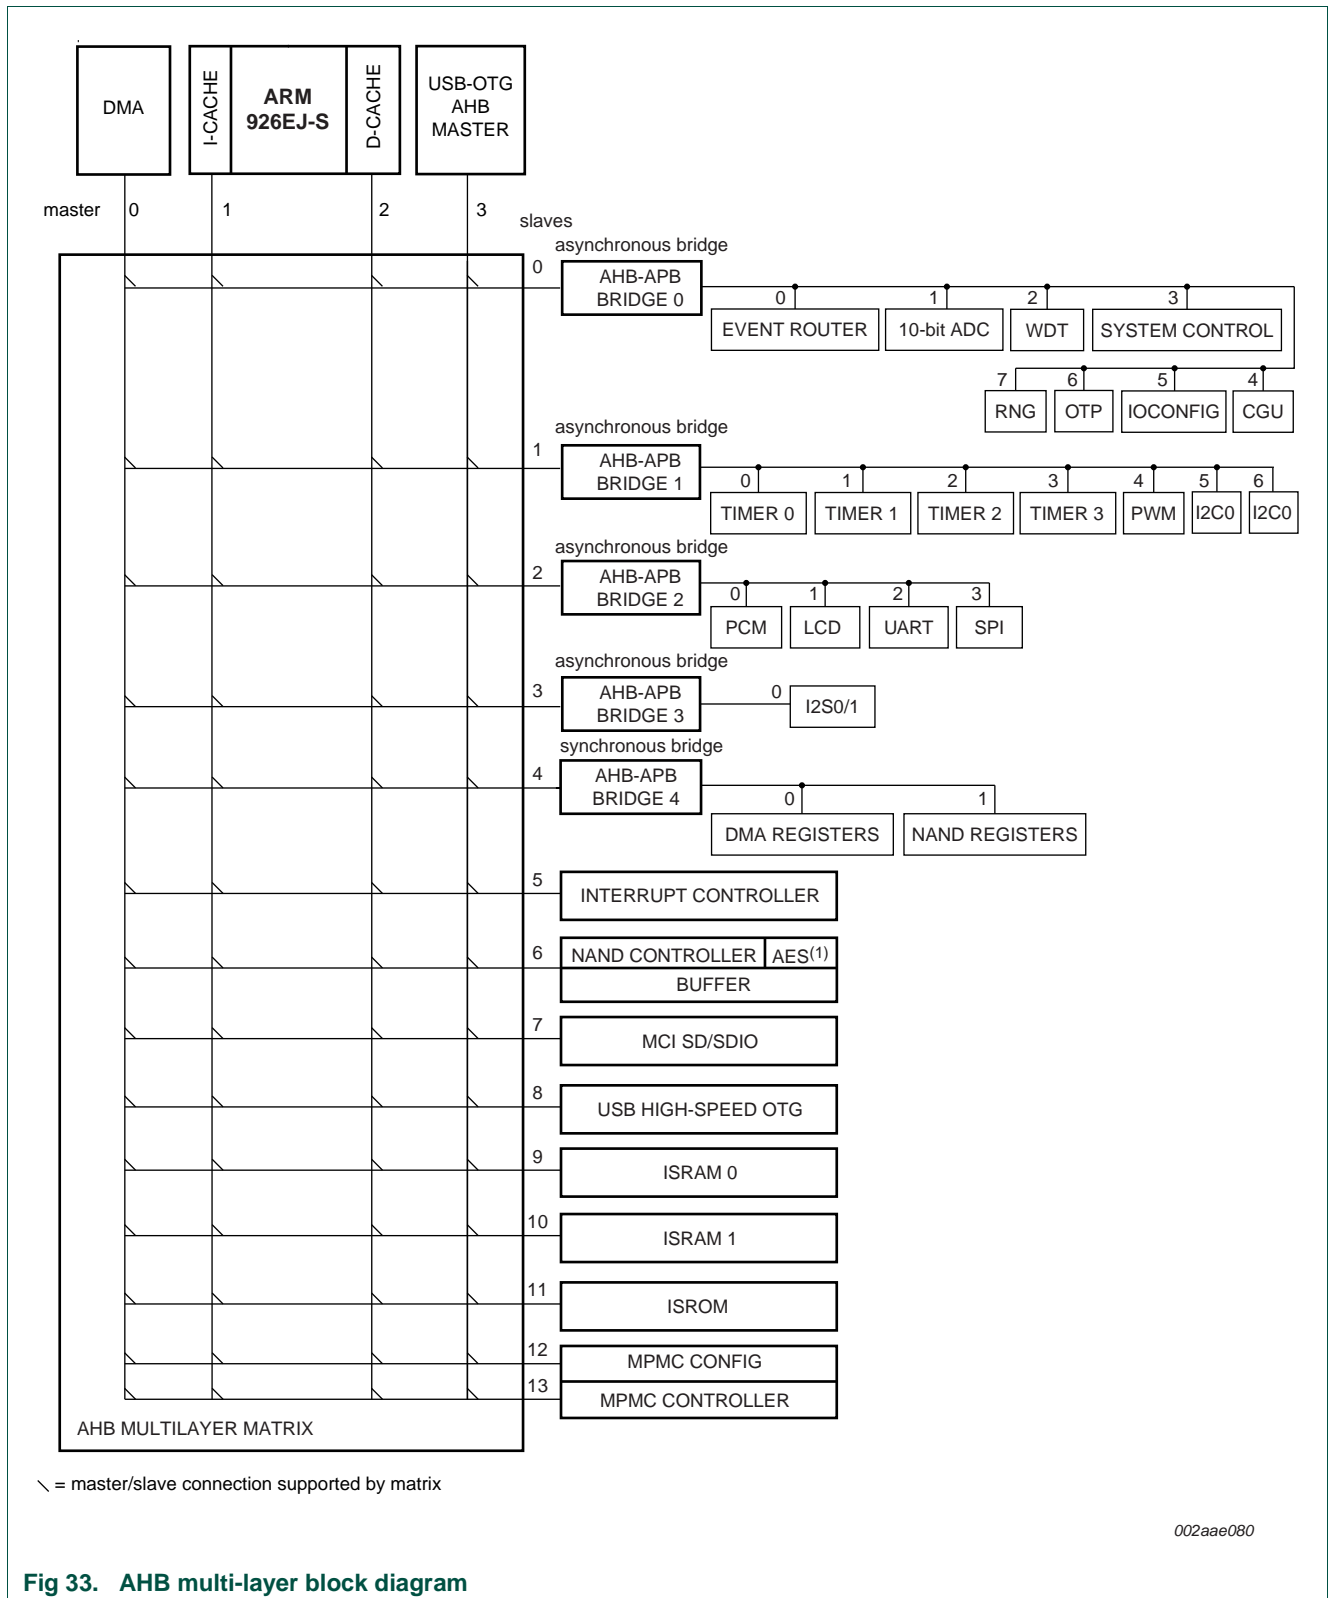

AHB (Advanced High-performance Bus) is a generation of AMBA bus, which is intended to address the requirements of high-performance designs. AMBA AHB is a level of bus, which sits above the APB and implements the features required for high-performance, high clock frequency systems, including:

- Burst transfers between bus masters and slaves on one layer
- Single cycle bus master hand over
- Single clock edge operation
- Non-tri state implementation.

In a multilayer AHB each layer has only one master. The benefits of a multilayer AHB are:

- This allows an increased bandwidth in comparison to one layer with more than one master.
- The master to slave mixing can be done without arbitration.
- The arbitration effectively becomes point arbitration at each peripheral and is only necessary when more than one master wants to access the same slave simultaneously.

2. General description

002aae080

## 2.1 Interface description

### 2.1.1 Clock Signals

Table 189. Clock signals of the AHB Module

Clock Name	I/O	Source/ Destination	Description
<b>Clock</b>			
AHB0_CLK	I	CGU	Main clock of the module. The logic in this module runs on this clock. Its frequency depends on the required speed for connected devices. The maximum frequency of AHB_CLK is 75 MHz.
<b>Enable signals (see <a href="#">Section 13–6.3.2</a>)</b>			
AHB_M<x>_DISABLE_REQ	I	CGU	Master bus access deny request. When this signal becomes high the master may complete its current AHB transfer. After this transfer no new bus access is allowed.
AHB_M<x>_DISABLE_GRANT	I	CGU	Master bus access denied. This signal indicates that the deny request is received and the last allowed bus transfer has finished. The master IP clock can be safely disabled by the CGU.

### 2.1.2 Reset Signals

The AHB is reset by the (active low) AHB reset through the CGU. Reset is de-asserted synchronously to AHB\_CLK; assertion may be done asynchronously to AHB\_CLK. NOTE: This signal must be asserted upon a power\_on reset.

### 2.1.3 System control register (Syscreg) signals

Table 190. External priority signals of the AHB Module (see [Table 27–563](#))

Name	Type	Description
AHB_M0_EXTPRIO	I	External priority signal for master zero. If this bit is set, this master has higher priority on the bus for slave x than the masters without its external priority signal set.
AHB_M1_EXTPRIO	I	External priority signal for master one. If this bit is set, this master has higher priority on the bus for slave x than the masters without its external priority signal set.
AHB_M2_EXTPRIO	I	External priority signal for master two. If this bit is set, this master has higher priority on the bus for slave x than the masters without its external priority signal set.
AHB_M3_EXTPRIO	I	External priority signal for master three. If this bit is set, this master has higher priority on the bus for slave x than the masters without its external priority signal set.

**Table 191. Shadow signals of the AHB Module (see [Table 27–564](#))**

Name	Type	Description
AHB_M1_SHADOW_POINTER	I	This signal is provided to be able to change the memory mapping for ARM instruction bus. The actual re-mapping pointer is a 32-bitvector of which the lower10 bits are '0'. It is freely programmable in increments of 1 kByte.
AHB_M2_SHADOW_POINTER	I	This signal is provided to be able to change the memory mapping for ARM data bus. The actual re-mapping pointer is a 32-bitvector of which the lower10 bits are '0'. It is freely programmable in increments of 1 kByte.

### 3. Register overview

Not applicable. The AHB has no internal registers.

### 4. Register description

This multi-layer AHB is based on the AHB-Lite protocol. This means that the layers do not support request and grant. Also retry and split transactions are not supported. The bus selects the master to the wanted slave. This selection is done without waitstates. The address decoding of a master to a slave port and routing of the address and command signals to the slave is done within one cycle.

Each master has a full address decoder for all slave peripherals in the system. A key issue in a multi-layer AHB system is the overall system complexity, arising from the number of concurrent actions possible in the system. To reduce the system complexity, the AHB multi-layer system only supports a unified memory map. This means all masters and slaves share a single, global 32-bit address space, and any master can select any slave in the system.

To avoid breaking the unified memory space, a specific section of the unified memory map is assigned as a shadow memory section. This memory section is virtual, i.e. no actual memory is present at the shadow address. It can be seen as a copy of a section of unified memory, specific to each master.

The bus arbiter is integrated in the AHB Multilayer and provides bus arbitration for a total of 4 bus masters. The scheduler determines the priority of the master by making use of the external priority.

The following list summarizes the rules which determine which master for the slave x is granted the bus:

1. A master requesting the bus is given the priority over a master not requesting the bus
2. If only one master with the highest externally assigned priority is requesting the bus, it will receive the bus regardless of the underlying scheduling algorithm
3. If no external priority is specified or all masters are of the same external priority, then the master selected by the scheduler is given the bus
4. If no master is requesting the bus layer then the layer will generate idle cycles
5. A master that locks the bus can keep it indefinitely.

The user set the external priority bits in the configuration register block. The re-arbitration is done in one cycle (at the same time as the next access to a slave port), i.e there are no waitstates.

This chip supports 4 masters and 14 slaves. An overview is given in following table:

**Table 192. Shadow signals of the AHB Module**

Masters	Description	Slaves	Description
Master 0	Simple DMA	Slave port 0	APB0
Master 1	ARM926 Instruction	Slave port 1	APB1
Master 2	ARM926 Data	Slave port 2	APB2
Master 3	USB OTG	Slave port 3	APB3
		Slave port 4	APB4
		Slave port 5	Interrupt controller
		Slave port 6	Internal RAM0
		Slave port 7	Nand flash controller
		Slave port 8	Mobile storage SD/MMC
		Slave port 9	USB OTG slave
		Slave port 10	Internal sram0
		Slave port 11	Internal sram1
		Slave port 12	MPMC configuration
		Slave port 13	MPMC

## 5. Power optimization

When a master wishes to enter a power down mode, its IP clock can be stopped using the CGU. For this, the CGU can apply a 'disable request'. The corresponding master will finish its current bus transfer, else this will cause the corresponding slave device to be locked. As soon as the transfers is completed the 'disable grant' signal becomes high and the CGU can safely remove the IP clock of the master.

Slave devices connected to the AHB can use the clock-enable feature to selectively gate the clock as long as required.

### 1. How to read this chapter

The AES block of the NAND flash controller and its clock and reset signals are available on LPC3154 only. See [Table 13–193](#) for related clocks and registers in the CGU.

**Table 193. AES specific clocks and registers**

	Description	LPC3152	LPC3154
NANDFLASH_AES_CLK	NAND flash AES clock	no	yes
PCR12	Power Control Register for NANDFLASH_AES_CLK	no	yes
PSR12	Power Status Register for NANDFLASH_AES_CLK	no	yes
ESR12	Enable Select and enable Register for NANDFLASH_AES_CLK	no	yes
NANDFLASH_CTRL_AES_RESET_N_SOFT	Reset register for AES clock domain of Nandflash Controller	no	yes

### 2. Introduction

The Clock Generation Unit (CGU) is used for delivering all the clocks which are needed for the blocks of the digital die.

#### 2.1 Features

This module has the following features:

- Several advanced features to optimize the system for low power:
  - All output clocks can be disabled individually for flexible power optimization. Some modules have automatic clock gating, which means that they are only active when (bus) access to the module is required.
  - Variable clock scaling for automatic power optimization of the AHB bus (high clock frequency when the bus is active, low clock frequency when the bus is idle).
  - Clock wake-up feature: when switched off, module clocks can be programmed to be activated automatically on the basis of an (external) event detected by the Event Router. An example of the use of this feature would be that all clocks (including the ARM / bus clocks) are off and activated automatically when a button is pressed.
- Seven Clock sources:
  - Reference clock is generated by the oscillator with an external 12 MHz crystal.
  - Two external clock signals from the I2SRX\_BCK0 and I2SRX\_WS0 pins (used for generating audio frequencies in I2SRX0 / I2STX0 slave mode).
  - Two external clock signals from the I2SRX\_BCK1 and I2SRX\_WS1 pins (used for generating audio frequencies in I2SRX1 / I2STX1 slave mode).
  - Programmable system clock frequency is generated by the System PLL.

- Programmable audio clock frequency (typically  $512 \times f_s$ ) is generated by the Audio PLL.

Both the System PLL and the Audio PLL generate their own frequencies based on their (individual) reference clocks. The reference clocks can be programmed to the oscillator clock, or one of the external clock signals.

- Highly flexible switchbox to distribute the signals from the clock sources to the module clocks:
  - Each clock generated by the CGU is derived from one of the base clocks and optionally divided by a fractional divider.
  - Each base clock can be programmed to have any one of the clock sources as an input clock.
  - Fractional dividers can be used to divide a base clock by a fractional number.
  - Fractional dividers support clock stretching to obtain a (near) 50% duty cycle output clock.
- Register interface to reset all modules under software control.
- Based on the input of the Watchdog timer, the CGU can generate a system-wide reset in the case of a system hang-up.

### 3. General description

---

The CGU generates all the clock signals in the system and controls the reset signals for all modules. As shown in the block diagram of the CGU in [Figure 13–34](#), the CGU has a regular structure. Each output clock generated by the CGU belongs to one of the system or audio clock domains. Each clock domain is fed by a single base clock that originates from one of the available clock sources.

Within a clock domain, fractional dividers are available to divide the base clock into a lower frequency. Within most clock domains, the output clocks are again grouped into one or more sub domains.

All output clocks within one sub domain are either all generated by the same fractional divider or they are connected directly to the base clock. Therefore all output clocks within one sub domain have the same frequency and all output clocks within one clock domain are synchronous because they originate from the same base clock. The CGU has a reference clock (generated by the oscillator) and several external clock inputs.

The CGU also has several phase locked loop (PLL) circuits to generate clock signals that can be used for system clocks and/or audio clocks. All clock sources, except the output of the PLLs, can be used as reference input for the PLLs.

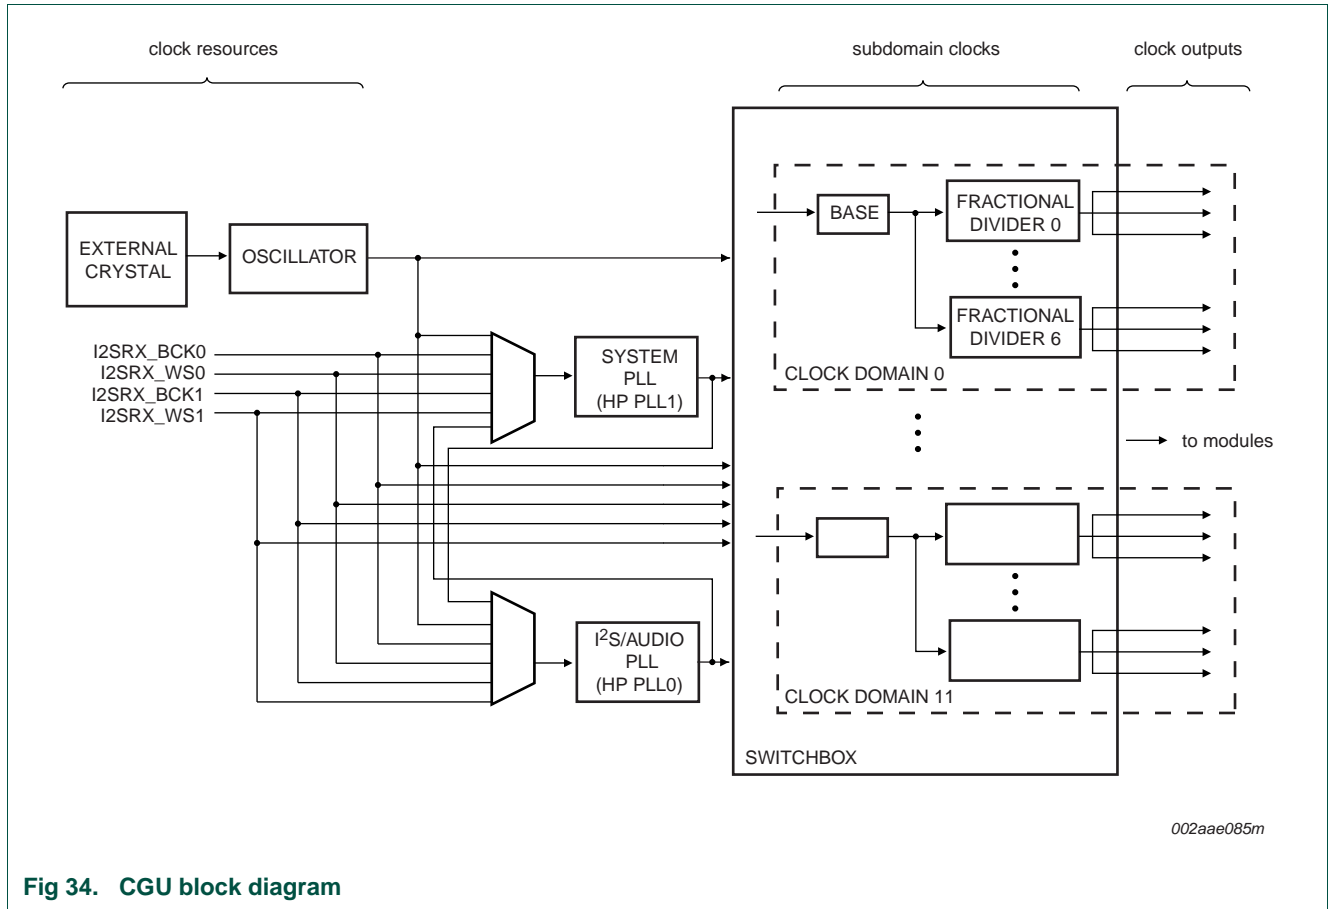

Fig 34. CGU block diagram

Table 194. CGU base clock domains and associated fractional dividers

Base clock domain	Domain #	Fractional dividers
SYS_BASE	0	0 to 6
AHB_APB0_BASE	1	7 and 8
AHB_APB1_BASE	2	9 and 10
AHB_APB2_BASE	3	11 to 13
AHB_APB3_BASE	4	14
PCM_BASE	5	15
UART_BASE	6	16
CLK1024FS_BASE	7	17 to 22
I2SRX_BCK0_BASE	8	none
I2SRX_BCK1_BASE	9	none
SPI_CLK_BASE	10	23
SYSCLK_O_BASE	11	none

### 3.1 Interface description

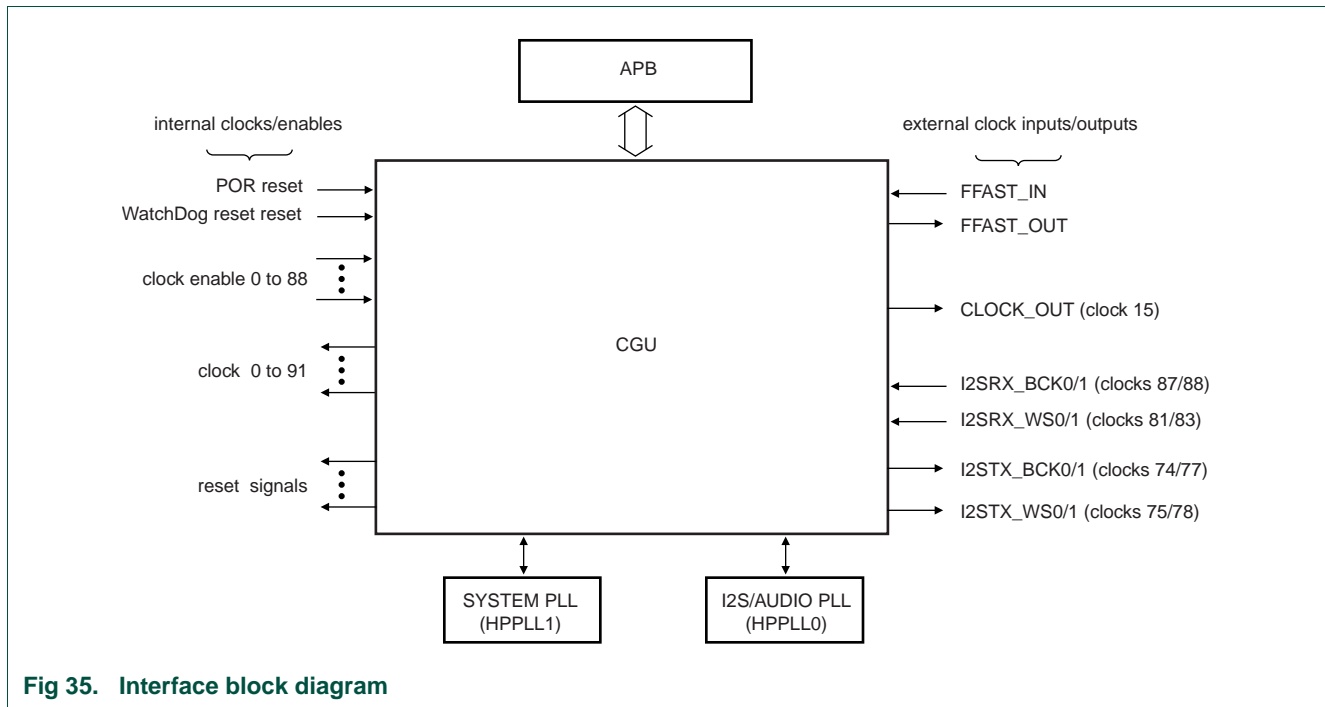

Fig 35. Interface block diagram

#### 3.1.1 Clock signals

In the following table all base clocks and their derived clocks are listed. Each clock is assigned a number which is used in the corresponding Power Control Registers (PCR0 to PCR91) and the Power Status Registers (PSR0 to PSR91), see [Table 13–196](#).

The LPC315x has a total of 24 fractional dividers FDC0 to FDC23 which are distributed among the 12 base clock domains. Each base clock domain has pre-assigned fractional dividers which can be used to further divide the base clock (see [Table 13–194](#)). The output of the fractional dividers or base clock can be used as source for the clocks belonging to that domain.

In addition the SYS\_BASE clock domain has seven dynamic fractional dividers (DYN\_FDC0 to DYN\_FDC6) to generate slow clocks corresponding to FDC0 to FDC6. When dynamic fractional dividers are enabled, LPC315x automatically switches to slow clocks (DYNC\_FDC0 - DYNC\_FDC6) from fast clocks (FDC0 - FDC6) when there is no AHB bus activity. For more details, see [Section 13–6.1.5](#).

For a detailed description of the CGU switchbox see [Section 13–6.1](#).

Table 195. Clock signals of the CGU<sup>[1]</sup>

Base clock domain (selection stage)	Clock source/spreading stage	Clock Name	Clock #	Description
SYS_BASE	FDC0_CLK to FDC6_CLK or SYS_BASE_CLK	APB0_CLK	0	Clock for AHB side of AHB_TO_APB0 bridge.
		APB1_CLK	1	Clock for AHB side of AHB_TO_APB1 bridge.
		APB2_CLK	2	Clock for AHB side of AHB_TO_APB2 bridge.
		APB3_CLK	3	Clock for AHB side of AHB_TO_APB3 bridge.
		APB4_CLK	4	Clock for AHB side of AHB_TO_APB4 bridge. Note that AHB_TO_APB4 is a synchronous bridge. So no separate clock is needed for the APB side of the bridge.
		AHB_TO_INTC_CLK	5	Clock for INTC bridge. This bridge is needed for DTL interface of the Interrupt Controller.
		AHB0_CLK	6	Clock for AHB Multi-layer.
		EBI_CLK	7	Clock for EBI
		DMA_PCLK	8	Clock for APB interface of DMA
		DMA_CLK_GATED	9	Clock for AHB interface of DMA
		NANDFLASH_S0_CLK	10	AHB port clock of the module
		NANDFLASH_ECC_CLK	11	Main clock for ECC part in the module
		NANDFLASH_AES_CLK	12	Main clock for the AES block. This clock should run on half the NANDFLASH_NAND_CLK frequency.
		NANDFLASH_NAND_CLK	13	Main clock for the module
		NANDFLASH_PCLK	14	APB port clock of the module
		CLOCK_OUT	15	Free to use clock, with restriction that this clock is derived from SYS_base. This is the clock for the CLK_OUT pin.
		ARM926_CORE_CLK	16	Core clock of ARM926
ARM926_BUSIF_CLK	17	AHB clock for ARM.		

Table 195. Clock signals of the CGU<sup>[1]</sup> ...continued

Base clock domain (selection stage)	Clock source/spreading stage	Clock Name	Clock #	Description
SYS_BASE	FDC0_CLK to FDC6_CLK or SYS_BASE_CLK	ARM926_RETIME_CLK	18	The retime clock of the ARM is used for signifying the rising edge of the AHB clock for the instruction and data of the AHB by making use of IHCLKEN and DHCLKEN. The frequency of the retime clock must be equal to its base clock.
		SD_MMC_HCLK	19	AHB interface clock of the MCI
		SD_MMC_CCLK_IN	20	The card interface input clock of MCI
		USB_OTG_AHB_CLK	21	AHB clk of USB_OTG
		ISRAM0_CLK	22	AHB clock for internal SRAM0 controller
		RED_CTL_RSCLK	23	Clock used for Redundancy Controller of Internal memories
		ISRAM1_CLK	24	AHB clock for internal SRAM1 controller
		ISROM_CLK	25	AHB clock for internal SROM controller
		MPMC_CFG_CLK	26	AHB clock for MPMC
		MPMC_CFG_CLK2	27	Clock for timing all external memory transfers. Should be synchronous to HCLK, where this MPMC_CFG_CLK2 (MPMCCLK) can be twice the frequency of HCLK
		MPMC_CFG_CLK3	28	Clock used for External Refresh Generator. This clock has to run at the SYS_base frequency
		INTC_CLK	29	Clock for Interrupt Controller Clock at the DTL interface
		AHB_APB0_BASE	FDC7_CLK to FDC8_CLK or AHB_APB0_BASE	AHB_TO_APB0_PCLK
EVENT_ROUTER_PCLK	31			APB clock for Event Router
ADC_PCLK	32			APB clock for 10-bit ADC
ADC_CLK	33			10-bit ADC clock
WDOG_PCLK	34			APB clock for WDOG
IOCONF_PCLK	35			APB clock for IOCONFIG
CGU_PCLK	36			APB clock for CGU
SYSCREG_PCLK	37			APB clock for SYSREG
OTP_PCLK	38			APB clock for One-Time Programmable (OTP) memory
RNG_PCLK	39			Clock for Random number generator

Table 195. Clock signals of the CGU<sup>[1]</sup> ...continued

Base clock domain (selection stage)	Clock source/spreading stage	Clock Name	Clock #	Description
AHB_APB1_BASE	FDC9_CLK to FDC10_CLK or AHB_APB1_BASE	AHB_TO_APB1_PCLK	40	Asynchronous Clock for APB interface of AHB_TO_APB1 bridge
		TIMER0_PCLK	41	APB clock for Timer0
		TIMER1_PCLK	42	APB clock for Timer1
		TIMER2_PCLK	43	APB clock for Timer2
		TIMER3_PCLK	44	APB clock for Timer3
		PWM_PCLK	45	APB clock for PWM
		PWM_PCLK_REGS	46	Gated APB clock, used for register access of PWM
		PWM_CLK	47	Clock used for generating the output of the PWM
		I <sup>2</sup> C0_PCLK	48	APB clock for I <sup>2</sup> C0
		I <sup>2</sup> C1_PCLK	49	APB clock for I <sup>2</sup> C1
AHB_APB2_BASE	FDC11_CLK to FDC13_CLK or AHB_APB2_BASE	AHB_TO_APB2_PCLK	50	Clock for APB interface of AHB_TO_APB2 bridge.
		PCM_PCLK	51	APB clock for PCM. Used to synchronize the DMA handshake signals; needs to run continuously.
		PCM_APB_PCLK	52	APB Interface clock for PCM. Used to perform register accesses.
		UART_APB_CLK	53	APB clock for UART
		LCD_PCLK	54	APB clock for LCD
		LCD_CLK	55	Clock used by data and control flow towards the external LCD Controller.
		SPI_PCLK	56	APB bus clock of SPI.
		SPI_PCLK_GATED	57	Gated version of APB bus clock of SPI

Table 195. Clock signals of the CGU<sup>[1]</sup> ...continued

Base clock domain (selection stage)	Clock source/spreading stage	Clock Name	Clock #	Description
AHB_APB3_BASE	FDC14_CLK or AHB_APB3_BASE	AHB_TO_APB3_PCLK	58	Asynchronous Clock for APB interface of AHB_TO_APB3 bridge
		I2S_CFG_PCLK	59	APB clock for I2S configuration block
		EDGE_DET_PCLK	60	APB clock for EDGE_DET
		I2STX_FIFO_0_PCLK	61	APB clock for I2STX_FIFO_0 (I2STX_0)
		I2STX_IF_0_PCLK	62	APB clock for I2STX_IF_0 (I2STX_0)
		I2STX_FIFO_1_PCLK	63	APB clock for I2STX_FIFO_1 (I2STX_1)
		I2STX_IF_1_PCLK	64	APB clock for I2STX_IF_1 (I2STX_1)
		I2SRX_FIFO_0_PCLK	65	APB clock for I2SRX_FIFO_0 (I2SRX_0)
		I2SRX_IF_0_PCLK	66	APB clock for I2SRX_IF_0 (I2SRX_0)
		I2SRX_FIFO_1_PCLK	67	APB clock for I2SRX_FIFO_1 (I2SRX1)
		I2SRX_IF_1_PCLK	68	APB clock for I2SRX_IF_1 (I2SRX1)
		-	69	reserved
		-	70	reserved
		PCM_BASE	FDC15_CLK or PCM_BASE	PCM_CLK_IP
UART_BASE	FDC16_CLK or UART_BASE	UART_U_CLK	72	Used for UART baud-rate generation
CLK1024FS_BASE	FDC17_CLK to FDC22_CLK or CLK1024FS_BASE	I2S_EDGE_DETECT_CLK	73	Sampling frequency clock. Used to generate NEWSAM flag from edge_detection.
		I2STX_BCK0_N	74	I2S Bit Clock of I2STX_0 (I2STX_0)
		I2STX_WS0	75	I2S Word Select of I2STX_0 (I2STX_0)
		I2STX_CLK0	76	System clock for external reference of I2STX_IF_0 (I2STX_0)
		I2STX_BCK1_N	77	I2S Bit Clock of I2STX_1 (I2STX_1)
		I2STX_WS1	78	I2S Word Select of I2STX_1 (I2STX_1)
		CLK_256FS	79	256 fs system clock for external reference. Also used as system clock for external reference of I2STX_1.
		I2SRX_BCK0_N	80	I2S Bit Clock of I2SRX_IF_0 in master mode (I2SRX_0)
		I2SRX_WS0	81	I2S Word Select of I2SRX_IF_0 (I2SRX_0)
		I2SRX_BCK1_N	82	I2S Bit Clock of I2SRX_IF_1 in master mode (I2SRX_1)
		I2SRX_WS1	83	I2S Word Select of I2SRX_IF_1 (I2SRX_1)
		-	84 to 86	reserved

Table 195. Clock signals of the CGU<sup>[1]</sup> ...continued

Base clock domain (selection stage)	Clock source/spreading stage	Clock Name	Clock #	Description
I2SRX_BCK0_BASE	I2SRX_BCK0_BASE	I2SRX_BCK0	87	I2S Bit clock of I2SRX_0. This clock is used in both master and slave modes.
I2SRX_BCK1_BASE	I2SRX_BCK1_BASE	I2SRX_BCK1	88	I2S Bit clock of I2SRX_1. This clock is used in both master and slave modes.
SPI_CLK_BASE	FDC16_CLK or SPI_CLK_BASE	SPI_CLK	89	Main clock of the SPI module.
		SPI_CLK_GATED	90	Gated version of main clock of the SPI module.
SYSClk_O_BASE	SYSClk_O_BASE	SYSClk_O	91	Clock for SYSClk_O pin.

[1] See [Table 13–193](#) for clocks that are part specific and not implemented on all LPC315x parts.

### 3.1.2 Interrupt request signals of CGU

The CGU does not generate interrupts.

### 3.1.3 DMA transfer signals of CGU

The CGU has no DMA transfer signals.

### 3.1.4 Reset signals of the CGU

CGU generates system wide reset based on POR and WatchDog reset events. Apart from generating a system wide reset, the CGU also provides a register interface to generate individual reset to the peripherals, memories, and bridges present on the chip (see [Table 13–197](#)).

**Remark:** The AHB\_TO\_APB0 resets are reserved. It is not allowed to use this reset, as it cannot be disabled again afterwards.

## 4. Register overview

The CGU consists of two register parts: the clock switchbox registers and the configuration registers. Both register parts use different base addresses.

### 4.1 Register overview of clock switchbox

Table 196. Register overview: CGU clock switchbox (register base address 0x1300 4000)<sup>[1]</sup>

Name	R/W	Address Offset	Description
<b>Switch configuration registers for base clocks</b>			
SCR0	R/W	0x000	Switch Configuration Register for SYS base
SCR1	R/W	0x004	Switch Configuration Register for AHB0_APB0 base
SCR2	R/W	0x008	Switch Configuration Register for AHB0_APB1 base
SCR3	R/W	0x00C	Switch Configuration Register for AHB0_APB2 base
SCR4	R/W	0x010	Switch Configuration Register for AHB0_APB3 base
SCR5	R/W	0x014	Switch Configuration Register for PCM base
SCR6	R/W	0x018	Switch Configuration Register for UART base

[1] See [Table 13–193](#) for registers that are part specific and not implemented on all LPC315x parts.

## 4.2 Register overview of the CGU configuration registers

Table 197. Register overview: CGU configuration block (register base address 0x1300 4C00)<sup>[1]</sup>

Name	R/W	Address Offset	Description
<b>Power and oscillator control</b>			
POWERMODE	R/W	0x000	Power mode register; Power up reset initiated by an external signal 'POR'
WD_BARK	R	0X004	Watch dog bark register; Power up reset is initiated by an internal signal from the watchdog.
FFAST_ON	R/W	0X008	Activate fast oscillator register
FFAST_BYPASS	R/W	0x00C	Bypass comparator register fast oscillator
<b>Reset control</b>			
APB0_RESETN_SOFT	R/W	0x010	Reset register for AHB part of AHB_TO_APB0 bridge; reserved. <sup>[2]</sup>
AHB_TO_APB0_PNRES_SOFT	R/W	0x014	Reset register for APB part of AHB_TO_APB0 bridge and for OTP; reserved. <sup>[2]</sup>
APB1_RESETN_SOFT	R/W	0x018	Reset register for AHB part of AHB_TO_APB1 bridge
AHB_TO_APB1_PNRES_SOFT	R/W	0x01C	Reset register for APB part of AHB_TO_APB1 bridge
APB2_RESETN_SOFT	R/W	0x020	Reset register for AHB part of AHB_TO_APB2 bridge
AHB_TO_APB2_PNRES_SOFT	R/W	0X024	Reset register for APB part of AHB_TO_APB2 bridge
APB3_RESETN_SOFT	R/W	0X028	Reset register for AHB part of AHB_TO_APB3 bridge
AHB_TO_APB3_PNRES_SOFT	R/W	0x02C	Reset register for APB part of AHB_TO_APB3 bridge
APB4_RESETN_SOFT	R/W	0x030	Reset register for AHB_TO_APB4 bridge; Only one reset is needed, because this bridge is synchronous.
AHB_TO_INTC_RESETN_SOFT	R/W	0x034	Reset register for AHB_TO_INTC
AHB0_RESETN_SOFT	R/W	0x038	Reset register for AHB0; reserved. <sup>[2]</sup>
EBI_RESET_N_SOFT	R/W	0x03C	Reset register for EBI
PCM_PNRES_SOFT	R/W	0x040	Reset register for APB domain of PCM; Asynchronous APB domain reset for PCM.
PCM_RESET_N_SOFT	R/W	0X044	Reset register for synchronous clk_ip domain of PCM
PCM_RESET_ASYNC_N_SOFT	R/W	0X048	Reset register for asynchronous clk_ip domain of PCM
TIMER0_PNRES_SOFT	R/W	0x04C	Reset register for Timer0
TIMER1_PNRES_SOFT	R/W	0x050	Reset register for Timer1
TIMER2_PNRES_SOFT	R/W	0x054	Reset register for Timer2
TIMER3_PNRES_SOFT	R/W	0x058	Reset register for Timer3

**Table 197. Register overview: CGU configuration block (register base address 0x1300 4C00)<sup>[1]</sup> ...continued**

Name	R/W	Address Offset	Description
ADC_PRESETN_SOFT	R/W	0x05C	Reset register for controller of 10 bit ADC Interface
ADC_RESETN_ADC10BITS_SOFT	R/W	0x060	Reset register for A/D converter of ADC Interface; global reset
PWM_RESET_AN_SOFT	R/W	0X064	Reset register for PWM; asynchronous.
UART_SYS_RST_AN_SOFT	R/W	0X068	Reset register UART/IrDA; asynchronous.
I2C0_PNRES_SOFT	R/W	0x06C	Reset register for I2C0
I2C1_PNRES_SOFT	R/W	0x070	Reset register for I2C1
I2S_CFG_RST_N_SOFT	R/W	0x074	Reset register for I2S_Config; I2S_config APB domain reset
I2S_NSOF_RST_N_SOFT	R/W	0x078	Reset register for NSOF counter of I2S_CONFIG
EDGE_DET_RST_N_SOFT	R/W	0x07C	Reset register for Edge_det
I2STX_FIFO_0_RST_N_SOFT	R/W	0x080	Reset register for I2STX_FIFO_0
I2STX_IF_0_RST_N_SOFT	R/W	0X084	Reset register for I2STX_IF_0
I2STX_FIFO_1_RST_N_SOFT	R/W	0X088	Reset register for I2STX_FIFO_1
I2STX_IF_1_RST_N_SOFT	R/W	0x08C	Reset register for I2STX_IF_1
I2SRX_FIFO_0_RST_N_SOFT	R/W	0x090	Reset register for I2SRX_FIFO_0
I2SRX_IF_0_RST_N_SOFT	R/W	0x094	Reset register for I2SRX_IF_0
I2SRX_FIFO_1_RST_N_SOFT	R/W	0x098	Reset register for I2SRX_FIFO_1
I2SRX_IF_1_RST_N_SOFT	R/W	0x09C	Reset register for I2SRX_IF_1
reserved	R/W	0X0A0 to 0x0B0	-
LCD_PNRES_SOFT	R/W	0x0B4	Reset register for LCD Interface
SPI_PNRES_APB_SOFT	R/W	0x0B8	Reset register for apb_clk domain of SPI
SPI_PNRES_IP_SOFT	R/W	0x0BC	Reset register for ip_clk domain of SPI
DMA_PNRES_SOFT	R/W	0x0C0	Reset register for DMA
NANDFLASH_CTRL_ECC_RESET_N_SOFT	R/W	0X0C4	Reset register for ECC clock domain of Nandflash Controller
NANDFLASH_CTRL_AES_RESET_N_SOFT	R/W	0X0C8	Reset register for AES clock domain of Nandflash Controller
NANDFLASH_CTRL_NAND_RESET_N_SOFT	R/W	0x0CC	Reset register for of Nandflash Controller; Reset signal for the nand_clk domain of NAND flash controller
SD_MMC_PNRES_SOFT	R/W	0x0D4	Reset register for MCI synchronous with AHB clock; The AND function of this reset signal and sd_mmc_nres_cclk_in will result in the reset signal for MCI.
SD_MMC_NRES_CCLK_IN_SOFT	R/W	0x0D8	Reset register for MCI synchronous with IP clock; The AND function of this reset signal and sd_mmc_nres will result in the reset signal for MCI.
USB_OTG_AHB_RST_N_SOFT	R/W	0x0DC	Reset register for USB_OTG

**Table 197. Register overview: CGU configuration block (register base address 0x1300 4C00)<sup>[1]</sup> ...continued**

Name	R/W	Address Offset	Description
RED_CTL_RESET_N_SOFT	R/W	0x0E0	Reset register for Redundancy Controller
AHB_MPMC_HRESTN_SOFT	R/W	0x0E4	Reset register for MPMC
AHB_MPMC_REFRESH_RESETN_SOFT	R/W	0x0E8	Reset register for refresh generator used for MPMC
INTC_RESETRN_SOFT	R/W	0x0EC	Reset register for Interrupt Controller.
<b>PLL control (audio PLL)</b>			
HP0_FIN_SELECT	R/W	0x0F0	Register for selecting input to high HPPLL0
HP0_MDEC	R/W	0x0F4	M-divider register of HP0 PLL
HP0_NDEC	R/W	0x0F8	N-divider register of HP0 PLL
HP0_PDEC	R/W	0x0FC	P-divider register of HP0 PLL
HP0_MODE	R/W	0x100	Mode register of HP0 PLL
HP0_STATUS	R	0x104	Status register of HP0 PLL
HP0_ACK	R	0x108	Ratio change acknowledge register of HP0 PLL
HP0_REQ	R/W	0x10C	Ratio change request register of HP0 PLL
HP0_INSELR	R/W	0x110	Bandwidth selection register of HP0 PLL
HP0_INSELI	R/W	0x114	Bandwidth selection register of HP0 PLL
HP0_INSELP	R/W	0x118	Bandwidth selection register of HP0 PLL
HP0_SELR	R/W	0x11C	Bandwidth selection register of HP0 PLL
HP0_SELI	R/W	0x120	Bandwidth selection register of HP0 PLL
HP0_SELP	R/W	0x124	Bandwidth selection register of HP0 PLL
<b>PLL control (system PLL)</b>			
HP1_FIN_SELECT	R/W	0x128	Register for selecting input to high HP1 PLL
HP1_MDEC	R/W	0x12C	M-divider register of HP1 PLL
HP1_NDEC	R/W	0x130	N-divider register of HP1 PLL
HP1_PDEC	R/W	0x134	P-divider register of HP1 PLL
HP1_MODE	R/W	0x138	Mode register of HP1 PLL
HP1_STATUS	R	0x13C	Status register of HP1 PLL
HP1_ACK	R	0x140	Ratio change acknowledge register of HP1 PLL
HP1_REQ	R/W	0x144	Ratio change request register of HP1 PLL
HP1_INSELR	R/W	0x148	Bandwidth selection register of HP1 PLL
HP1_INSELI	R/W	0x14C	Bandwidth selection register of HP1 PLL
HP1_INSELP	R/W	0x150	Bandwidth selection register of HP1 PLL
HP1_SELR	R/W	0x154	Bandwidth selection register of HP1 PLL
HP1_SELI	R/W	0x158	Bandwidth selection register of HP1 PLL
HP1_SELP	R/W	0x15C	Bandwidth selection register of HP1 PLL

[1] See [Table 13–193](#) for registers that are part specific and not implemented on all LPC315x parts.

- [2] The AHB\_TO\_APB0 resets are reserved. It is not allowed to use this reset, as it cannot be disabled again afterwards.

## 5. Register description

### 5.1 Clock switchbox registers

**Table 198. Switch configuration register SCR<base number> (SCR0 to SCR11, addresses 0x1300 4000 to 0x1300 402C)**

Bit	Symbol	R/W	Reset Value	Description
31:4		-	-	Reserved
3	STOP	R/W	0	Forces switch in disable mode (No frequency selected)
2	RESET	R/W	0	Asynchronous reset of both switches
1	ENF2	R/W	0	Enable side #2 of switch
0	ENF1	R/W	1	Enable side #1 of switch

**Table 199. Frequency select register 1 FS1\_<base number> (FS1\_0 to FS1\_11, addresses 0x1300 4030 to 0x1300 405C)**

Bit	Symbol	R/W	Reset Value	Description
31:3		-	-	Reserved
2:0	FS1	R/W	0x0	<p>The value of FS1 selects the input frequency for side #1 of the frequency switch. At reset, this side of the switch is enabled.</p> <p>The following input frequencies can be selected for FS1:</p> <p>0x0: ffast 12 MHz</p> <p>0x1: I2SRX_BCK0</p> <p>0x2: I2SRX_WS0</p> <p>0x3: I2SRX_BCK1</p> <p>0x4: I2SRX_WS1</p> <p>0x5: HPPLL0 (Audio/I2S PLL)</p> <p>0x6:HPPLL1 (System PLL)</p>

**Table 200. Frequency Select register 2 FS2\_<base number> (FS2\_0 to FS2\_11, addresses 0x1300 4060 to 0x1300 408C)**

Bit	Symbol	R/W	Reset Value	Description
31:3		-	-	Reserved
2:0	FS2	R/W	0x0	<p>The value of FS2 selects the input frequency for side #2 of the frequency switch. At reset, this side of the switch is disabled.</p> <p>The following input frequencies can be selected:</p> <p>0x0: ffast 12 MHz</p> <p>0x1: I2SRX_BCK0</p> <p>0x2: I2SRX_WS0</p> <p>0x3: I2SRX_BCK1</p> <p>0x4: I2SRX_WS1</p> <p>0x5: HPPLL0 (Audio/I2S PLL)</p> <p>0x6:HPPLL1 (System PLL)</p>

**Table 201. Switch Status register SSR<base number> (SSR0 to SSR11, addresses 0x1300 4090 to 0x1300 40BC)**

Bit	Symbol	R/W	Reset Value	Description
31:5	Reserved	-	-	Reserved
4:2	FS	R	0x0	Feedback of currently used frequency selection
1	FS2STAT	R	0x0	If true, side #2 of the frequency switch is currently enabled
0	F1STAT	R	0x1	If true, side #1 of the frequency switch is currently enabled

**Table 202. Power Control register PCR<clock number> (PCR0 to PCR91, addresses 0x1300 40C0 to 0x1300 422C)**

Bit	Symbol	R/W	Reset Value	Description
31:5		-	-	Reserved
4	ENOUT_EN	R/W	0	<p>When true, the clk enabling preview signal &lt;clk&gt;_enableout reflects the enable state for the second active edge of &lt;clk&gt;.</p> <p>Only the enableouts of the following clocks can be used in the CGU of the LPC315x:</p> <p>ARM926_BUSIF_CLK (7) MPMC_CFG_CLK (26)</p>
3	EXTEN_EN	R/W	0	<p>Enable external enabling (= enable generated from outside module). It allows a clock to be controlled by an input signal that the template names '&lt;clockname&gt;_enable'. An example are 'pclk' of APB busses used for configuration registers. These need only to be active when the register is accessed and can be controlled by the APB psel (only for 3 clock cycle accesses) signal through the external enable input.</p> <p><b>This bit can be set for these clocks:</b> PCM_APB_PCLK (52) EVENT_ROUTER_PCLK (31), ADC_PCLK (32), IOCONFIG_PCLK (35), CGU_PCLK (36), SYSCREG_PCLK (37), DMA_CLK_GATED (9), SPI_PCLK_GATED (57), SPI_CLK_GATED (90), PCM_CLK_IP (71), PWM_CLK_REGS (46) OTP_PCLK (38) (can only be used for OTP_PCLK by reading from OTP. The bit can not be used for writing and copying.)</p> <p><b>This bit should be kept zero (not used) for:</b> I2C0_PCLK (48) I2C1_PCLK (49) WDOG_PCLK (34) UART_APB_CLK (53) LCD_PCLK (54)</p>

**Table 202. Power Control register PCR<clock number> (PCR0 to PCR91, addresses 0x1300 40C0 to 0x1300 422C) ...continued**

Bit	Symbol	R/W	Reset Value	Description
2	WAKE_EN	R/W	1	When '0' wake up is overruled and the module clock remains active when wakeup is low. This control exists to support for power down modes. With the input signal 'wakeup' all the clocks that have WAKE_EN set can be centrally controlled. When wakeup becomes low, the clocks will be disabled and when wakeup is set high they will be enabled.
1	AUTO	R/W	1	When false Wakeup and External enable are overruled, only internal enabling via configuration and fractional divider remain active. This control is primary meant for debugging purposes, as when it is set to zero the clock is no longer affected by power saving modes.
0	RUN	R/W	1	When '0' clock is disabled. The following clocks are not powered down: ARM core clock, AHB bus clock, CGU clock, APB0 clock INTC clock, and the clocks from the IP that the code is running from(e.g. internal SRAM)

**Table 203. Power Status register PSR<clock number> (PSR0 to PSR91, addresses 0x1300 4230 to 0x1300 439C)**

Bit	Symbol	R/W	Reset Value	Description
31:2		-	-	Reserved
1	WAKEUP	R	1	Indicates the wakeup condition for this clock.
0	ACTIVE	R	1	Indicates clock is functional.

**Table 204. Enable Select register ESR0 to ESR29 (ESR0 to ESR29, addresses 0x1300 43A0 to 0x1300 4414)**

Bit	Symbol	R/W	Reset Value	Description
31:4		-	-	Reserved
3:1	ESR_SEL	R/W	0	Selection of fractional dividers 0 to 6 can be made for clocks of SYS base. 0 selects FDC0 1 selects FDC1 2 selects FDC2 3 selects FDC3 4 selects FDC4 5 selects FDC5 6 selects FDC6
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider indexed by ESR_SEL if 0 SYS_BASE_CLK is used.

**Table 205. Enable Select register ESR30 to ESR39 (ESR30 to ESR39, addresses 0x1300 4418 to 0x1300 443C)**

Bit	Symbol	R/W	Reset Value	Description
31:2		-	-	Reserved
1	ESR_SEL	R/W	0	Selection of fractional dividers 7 and 8 can be made for clocks of AHB0_APB0 base. 0 selects FDC7 1 selects FDC8
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider indexed by ESR_SEL if 0 AHB_APB0_BASE_CLK is used.

**Table 206. Enable Select register ESR40 to ESR49 (ESR40 to ESR49, addresses 0x1300 4440 to 0x1300 4464)**

Bit	Symbol	R/W	Reset Value	Description
31:2		-	-	Reserved
1	ESR_SEL	R/W	0	Selection of fractional dividers 9 and 10 can be made for clocks of AHB0_APB1 base. 0 selects FDC9 1 selects FDC10
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider indexed by ESR_SEL if 0 AHB_APB1_BASE_CLK is used.

**Table 207. Enable Select register ESR50 to ESR57 (ESR50 to ESR57, addresses 0x1300 4468 to 0x1300 4484)**

Bit	Symbol	R/W	Reset Value	Description
31:3		-	-	Reserved
2:1	ESR_SEL	R/W	0	Selection of fractional dividers 11 to 13 can be made for clocks of AHB0_APB2 base. 0 selects FDC11 1 selects FDC12 2 selects FDC13
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider indexed by ESR_SEL if 0 AHB_APB2_BASE_CLK is used.

**Table 208. Enable Select register ESR58 to ESR72 (ESR58 to ESR72, addresses 0x1300 4488 to 0x1300 44C0)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider. If 1, -FDC14 for ESR58 to ESR 70, -FDC15 for ESR71, -FDC16 for ESR72. If 0, -AHB_APB3_BASE_CLK is used for ESR58 to ESR70 -PCM_BASE_CLK is used for ESR71 -UART_BASE_CLK is used for ESR72

**Table 209. Enable Select register ESR73 to ESR86 (ESR73 to ESR86, addresses 0x1300 44C4 to 0x1300 44F8)**

Bit	Symbol	R/W	Reset Value	Description
31:4		-	-	Reserved
3:1	ESR_SEL	R/W	0	Selection of fractional dividers 17 to 22 can be made for clocks of the CLK1024FS base. 0 - selects FDC17 1 - selects FDC18 2 - selects FDC19 3 - selects FDC20 4 - selects FDC21 5 - selects FDC22
0	ESR_EN	R/W	0	When the ESR_EN is true an enable is generated from the fractional divider indexed by ESR_SEL if 0 CLK1024FS_BASE_CLK is used.

**Table 210. Enable Select register ESR87 to ESR88 (ESR87 to ESR88, addresses 0x1300 44FC to 0x1300 4500)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	ESR_EN	R/W	0	When the ESR_EN is 1, an enable is generated from the fractional 23. If 0 SPI_CLK_BASE_CLK is used.

**Table 211. Base control register 0 (BCR0, address 0x1300 4504)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FDRUN	R/W	0	When true, fractional dividers belonging to SYS base are allowed to function. This bit overrules the run bit in the control register of the fractional dividers. So when FDRUN is set low all fractional dividers will be disabled. The purpose is to be able to activate all fractional dividers of a certain base simultaneously, so that they run in sync.

**Table 212. Base Control register 1 (BCR1, address 0x1300 4508)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FDRUN	R/W	0	When true, fractional dividers belonging to AHB0_APB0 base are allowed to function. This bit overrules the run bit in the control register of the fractional dividers. So when FDRUN is set low all fractional dividers will be disabled. The purpose is to be able to activate all fractional dividers of a certain base simultaneously, so that they run in sync.

**Table 213. Base Control register 2 (BCR2, address 0x1300 450C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FDRUN	R/W	0	When true, fractional dividers belonging to AHB0_APB1 base are allowed to function. This bit overrules the run bit in the control register of the fractional dividers. So when FDRUN is set low all fractional dividers will be disabled. The purpose is to be able to activate all fractional dividers of a certain base simultaneously, so that they run in sync.

**Table 214. Base Control register 3 (BCR3, address 0x1300 4510)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FDRUN	R/W	0	When true, fractional dividers belonging to AHB0_APB2 base are allowed to function. This bit overrules the run bit in the control register of the fractional dividers. So when FDRUN is set low all fractional dividers will be disabled. The purpose is to be able to activate all fractional dividers of a certain base simultaneously, so that they run in sync.

**Table 215. Base Control register 7 (BCR7, address 0x1300 4514)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FDRUN	R/W	0	When true, fractional dividers belonging to CLK1024FS base are allowed to function. This bit overrides the run bit in the control register of the fractional dividers. So when FDRUN is set low all fractional dividers will be disabled. The purpose is to be able to activate all fractional dividers of a certain base simultaneously, so that they run in sync.

**Table 216. Fractional divider register 0 to 23 (except FDC17) (FDC0 to FDC23 (except FDC17), addresses 0x1300 4518 to 0x1300 4574)**

Bit	Symbol	R/W	Reset Value	Description
31:19		-	-	Reserved
18:11	MSUB	R/W	0xff	Modulo subtraction value. The MSUB value can be calculated according: $Fdiv = n/m * f$ $MSUB = -n$
10:3	MADD	R/W	0x1	Modulo addition value. The MADD value can be calculated according: $Fdiv = n/m * f$ $MADD = m-n$
2	FDCTRL_STRETCH	R/W	0x0	Enables the stretching option. When stretching the generated clocks will have approximate 50% duty cycle
1	FDCTRL_RESET	R/W	0x0	Asynchronous reset of the fractional divider
0	FDCTRL_RUN	R/W	0x0	Enables the fractional divider

**Table 217. Fractional Divider register 17 (FDC17, address 0x1300 455C)**

Bit	Symbol	R/W	Reset Value	Description
31:29		-	-	Reserved
28:16	MSUB	R/W	0xff	Modulo subtraction value. The MSUB value can be calculated according: $Fdiv = n/m * f$ $MSUB = -n$
15:3	MADD	R/W	0x1	Modulo addition value. The MADD value can be calculated according: $Fdiv = n/m * f$ $MADD = m-n$
2	FDCTRL_STRETCH	R/W	0x0	Enables the stretching option. When stretching the generated clocks will have approximate 50% duty cycle
1	FDCTRL_RESET	R/W	0x0	Asynchronous reset of the fractional divider
0	FDCTRL_RUN	R/W	0x0	Enables the fractional divider

**Table 218. Dynamic Fractional Divider register (DYN\_FDC0 to DYN\_FDC6, addresses 0x1300 4578 to 0x1300 4590)**

Bit	Symbol	R/W	Reset Value	Description
31:20		-	-	Reserved
19	STOP_AUTO_RESET	R/W	0	Disable auto reset of fractional divider when changing from high-to-low or from low-to-high divider values.
18:11	MSUB	R/W	0xff	The MSUB value can be calculated according: $F_{div} = n/m * f$ MSUB = -n
10:3	MADD	R/W	0x1	The MADD value can be calculated according: $F_{div} = n/m * f$ MADD = m-n
2	DYN_FDCTRL_STRETCH	R/W	0x0	Enables the stretching option, during low speed operations. Advised to use the same value as in the corresponding FDC stretch bit.
1	DYN_FDC_ALLOW	R/W	0x0	Setting this bit enables the dynamic fractional divider. Then: - FDC settings are the settings for high speed operations - DYN_FDC settings are the settings for slow speed operations
0	DYN_FDCTRL_RUN	R/W	0x0	Enables the fractional divider during low speeds.

**Table 219. Dynamic Fractional Divider Selection register (DYN\_SEL0 to DYN\_SEL6, addresses 0x1300 4594 to 0x1300 45AC)**

Bit	Symbol	R/W	Reset Value	Description
31:19		-	-	Reserved
8	mpmc_refresh_req	R/W	0	External SDRAM refresh generator transfers can enable high speed.  There is a special register setting in the 'external_refresh_generator' in which the duration (in SYS_BASE_CLK cycles) can be programmed of how long this 'mpmc_refresh_req' bit should be active at every refresh request. This allows every refresh cycle to trigger the high-speed operation. The purpose is to reduce SDRAM power consumption.
7	ecc_ram_busy	R/W	0	Hispeed mode during ECC activity of NANDflash Controller.  Note: Has always to be enabled during variable clock scaling.
6	usb_otg_mst_trans	R/W	0	USB OTG transfers can enable high speed
5	arm926_lp_d_ready	R/W	0	ARM926 data transfers can enable high-speed
4	arm926_lp_d_trans	R/W	0	ARM926 data transfers can enable high-speed

**Table 219. Dynamic Fractional Divider Selection register (DYN\_SEL0 to DYN\_SEL6, addresses 0x1300 4594 to 0x1300 45AC) ...continued**

Bit	Symbol	R/W	Reset Value	Description
3	arm926_lp_i_ready	R/W	0	ARM926 instruction last transfers can enable high-speed
2	arm926_lp_i_trans	R/W	0	ARM926 instruction transfers can enable high-speed
1	dma_ready	R/W	0	dma last transfers can enable high-speed
0	dma_trans	R/W	0	dma transfers can enable high-speed

## 5.2 Configuration registers

### 5.2.1 Power and oscillator control registers

See [Section 13–6.3](#) for a detailed description of the power mode.

**Table 220. Powermode register (POWERMODE, address 0x1300 4C00)**

Bit	Symbol	R/W	Reset Value	Description
31:2		-	-	Reserved
1:0	Powermode	R/W	0x1	00: Unsupported, results in unpredictable behaviour. 01: Normal operational mode. 10: Unsupported, results in unpredictable behaviour. 11: Wakeup enabled clocks are disabled until a wakeup event occurs.

**Table 221. Watchdog Bark register (WD\_BARK, address 0x1300 4C04)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	WD_BARK	R	0x1	Is set when a watchdog reset has occurred (read only). This bit is cleared only by a power on reset.

**Table 222. Fast Oscillator activate register (FFAST\_ON, 0x1300 4C08)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FFAST_ON	R/W	0x1	Activate fast oscillator

**Table 223. Fast Oscillator Bypass comparator register (FFAST\_BYPASS, 0x1300 4C0C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	FFAST_BYPASS	R/W	0x1	Oscillator test mode

### 5.2.2 Reset control registers

See [Section 13–6.3](#) for a detailed description of the reset configuration.

**Table 224. APB0\_RESETN\_SOFT register (address 0x1300 4C10)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	APB0_RESETN_SOFT	R/W	0x1	Reserved (It is not allowed to use this reset, as it cannot be disabled again afterwards).

**Table 225. AHB\_TO\_APB0\_PNRES\_SOFT register (address 0x1300 4C14)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	AHB_TO_APB0_PNRES_SOFT	R/W	0x1	Reserved (It is not allowed to use this reset, as it cannot be disabled again afterwards)

**Table 226. APB1\_RESETN\_SOFT register (address 0x1300 4C18)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	APB1_RESETN_SOFT	R/W	0x1	Reset for AHB part of AHB_TO_APB1 bridge

**Table 227. AHB\_TO\_APB1\_PNRES\_SOFT register (address 0x1300 4C1C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	AHB_TO_APB1_PNRES_SOFT	R/W	0x1	Reset for APB part of AHB_TO_APB1 bridge

**Table 228. APB2\_RESETN\_SOFT register (address 0x1300 4C20)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	APB2_RESETN_SOFT	R/W	0x1	Reset for AHB part of AHB_TO_APB2 bridge

**Table 229. AHB\_TO\_APB2\_PNRES\_SOFT register (address 0x1300 4C24)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	AHB_TO_APB2_PNRES_SOFT	R/W	0x1	Reset for APB part of AHB_TO_APB2 bridge

**Table 230. APB3\_RESETN\_SOFT register (address 0x1300 4C28)**

Bit	Symbol	Access	Reset Value	Description
31:1		-	-	Reserved
0	APB3_RESETN_SOFT	R/W	0x1	Reset for AHB part of AHB_TO_APB3 bridge

**Table 231. AHB\_TO\_APB3\_PNRES\_SOFT register (address 0x1300 4C2C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	AHB_TO_APB3_PNRES_SOFT	R/W	0x1	Reset for APB part of AHB_TO_APB3 bridge

**Table 232. APB4\_RESETN\_SOFT register (address 0x1300 4C30)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	APB4_RESETN_SOFT	R/W	0x1	Reset for AHB part of AHB_TO_APB4 bridge

**Table 233. AHB\_TO\_INTC\_RESETN\_SOFT register (address 0x1300 4C34)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	AHB_TO_INTC_resetn_soft	R/W	0x1	Reset for AHB_TO_INTC

**Table 234. AHB0\_RESETN\_SOFT register (address 0x1300 4C38)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	ahb0_resetn_soft	R/W	0x1	Reserved (It is not allowed to use this reset, as it cannot be disabled again afterwards)

**Table 235. EBI\_RESETN\_SOFT register (address 0x1300 4C3C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	ebi_resetn_soft	R/W	0x1	Reset for EBI

**Table 236. PCM\_PNRES\_SOFT UNIT register (address 0x1300 4C40)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	PCM_pnres_soft unit	R/W	0x1	Reset for APB domain of PCM

**Table 237. PCM\_RESET\_N\_SOFT register (address 0x1300 4C44)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	PCM_reset_n_soft	R/W	0x1	Reset for synchronous clk_ip domain of PCM

**Table 238. PCM\_RESET\_ASYNC\_N\_SOFT register (address 0x1300 4C48)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	PCM_reset_async_n_soft	R/W	0x1	Reset for asynchronous clk_ip domain of PCM

**Table 239. TIMER0\_PNRES\_SOFT register (address 0x1300 4C4C)**

Bit	Symbol	R/W	Reset Value	Description
31:1		-	-	Reserved
0	timer0_pnres_soft	R/W	0x1	Reset for Timer0

**Table 240. TIMER1\_PNRES\_SOFT register (address 0x1300 4C50)**

## 6. Functional description

The Clock Generation Unit contains:

- Clock switch block
- Configuration register block
- Reset and power block
- 12 MHz oscillator
- Two PLLs to generate audio sample frequencies and to generate system clock frequencies.

## 6.1 Clock switch box

### 6.1.1 Overview Switchbox Module

The switchbox consists of the following stages:

- A selection stage that allows a selection between a number of references into a number of base frequencies
- A spreading stage that for each base frequency provides individual enabling towards a set of module clocks.

These two stages are controlled via APB configuration registers. [Table 13–195](#) shows the switchbox configuration.

### 6.1.2 Selection stage

Selection Multiplexer switches allow each reference frequency to be passed to each base frequency.

Frequency switches allow safe run-time changes of base frequency selection.

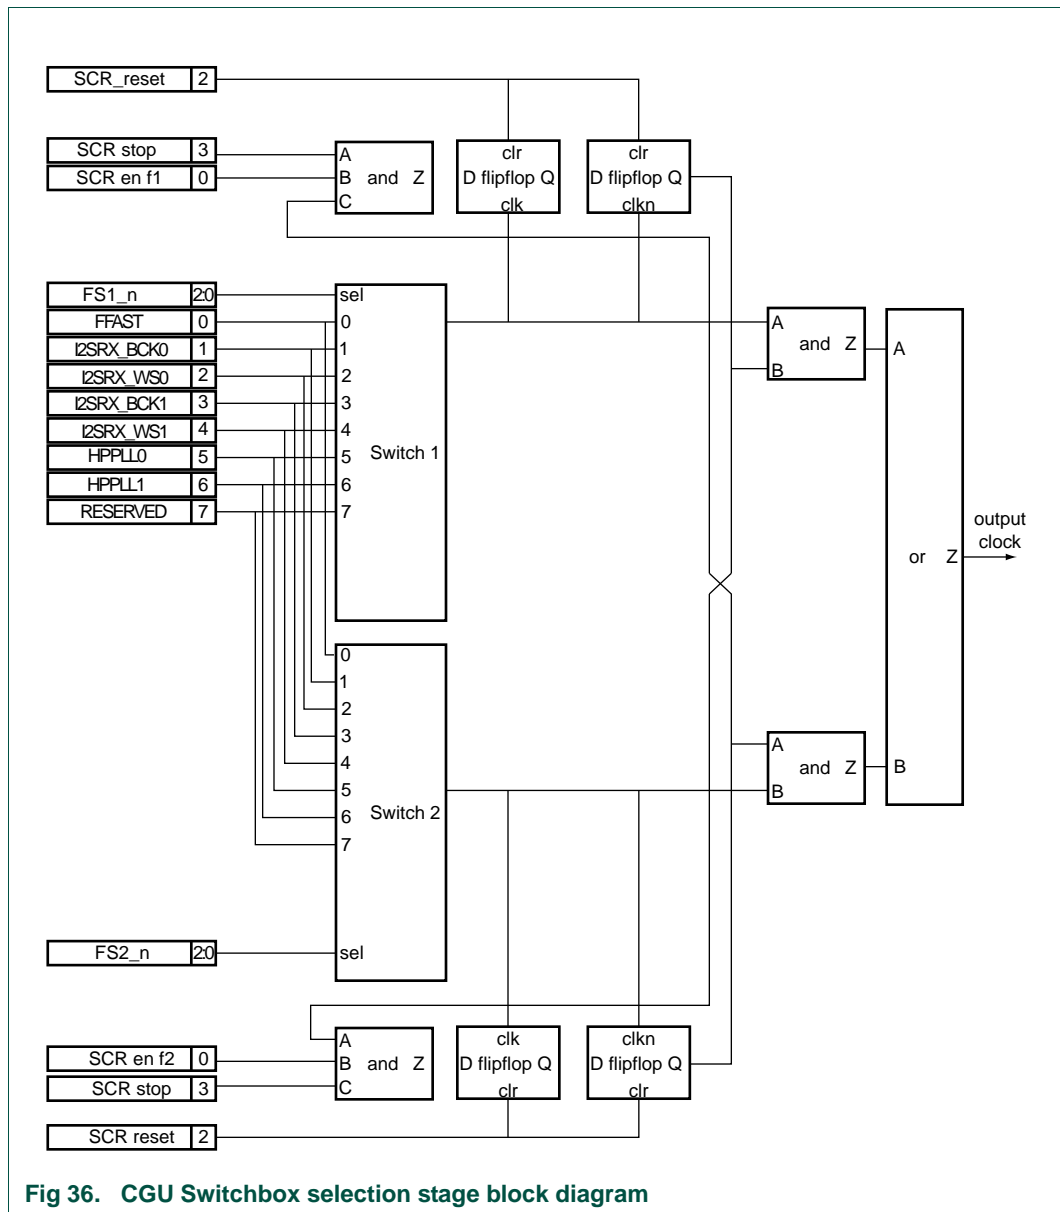

Fig 36. CGU Switchbox selection stage block diagram

A two path switch is used because there are no guaranteed clocks, making the use of state machines difficult. The frequency selector uses two multiplexers on all of the reference frequency inputs, resulting in the frequency F1 and F2. Two multiplexers are used to avoid glitches. Glitches can occur either, when multiplexing, or because the two frequencies are asynchronous (which they usually are) and the switching results in pulse clipping. The switch, as implemented above, solves these problems. This is done by selecting the new frequency on the multiplexer towards the switch side that is not activated, then by both removing the enable on one side, and activating the enable on the other side, switching take place. The construction of the switch is such that first base\_clk (the base frequency) is stopped when its level is low and after (at least) a complete period, at the falling edge of the new frequency, base\_clk will start to run again with this new frequency. The delay of at least a complete period in both the disabling and enabling ensures that no pulse width violations can occur.

Because it takes a certain amount of time to switch between F1 and F2, care must be taken when switching to or from very low-speed clocks. There may be a significant delay, in ARM clock cycles, between the clock switch programming, and the actual clock activation.

The SSR register can be used by software to wait for a clock switch to complete. When an active F1 or F2 is stopped externally (by stopping a PLL or as result of external activity) then the switch will enter a deadlock. (e.g.: When `f2enabled` is high, and F2 is stopped, then you cannot switch to F1.) This deadlock can be detected (after a software time out) by looking at the SSR register, both `F1STAT` and `F2STAT` will be '0'. To recover from this, the frequency switch must be reset in the software using the `RESET` bit of the `SCR` register.

All frequency select registers `FS1` and `FS2` in the clock switchbox are reset to 0, making `FFAST` as default clock source.

### 6.1.3 Spreading stage

- Each base frequency can be used to drive a set of module clocks.
- Each clock has its own enabling that can be controlled by a selectable fractional divider, via an (optional) external enable input, by its configuration register or with the `wake_up` signal.
- Fractional dividers on a base can be synchronized using the `BCR` registers.
- In test mode base clocks are overruled by a test clock.
- Positive and inverted clocks sharing the same enabling controls.

### 6.1.4 Fractional dividers

Fractional dividers give the possibility to generate derivatives of a base frequency. A derivative is generated by enabling/masking clock pulses and optionally stretching these pulses to obtain 50% duty cycle clock approximations can be done by software control.

The fraction `n/m` must always be smaller than one and greater than zero:

- When using clock stretching, the fraction must be smaller or equal to  $1/2$ .
- To obtain the best possible 50% duty cycle when clock stretching is used, `n/m` should equal a division by a 2 power value (i.e.:  $1/2$ ,  $1/4$ ,  $1/8$ , ..). Using other fractions will result in a best approximation.
- To minimize power consumption `madd` and `msub` should be chosen to have as many trailing zero's as possible (i.e. Shift values left until the bitwidth boundary reached).
- In case of multiple fractional dividers exist on a base and they need to run in sync use the base control register (`BCR0` - `BCR3`, `BCR7`) `fd_run` bit to disable the fractional dividers. Then program the dividers and set the base control register `fd_run` bit to high. This ensures that all fractional dividers on this base will start running at the same instant.

#### Example calculation of modula add (`madd`) and modula subtract (`msub`) values:

Say an input frequency of 13 MHz is given while a frequency of 12 MHz is required. In this case we want a frequency

$$f' = 12/13 * f$$

So  $n = 12$  and  $m = 13$ . This then gives

$$\text{madd} = m - n = 13 - 12 = 1$$

$$\text{msub} = -n = -12$$

Note that clock stretching is not allowed since  $n/m > 1/2$ .

In order to minimize power consumption  $\text{madd}$  and  $\text{msub}$  must be as large as possible. The limit of their values is determined by the  $\text{madd}/\text{msub}$  bit width. In this case  $\text{msub}$  is the largest value, in order to express  $-12$ , five bits are required. However since  $\text{msub}$  is always negative the fractional divider does not need the sign bit, leaving 4bits. If  $\text{madd}/\text{msub}$  bit width has been set to say 8 bits, it is allowed to shift 4 bits, giving:

$$\text{msub}' = -(12 \ll 4) = -12 \times 2^4 = -12 \times 16 = -192$$

$$\text{madd}' = 1 \ll 4 = 2^4 = 16$$

### 6.1.5 Dynamic fractional dividers

The dynamic fractional dividers allow hardware (mostly AHB busmasters) to directly control the speed of the AHB bus. This will give several advantages:

- Hardware will decide the most optimum AHB frequency. Software engineers do not have to decide the optimum AHB frequency for their application. The Hardware will do this as efficiently as possible.
- The fast clock will only be needed when data needs to be transferred. This means that when data does not need to be transferred, the AHB bus and its connected IP will consume very little power during IDLE modes.

The operation is as follows:

- All the fractional dividers of SYS-base have 'partner' registers.
- The register 'DYN\_FDC' for the slow-speed clock-setting and the 'DYN\_SEL' register for the selection of AHB busmasters that can trigger the dynamic operation.

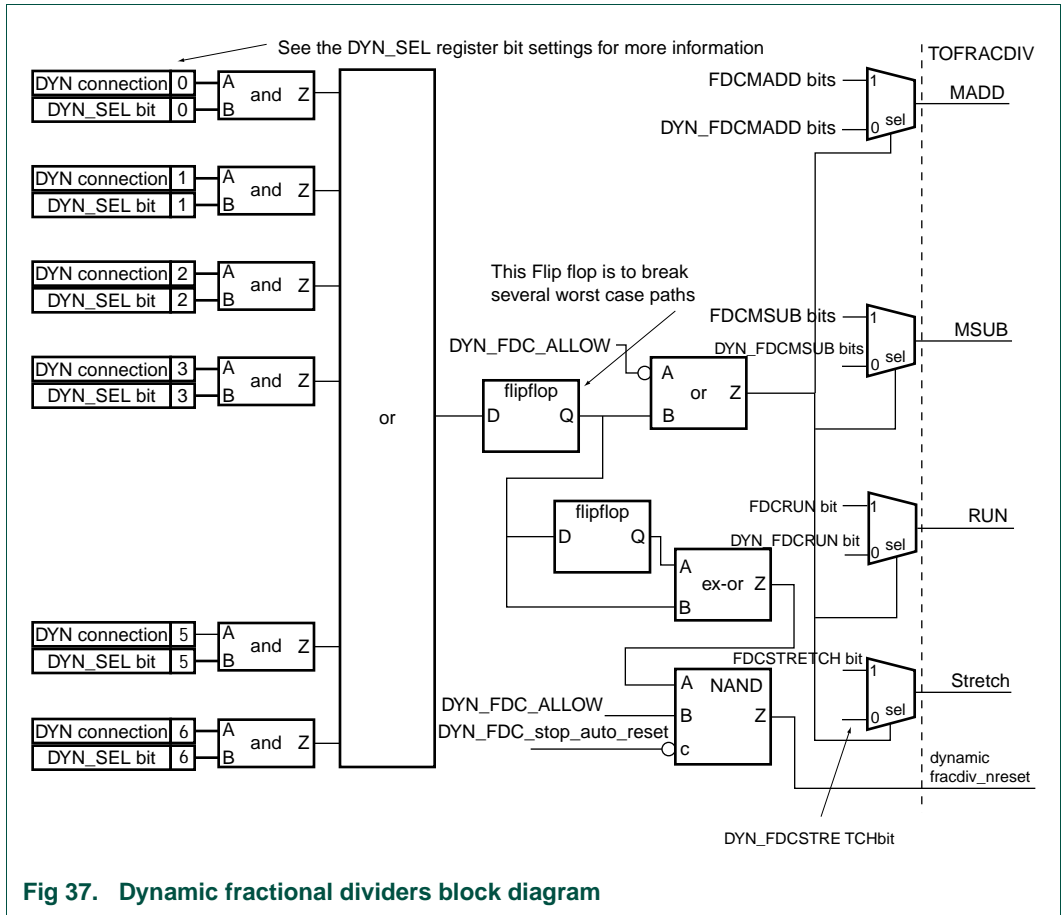

When these partner registers are not programmed, the fractional dividers run in normal mode. The values programmed in the normal 'FDC' register determine the speed of the fractional divider, and this speed remains the same until re-programmed.

However, when bit 'DYN\_FDC\_ALLOW' of a 'DYN\_FDC' register is set, then the AHB busmasters can control the speed of the fractional divider to either a 'slow' or a 'high' speed setting.

When this 'DYN\_FDC\_ALLOW' bit is set, the 'FDC' register is then the register for the 'high' speed setting, register 'DYN\_FDC' is the register for the 'slow' speed setting.

In register 'DYN\_SEL' each 'set' bit enables an AHB busmaster to set the fractional divider to the 'high' speed setting. As shown in [Figure 13-37](#), the logical AND operation between this enable signal (DYN\_SEL bit) and the signal which comes from the AHB master (DYN Connection) will select the FDC MADD bits. The result of this is that the fractional divider will be configured for a 'high' speed setting. In this case has DYN\_FDC\_ALLOW to be activated.

When any of the selected inputs change from high-to-low or from low-to-high a reset may be generated automatically to the fractional divider. This forces the fractional divider to re-program itself to the new value, to improve the speed of the transition from low to high speed operation.

This also synchronizes dynamic fractional dividers 0 and 1 with each other when they are both programmed with the same selection bits. This is required when the CPU and the AHB bus are both programmed behind a different fractional divider.

When required, this dynamic reset behavior can be disabled by setting bit 'STOP\_AUTO\_RESET' of the DYN\_FDC register.

### 6.1.6 External enabling

External enabling provides the ability to use signals from outside the switchbox to enable the module clocks. These signals are latched with the base reference to ensure correct timing.

This functionality is typically used to reduce power consumption by disabling a clock whenever it is not required. It allows clock control from a module level as opposed to the power control register that represents clock control from the system level.

### 6.1.7 Wake\_up feature

To support power modes a clock can be made controllable with the wake\_up signal via its PCR wakeup\_en bit. When active this clock will then, together with all other clocks that have the wakeup\_en bit set, be disabled when wake\_up becomes low and enabled when wake\_up becomes high.

Through the wake\_up feature, a group of clocks can be made controllable with a single signal, wake\_up. The intention of this signal is, when used in combination with a wake\_up event detection mechanism and a power mode selection, it will then disable clocks that are wake\_up enabled until a wake\_up event has occurred.

Clock enabling/disabling takes two to three base periods to take effect.

The wake\_up feature will be disabled for a clock when its auto bit in its pcr register is set to '0'.

## 6.2 Configuration register block

### 6.2.1 Watchdog identification register

To find out whether a reset was caused by an external 'RSTIN\_N', or a watchdog reset, a special 'wd\_bark' register is used. When a watchdog reset has occurred, the 'wd\_bark' register will be 1 after reset.

### 6.2.2 Controlling the frequency sources

There are two types of analog devices in the CGU. These are used as frequency sources:

- 12 MHz Oscillator
- Two PLLs: HPPLL (Phase Locked Loop).

### 6.2.3 Programming PLLs

To program a Phase Locked Loop (PLL) device, do the following sequence:

1. Disable the device by activating the power down mode or place it in reset mode when the module is digital
2. Set the correct operating mode and multiplication/division factor
3. Enable the device by placing it in functional mode
4. Wait until the generated frequency is stable.

When re-programming a frequency source, make sure that no clock is being generated from it.

## 6.3 Reset and power block

Power up reset is initiated by the external signal RSTIN\_N, or by the internal signal 'wdr', from the watchdog. The RSTIN\_N signal is intended as a 'battery insertion' type of reset, active low. Both the 'RSTIN\_N' and the 'wdr' initialize the clockgen module into its reset state. A 'vddalways\_resetrn' reset signal is created that is stretched until the first rising 'pclk' edge after the power up signal has become inactive. 'vddalways\_resetrn' activates the other reset signal(s), defined as reset domains.

The CGU is able to generate as many resets, synchronized to specific clock domains, as required. All resets domains specified have a re-synchronization clock input. This is used to keep the reset active until the second rising edge of the resync clock, after 'vddalways\_resetcn' has become inactive. If the reset is asynchronous, it is kept active for another half clock cycle to prevent hold violations. The reset can be selected either as active high or active low polarity. It can also be selected for synchronous or asynchronous use. The implementation difference is with the handling of the signal during scan test mode and its deactivation timing. During production test (scantestmode=1), all asynchronous reset outputs are directly, asynchronously connected to RSTIN\_N. All synchronous signals remain controlled by the synchronization flip flops. Optionally a software reset, active low, can be generated. This will add a configuration register, the signal is given the 'AND' command with the normal reset and serves as data input to the synchronization flip flops.

### 6.3.1 Clock disabling

By means of the powermode register it is possible to disable module clocks using the wake\_up mechanism. Clocks that are disabled in this way will be reactivated when a wake\_up event occurs.

Clock disabling is done by first, enabling the wake\_up mechanism for a set of clocks by setting the 'wake\_en' bit in the clk's power control register. Then by writing 2'b11 in the powermode register, clock disabling is initiated, resulting in following sequence of actions:

1. Masters for which disabling controls are provided will be denied bus access.
2. Wakeup enabled clocks will disappear after their second active edge.
3. When wake\_up become high (a wake\_up event occurred) the power status register is asynchronous reset into normal mode.
4. Disabled clocks become active again after two clock periods.

### 6.3.2 AHB Master disabling feature

The CGU template offers support for individual AHB master disabling. AHB Masters must not be performing bus access when put into clock disable mode. To ensure the master is removed from the bus a disable request is generated. This signal is used by the bus (ahb\_multilayer) to deny any new access requests. After the master has finished its current request a disable grant is generated by the bus. The internal wakeup\_i signal going to the clock switchbox is allowed to become low when all grants have been received.

The following is a detailed overview of the clk disable mechanism sequence:

1. Clock disabling is preceded by a software setup in which for a set of clocks the wakeup\_en control bit is set in their PCR (see clock switchbox). It also configures the event\_router to respond to certain events that can generate a wakeup towards the CGU.
2. The software then activates the clock disabling by writing b11 to the powermode register.
3. The CGU will before entering powermode ensure that all masters for which the wakeup\_en control bit has been set and that support master disabling are no longer performing bus access. To do this it sets the corresponding master\_disable\_req signal high.

4. The multilayer uses the disable request to mask bus access requests from the master. The master is allowed to finish its current activities, but will not be able to initiate a new access.
5. When the master is no longer performing access (this might be immediately) the bus will return a master\_disable\_grant signal to the CGU.
6. As soon as all masters, for which the wakeup\_en control bit has been set, are disabled the clocks will be disabled.
7. Clocks will become quiescent after two of their active edges.
8. When a wakeup event occurs the wake\_up signal output of the event router becomes high and clears (asynchronously) the power mode register in the CGU, thereby re enabling the clocks after two of their active edges.
9. One cycle after a master clock starts running its master\_disable\_req signal becomes low and the bus will again process its access requests.

## 6.4 12 MHz oscillator

The oscillator is a 50 MHz Pierce crystal oscillator with amplitude control. It can be used in many applications e.g. as a digital reference for digital circuits, A/D and D/A clocking, etc. It is a robust design and can be used across a large frequency range.

The features of the 12MHz oscillator are as follows:

- On chip biasing resistance
- Amplitude controlled
- Large frequency range: 1 MHz to 50 MHz
- Slave mode
- Power down mode
- Bypass test mode.

### 6.4.1 Oscillation mode

In oscillation mode, the oscillator gain stage can have a normal or large transconductance, determined by the hf pin. A large transconductance is required for higher oscillation frequencies, higher series resistance of the crystal and higher external load capacitors. In table below the values of the external components for frequency ranges between 1 MHz and 20 MHz are given.

**Table 302. Crystal oscillator interface register**

Oscillation frequency $f_c$	Max. series resistance $R_s$	External load capacitors $C_{x1}$ , $C_{x2}$
12 MHz	< 160	18 pF, 18 pF
	< 160	39 pF, 39 pF

### 6.5 PLLs for generating audio clocks and system clocks (HPPLL0 and HPPLL1)

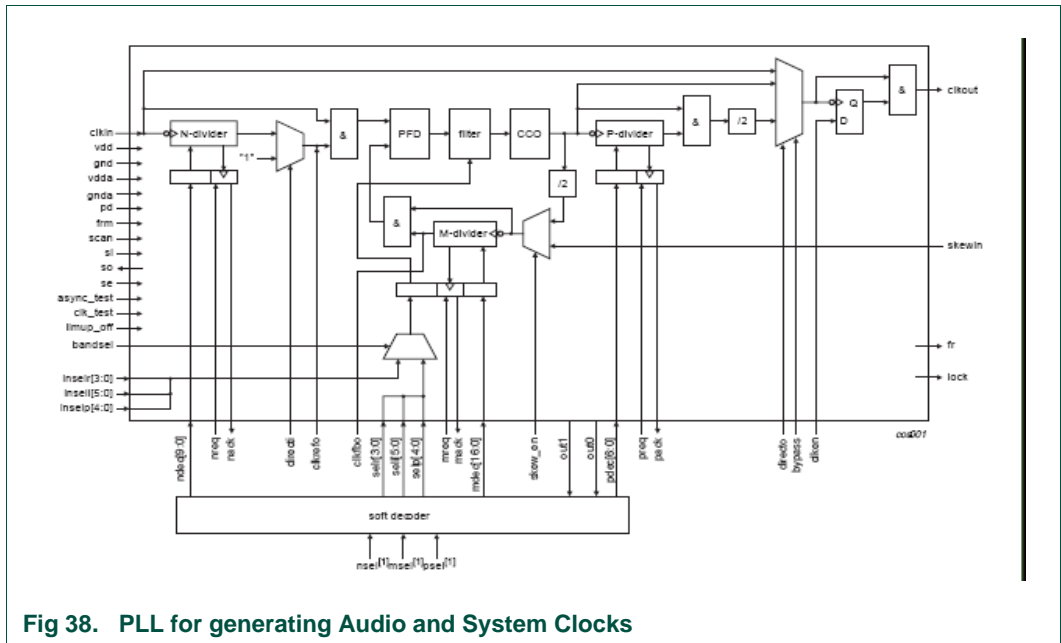

Fig 38. PLL for generating Audio and System Clocks

#### 6.5.1 Functional description of the PLL

The clock input has to be fed to pinclkkin. Pin clkout is the PLL clock output. The analog part of the PLL consists of a Phase Frequency Detector (PFD), filter and a Current Controlled Oscillator (CCO). The PFD has two inputs, a reference input from the (divided) external clock and one input from the divided CCO output clock. The PFD compares the phase/frequency of these input signals and generates a control signal when they do not match. This control signal is fed to a filter that drives the CCO. The PLL contains three programmable dividers: pre-divider (N), feedback-divider (M) and post-divider (P). Every divider contains a bus (xsel[n:0] in which x is n, m or p) to load a divider ratio. The dividers also possess the handshake signals xreq and xack to select a new divider ratio. The PLL contains a lock detector (use the lock pin to monitor whether or not the PLL is in lock, so don't use this pin to reset a system) that measures the phase difference between the rising edges of the input and feedback clocks. Only when this difference is smaller than the so called 'lock criterion' for more than seven consecutive input clock periods, the lock output switches from low to high. A single too large phase difference immediately resets the counter and causes the lock signal to drop (when it was high). Requiring seven phase measurements in a row to be below a certain figure ensures that the lock detector will not indicate lock until both the phase and frequency of the input and feedback clocks are very well aligned. This effectively prevents false lock indications, and thus ensures a glitch free lock signal. To avoid frequency hang-up, the PLL contains a frequency limiter. This feature is built in to prevent the CCO from running too fast, this can occur when, for example, a wrong feedback-divider (M) ratio is applied to the PLL. For analog test purposes there are also the pins clkfbo and clkrefo to monitor the output of the feedback and pre-divider.

## 6.5.2 Use of PLL operating modes

Table 303. PLL operating modes

Mode	HP0/1_Mode bit settings:							
	Pd	Clken	Bypass	DirectI	DirectO	Skew_en	frm	scan
1: Normal	0	1	0	1/0	1/0	0	0	0
2: Reserved	0	1	0	1/0	1/0	1	0	0
3: Power Down	1	x	x	x	x	x	x	x
4: Bypass	0	0/1	1	x	x	x	0	x
5: Reserved	0	x	0	x	x	x		
6: Scan	1	x	x	x	x	x	x	1
7: Enable	x	0/1	x	x	x	x	x	x

### 6.5.2.1 Normal Mode

Mode 1 is the normal operating mode.

The pre- and post-divider can be selected to give:

- mode 1a: Normal operating mode without post-divider and without pre-divider
- mode 1b: Normal operating mode with post-divider and without pre-divider
- mode 1c: Normal operating mode without post-divider and with pre-divider
- mode 1d: Normal operating mode with post-divider and with pre-divider

To get at the output of the PLL (clkout) the best phase-noise and jitter performance, the highest possible reference clock (clkref) at the PFD has to be used. Therefore mode 1a and 1b are recommended, when it is possible to make the right output frequency without pre-divider.

By using the post-divider the clock at the output of the PLL (clkout) the divider ratio is always even because the divide-by-2 divider after the post-divider.

Table 304. DirectI and DirectO bit settings in HP0/1\_Mode register

Mode	DirectI	DirectO
1a	1	1
1b	1	0
1c	0	1
1d	0	0

### 6.5.2.2 Mode 1a: Normal operating mode without post-divider and without pre-divider

In normal operating mode 1a the post-divider and pre-divider are bypassed. The operating frequencies are:

$$F_{out} = F_{cco} = 2 \times M \times F_{in} \quad (275 \text{ MHz} \leq F_{cco} \leq 550 \text{ MHz}, 4 \text{ kHz} \leq F_{in} \leq 150 \text{ MHz})$$

The feedback divider ratio is programmable:

- Feedback-divider M (M, 1 to 2<sup>15</sup>)

**6.5.2.3 Mode 1b: Normal operating mode with post-divider and without pre-divider**

In normal operating mode 1b the pre-divider is bypassed. The operating frequencies are:

$$F_{out} = F_{cco} / (2 \times P) = (M / P) \times F_{in} \wedge (275 \text{ MHz} \leq F_{cco} \leq 550 \text{ MHz}, 4 \text{ kHz} \leq F_{in} \leq 150 \text{ MHz})$$

The divider ratios are programmable:

- Feedback-divider M (M, 1 to  $2^{15}$ )
- Post-divider P (P, 1 to 32)

**6.5.2.4 Mode 1c: Normal operating mode without post-divider and with pre-divider**

In normal operating mode 1c the post-divider with divide-by-2 divider is bypassed. The operating frequencies are:

$$F_{out} = F_{cco} = 2 \times M \times F_{in} / N \wedge (275 \text{ MHz} \leq F_{cco} \leq 550 \text{ MHz}, 4 \text{ kHz} \leq F_{in}/N \leq 150 \text{ MHz})$$

The divider ratios are programmable:

- Pre-divider N (N, 1 to 256)
- Feedback-divider M (M, 1 to  $2^{15}$ )

**6.5.2.5 Mode 1d: Normal operating mode with post-divider and with pre-divider**

In normal operating mode 1d none of the dividers are bypassed. The operating frequencies are:

$$F_{out} = F_{cco} / (2 \times P) = M \times F_{in} / (N \times P) \wedge (275 \text{ MHz} \leq F_{cco} \leq 550 \text{ MHz}, 4 \text{ kHz} \leq F_{in}/N \leq 150 \text{ MHz})$$

The divider ratios are programmable:

- Pre-divider N (N, 1 to 256)
- Feedback-divider M (M, 1 to  $2^{15}$ )
- Post-divider P (P, 1 to 32)

**6.5.2.6 Mode 2: Reserved**

Reserved for future use.

**6.5.2.7 Mode 3: Power down mode (pd)**

In this mode (pd = '1'), the oscillator will be stopped, the lock output will be made low, and the internal current reference will be turned off. During pd it is also possible to load new divider ratios at the input buses (msel, psel, nsel). Power-down mode is ended by making pd low, causing the PLL to start up. The lock signal will be made high once the PLL has regained lock on the input clock.

**6.5.2.8 Mode 4: Bypass mode**

In the bypass mode the input clock (clk<sub>in</sub>) will be bypassed to the output (clk<sub>out</sub>) of the PLL. Precaution has to be taken that no spikes will occur at the output of the PLL (clk<sub>out</sub>) by switching into and out of the bypass mode. To avoid spikes the output has to be disabled during switching into and out of the bypass mode. This can be done with pin clken.

**6.5.2.9 Mode 5: Reserved**

Reserved for future use.

**6.5.2.10 Mode 6: Test mode for digital part**

In this mode the digital logic in the PLL can be scanned on faults. All the digital circuitry in the PLL is connected to one scan-chain with the input and output pins `si` and `so` and the enable pin `se` and test clock `clk_test`. By setting the PLL into test mode (`scan = '1'`), the test clock is connected to the scan-chain. During scan mode the PLL has to be set into power down mode. To test the synchronous circuitry the Shift Mode and Normal Mode is needed. The asynchronous circuitry can be tested with the Shift Mode and the Async Mode.

**6.5.2.11 Mode 7: Enable mode**

In the enable mode the output `clkout` of the PLL is enabled. When `clken = '0'` the output of the PLL is low (`clkout = '0'`). Precaution is already taken that no spikes will occur at the output of the PLL (`clkout`) by switching into and out of the enable mode.

**6.5.3 Settings for Audio PLL**

[Table 13–305](#) shows the divider settings used for configuring a certain output frequency  $F_{out}$  by a certain sample frequency  $F_s$  for the Audio PLL.

**Table 305. Audio PLL divider ratio settings for 12 MHz**

$F_s$ (kHz)	$F_{out}$ (MHz)	$F_{CCo}$ (MHz)	Ndec	Mdec	Pdec	SELR	SELI	SELP
256 $F_s$ (Settings for Class-AB)

6.6 Typical performance settings

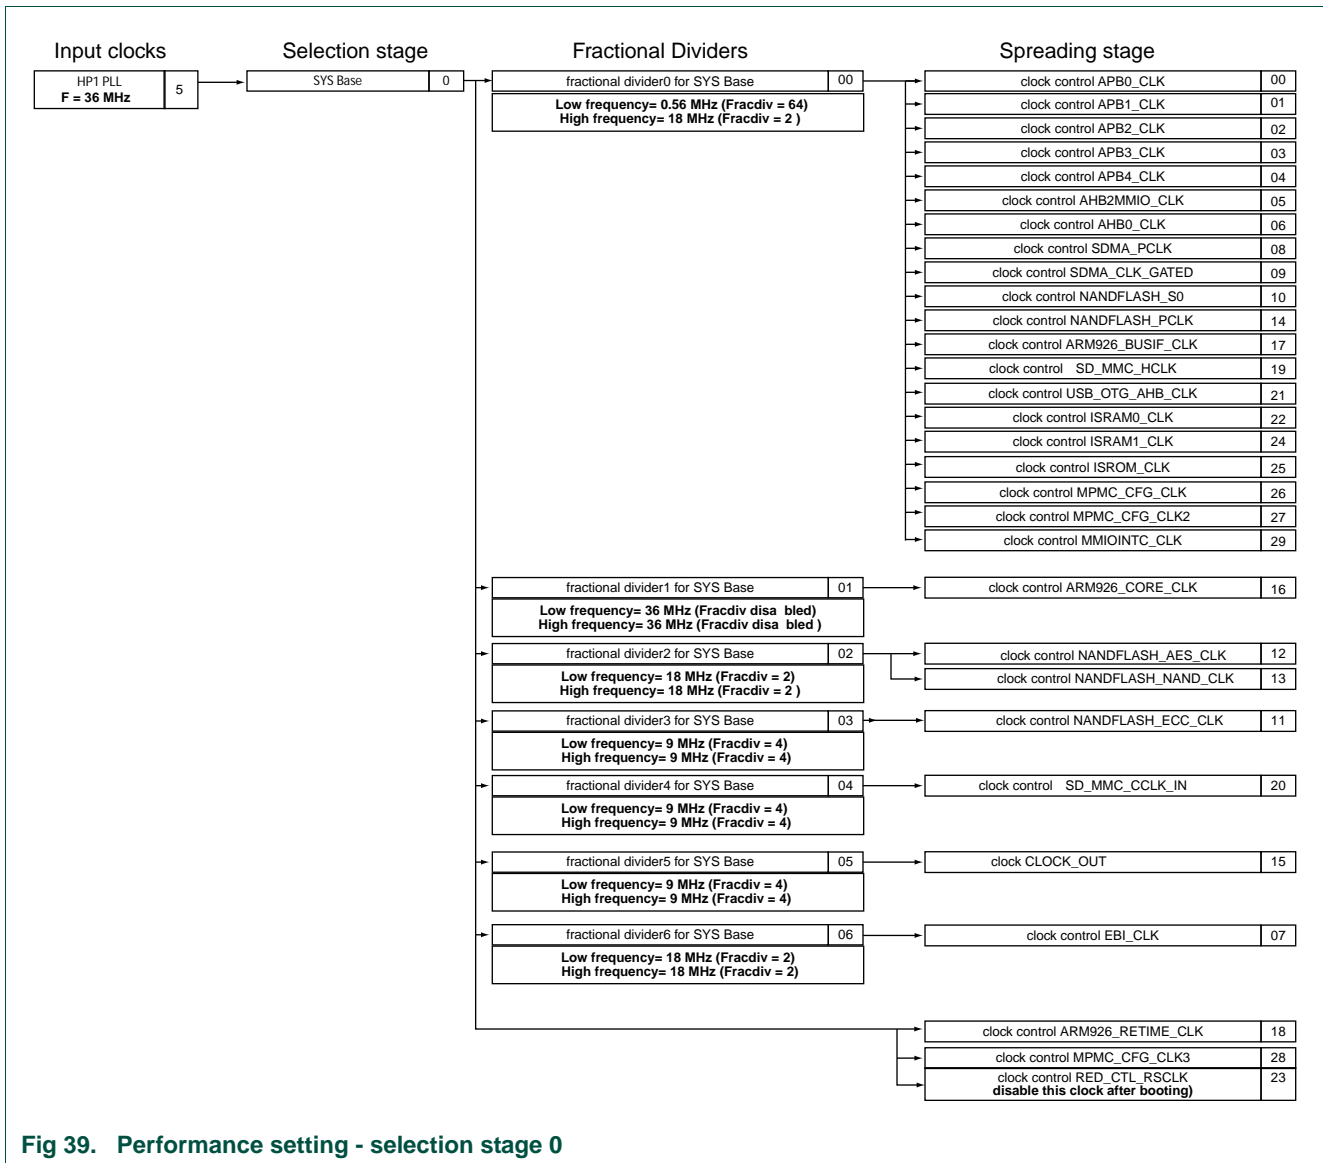

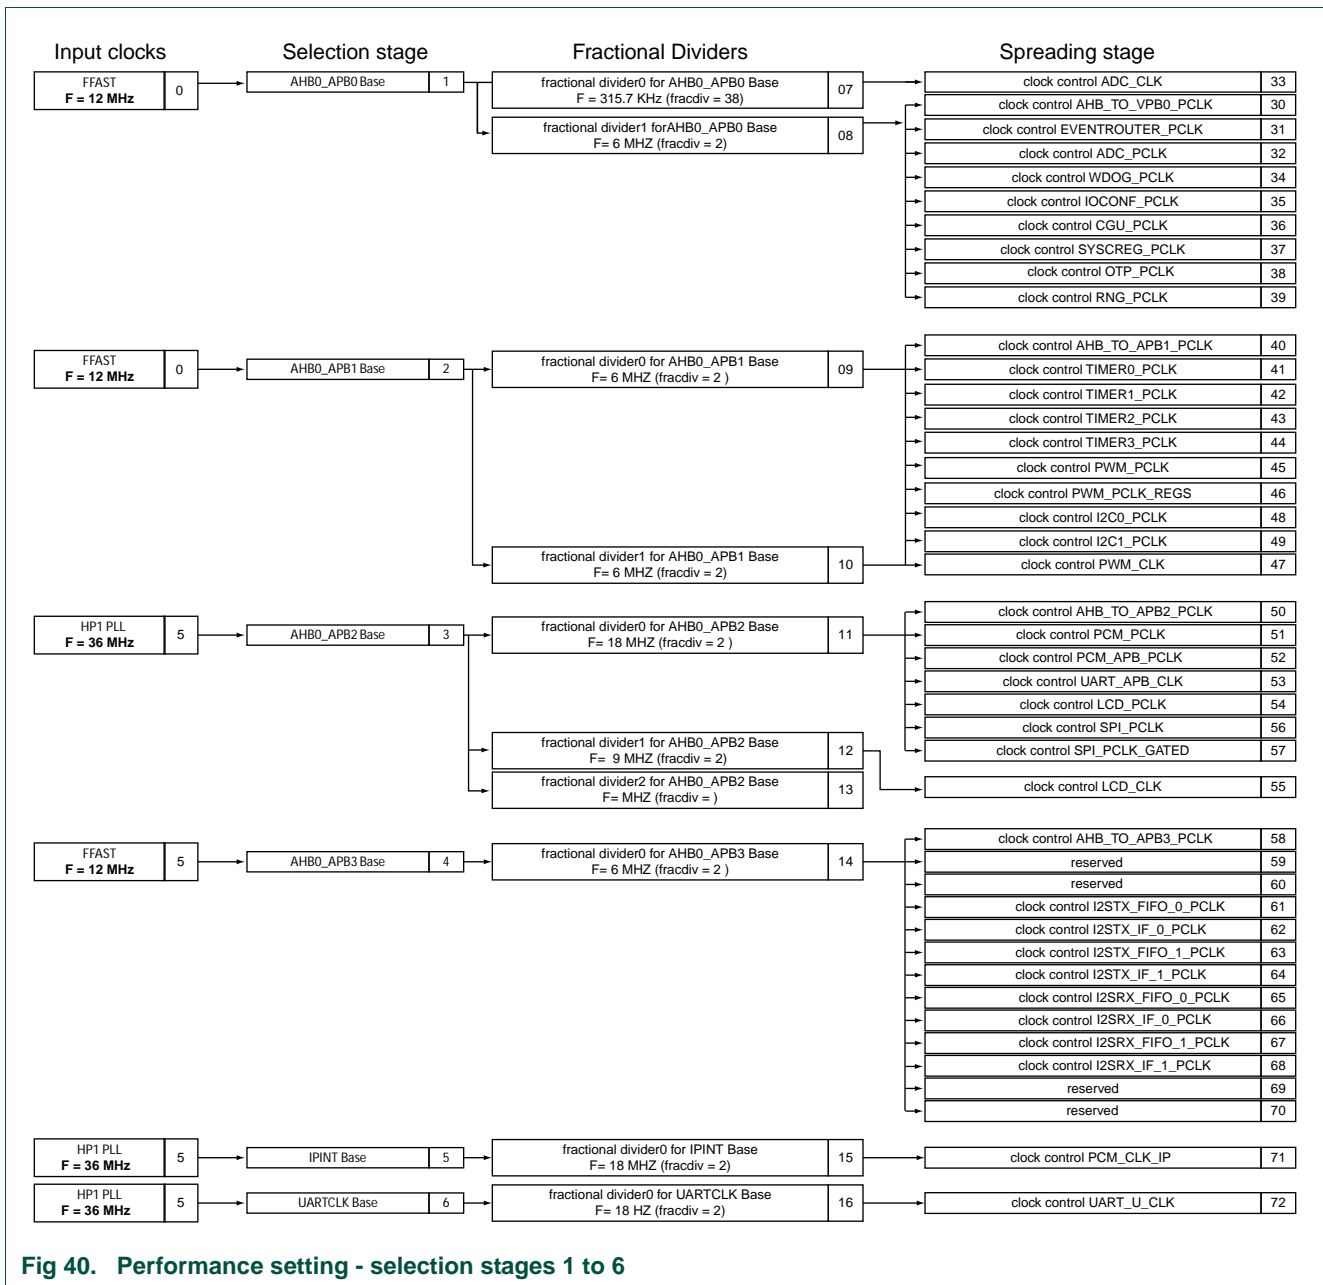

Fig 39. Performance setting - selection stage 0

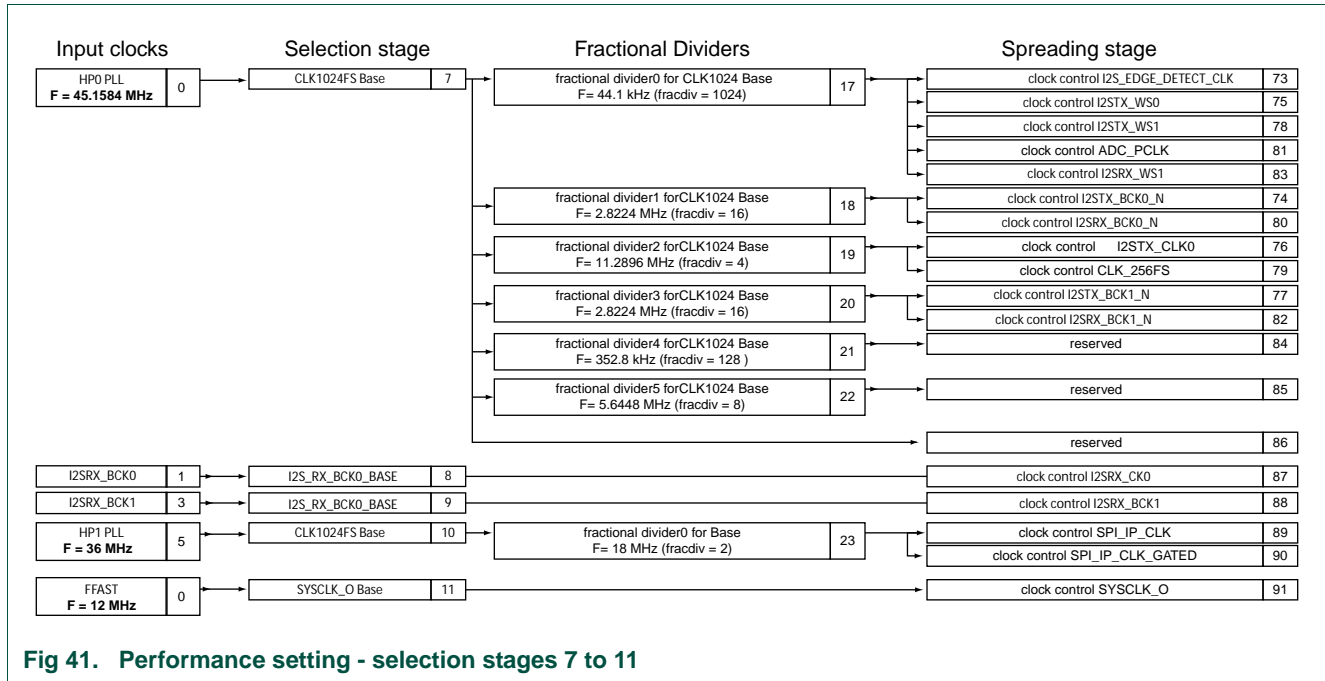

Fig 41. Performance setting - selection stages 7 to 11

## 7. Power optimization

The CGU supports variable clock scaling and external clock enabling. These items reduce power dissipation.

Clocks of blocks that are not used in a certain application can be disabled by the CGU. The same is true for PLLs and base.

## 8. Programming guide

### 8.1 Maximum frequencies

Setting the ARM speed at a specific voltage also has implications to the AHB bus speed settings. AHB bus speed has to be a fractional (integer) division of the ARM speed but is always limited by the maximum AHB speed. The maximum frequencies of the AHB Multi-layer and the ARM926 are shown in [Table 13-307](#) for different voltages.

Table 307. Maximum clock speed AHB Multi-layer and ARM at worst-case silicon corner and at 85 °C

Voltage (V)	Maximum speed in MHz			
	0.9	1.0	1.1	1.2
AHB Multi-layer speed	41	57	73	90
ARM926 speed	90	130	170	180

### 8.2 Changing fractional dividers values

Steps to follow for changing the fractional dividers values when base frequency is lower or equal than the maximum possible frequency of one of the clocks:

1. Clear the BCR bit of the base, that consists the fractional divider(s), that you want to change. (Reset all fractional dividers of the base is not needed. This will be done by BCR bit).
2. Change the divider values of the fractional dividers.
3. Set the BCR bit of the base, that consists the fractional divider(s), that are changed.

Steps to follow for changing the fractional dividers values when base frequency is higher than the maximum possible frequency of one of the clocks:

1. Switch base to 12 MHz clock
2. Clear the BCR bit of the base, that consists the fractional divider(s), that you want to change. (Reset all fractional dividers of the base is not needed. This will be done by BCR bit)
3. Change the divider values of the fractional dividers
4. Set the BCR bit of the base, that consists the fractional divider(s), that are changed
5. Switch base to the required reference clock.

## 8.3 Programming variable clock-scaling

### 8.3.1 Programming order variable clock-scaling

1. Set the BCR bit of Base 0 to '0x0'.
2. Program all AHB IP to fractional divider 0.
3. Deselect these clocks from the fractional divider
  - AHB\_MPMC\_CFG\_CLK3
  - ARM926\_CORE\_CLK
  - ARM926\_RETUNE\_CLK
4. Set the PCR EN\_OUT bit of the following clocks:
  - ARM926\_BUSIF\_CLK
  - AHB\_MPMC\_CFG\_CLK (This is for the refresh logic for the SDRAM)
5. Set the RUN-bit of fractional divider 0 when the clock needs to be divided. When fractional divider must be the same as the SYS\_BASE\_CLK, then keep the RUN bit disabled.
6. Program the DYN\_SEL register of dynamic fractional divider 0 with all the masters that may enable the high-speed clock.
7. Program the DYN\_FDC register of fractional divider 0 (AHB) to the slow clock value and enable it by setting the DYN\_FDC\_ALLOW bit.
8. Program dynamic fractional divider register DYN\_FDC of fractional divider 1 with the same settings as FDC, but don't set the DYN\_FDC\_ALLOW bit.
9. When the ARM926 needs to run slower than the SYS\_BASE\_CLK then:
  - Program the ARM926 clock (ARM926\_CORE\_CLK) to fractional divider 1
  - Program fractional divider 1. Set the RUN bit when the ARM926 clock needs to be divided
  - Program the DYN\_SEL bits of dynamic fractional divider 1 with the same value as DYN\_SEL of dynamic fractional divider 0

- When you want to run the ARM always on the same frequency, program register DYN\_FDC of fractional divider 1 with the same settings as FDC and set the DYN\_FDC\_ALLOW bit. Otherwise program a different value in DYN\_FDC and set the DYN\_FDC\_ALLOW bit.
10. Set the BCR register of SYS\_BASE (BCR0) to 0x1. The clock-shop is now running with dynamic frequencies
  11. Because of the now unpredictable average clock-speed of the AHB bus, the refresh of the SDRAM needs to be programmed using the alternative refresh generator. This generator can be programmed inside the 'syscreg' block, register 'mpmc\_testmode0'. See the programming example below.

**Remark:** The alternative refresh register needs to be re-calculated when the base frequency is changed.

It is very important that when both fractional dividers are enabled, it is mandatory to clear the BCR register before reprogramming fractional dividers.

When just fractional divider 0 is enabled, it can be reprogrammed on-the-fly.

One has to take the following into account for the CGU driver:

- Fractional divider should be selected but not enabled when fractional divider setting = '0' (otherwise dynamic clock scaling does not work).

### 8.3.2 Programming example for variable clock-scaling

```
#define FDID_FOR_AHB_IP 0
#define FDID_FOR_ARM926 1

clkid = vhGetClockId(VHISRAM_ID, 0, 0);
baseid = clkid2baseid(clkid);
    // we work on the base_id of the SRAM (and ARM, and AHB...)

// Disable all fracdivs of base 0
SWITCHBOX_REGS -> base_bcr[baseid]=0;

//Setup fracdivs. Clear first
vhClkFracDivClearAll();

vhClkFracDivConfig_fixed_fdid(FDID_FOR_AHB_IP, 1, 4, 1, 1); // divide clock by 4

for (i=baseid2firstclk(baseid); i<= baseid2lastclk(baseid); i++) {vhClkFracDivSelect(i,
    FDID_FOR_AHB_IP);
}

vhClkFracDivDeselect(CGU_SWITCHBOX_AHB_MPMC_PL172_CFG_CLK3_ID); // to allow the
    alternative refresh generator to run faster
vhClkFracDivDeselect(CGU_SWITCHBOX_ARM926EJS_CORE_CLK_ID); // to allow the ARM to run
    faster
vhClkFracDivDeselect(CGU_SWITCHBOX_ARM926EJS_RETIME_CLK_ID); // to allow the retimer
    of the ARM9 to work.
```

```
vhPrintfMessage("Setup CGU pcr register;\n");
SWITCHBOX_REGS -> clk_pcr[CGU_SWITCHBOX_ARM926EJS_BUSIF_CLK_ID] |= PCR_ENOUT_EN;
SWITCHBOX_REGS -> clk_pcr[CGU_SWITCHBOX_AHB_MPMC_PL172_CFG_CLK_ID] |=
PCR_ENOUT_EN;

//Setting dynamic ARM9 half speed to half the speed
vhClkFracDivConfig_fixed_fdid(FDID_FOR_ARM926, 1, 2, 1, 1);
vhClkFracDivSelect(CGU_SWITCHBOX_ARM926EJS_CORE_CLK_ID, FDID_FOR_ARM926);

// AHB dynamic clock

vhDynFracDivSelect(FDID_FOR_AHB_IP,0xffffffff); // all masters can trigger fast speed
vhClkFracDivConfig_Dyn(FDID_FOR_AHB_IP, 1, 40,0,1,1); // divided by 40!

// ARM926 dynamic clock
vhDynFracDivSelect(0x1,0xffffffff); // all masters can trigger fast speed
vhClkFracDivConfig_Dyn(FDID_FOR_ARM926, 1, 2,0,1,1); // devided by 2

// Enable the dynamic clocks
SWITCHBOX_REGS -> base_bcr[baseid]=1;

vhPrintfMessage("System to 96 Mhz\n");
vhClkReferenceSelect(VH_PWRCLK_SYS_BASE, CGU_FIN_SELECT_FFAST);
vhClkLpPllConfig (0,CGU_FIN_SELECT_FFAST, 7, 0, 1); // 96 Mhz
vhClkReferenceSelect(VH_PWRCLK_SYS_BASE, CGU_FIN_SELECT_LPPLL0);

// Use the alternative refresh generator to generate a AHB clock-indendent refresh
    towards the SDRAM
// The base clock has just been set to 96 Mhz. The hyphotatical SDRAM has a
    auto-refresh timing of 15 us.
// Calculation: 96 Mhz = 10.42ns
// 15 us auto refresh /10.42ns = 1440 clocks.

gpSYSCREG_REGS->mpmc_testmode0=0x1000 + (1440/16);
// Enable bit + 1260 base clocks @ 96 Mhz = 15 us

// This is to set the dynamic clock temporarily high during refreshes. This will
    improve power on certain SDRAMs
gpSYSCREG_REGS->mpmc_testmode1=0x20; // Dynamic activity of 32 clock cycles
```

## 1. Introduction

The LPC315x contains a special timer module that can be used to generate a software reset in case of CPU/software crash.

The watchdog timer can also be used as an ordinary timer.

### 1.1 Features

This module has the following features:

- Generates a chip-wide reset request when its programmed time-out period has expired, in the event of a software or hardware failure.
- Watchdog counter can be reset by a periodical software trigger.
- After a reset, a register will indicate whether a reset has occurred because of a watchdog generated reset.
- Apart from watchdog functionality, it can also be used as a normal interval timer.

## 2. General description

### 2.1 Clock signals

**Table 308. Clock Signals of the WatchDog Timer**

Clock Name	Acronym	I/O	Source/Destination	Description
WDOG_PCLK	PCLK	I	CGU	Main clock for WatchDog timer block

**Remark:** The clock is asynchronous to the AHB Clock

### 2.2 Interrupt requests

The Watchdog Timer module has 2 interrupt request signals. The first is connected to the Event Router while the second is connected to the CGU.

**Table 309. Interrupt Requests of the WatchDog Timer**

Name	Type	Description
M0	O	Soft WatchDog interrupt to Event Router.
M1	O	Hard WatchDog Reset to CGU.

### 2.3 Reset signals

The CGU provides an APB Asynchronous Reset signal (PNRES). It is active low.

### 3. Register overview

**Table 310. Register overview: WDT (register base address 0x1300 2400)**

Name	R/W	Address Offset	Description
IR	R/W	0x00	Interrupt Register. The IR can be written to clear interrupts. The IR can be read to identify which of two possible interrupt sources are generating an interrupt.
TCR	R/W	0x04	Timer Control Register. The TCR is used to control the Timer Counter and Prescale Counter functions. The Timer Counter and Prescale Counter can be disabled or reset through the TCR.
TC	R	0x08	Timer Counter. The TC is incremented every PR+1 cycles of pclk. The TC is controlled through the TCR.
PR	R/W	0x0C	Prescale Register. This Prescale Register (PR) is an 32 bits register. It specifies the maximum value (MAXVAL) for the prescale Counter (PC). It allows the user to specify that the TC be incremented every PR+1 cycles of pclk.
PC	R	0x10	Prescale Counter. The PC is increment every WDOG_PCLK cycle when timer counter is enabled in TCR register.
MCR	R/W	0x14	Match Control Register. The MCR is used to control if an interrupt is generated and if the TC is reset when one of the Match Registers matches the value in the TC.
MR0	R/W	0x18	Match Register 0. The MR0 can be enabled through MCR to reset the TC, stop both the TC and PC, and/or generate an interrupt every time MR0 matches TC.
MR1	R/W	0x1C	Match Register 1. The MR1 can be enabled through MCR to reset the TC, stop both the TC and PC, and/or generate an interrupt every time MR1 matches that TC.
-	-	0x38 0x20	Reserved
EMR	R/W	0x3C	External Match Register. The EMR contains control and status bits related to the external match pins m(0-1). EMR[7:4] is used to determine how EMR[1:0] and m(0-1) change when a match occurs.

## 4. Register description

**Table 311. Interrupt Register (IR) of the Watchdog Timer (address 0x1300 2400)**

Bit	Symbol	R/W	Reset Value	Description
0	intr_m0	R/W	0	Interrupt bit for a MR0 and TC mach. If an interrupt is being generated then the this bit will be one. Otherwise, the bit will be zero. Writing logic one will reset the interrupt. Writing a zero has no effect. Writing a one instead of a zero allows the user to write the contents of the Interrupt Register to itself thus providing a quick method of clearing.
1	intr_m1	R/W	0	Interrupt bit for a MR1 and TC mach. Operation is similar to intr_m0
31-2	-	-	-	Reserved

**Table 312. Timer Control Register (TCR) of the Watchdog Timer (address 0x1300 2404)**

Bit	Symbol	R/W	Reset Value	Description
0	Counter Enable	R/W	0	1- the Timer Counter is enabled for counting. 0- the counters are disabled.
1	Counter Reset	R/W	0	When one, the Timer Counter is synchronously reset on the next positive edge of WDOG_PCLK. The counters remain reset until TCR[1] is brought back to zero.
31-2	-	-	-	Reserved

**Table 313. TimerCounter Register (TC) of the Watchdog Timer (address 0x1300 2408)**

Bit	Symbol	R/W	Reset Value	Description
31-0	VAL	R	0	A read reflects the current value of the Watchdog Timer counter. A write loads a new value into the Timer counter. The TC is incremented every PR+1 cycles of WDOG_PCLK.

**Table 314. Prescale register (PR) of the Watchdog Timer (address 0x1300 240C)**

Bit	Symbol	R/W	Reset Value	Description
31-0	MAXVAL	R/W	0	It specifies the maximum value (MAXVAL) for the prescale Counter (PC). It allows the user to specify that the TC be incremented every PR+1 cycles of WDOG_PCLK.

**Table 315. Prescale counter Register (PC) of the Watchdog Timer (address 0x1300 2410)**

Bit	Symbol	R/W	Reset Value	Description
31-0	VAL	R	0	A read reflects the current value of the Watchdog Prescale counter. A write loads a new value into the Prescale counter. The PC is increment every WDOG_PCLK cycle when timer counter is enabled in TCR register.

**Table 316. Match Control Register (MCR, address 0x1300 2414)**

Bit	Symbol	R/W	Reset Value	Description
0	Interrupt on MR0	R/W	0	When one, an interrupt is generated through Event router when MR0 matches the value in the TC. When zero this interrupt feature is disabled.
1	Reset on MR0	R/W	0	When one, the TC will be synchronously reset if MR0 matches TC. When zero this feature is disabled.
2	Stop on MR0	R/W	0	When one, the TC and PC will stop counting and TCR[0] will be set to 0 if MR0 matches TC. When zero this feature is disabled.
3	Interrupt on MR1	R/W	0	When one, a system wide reset is generated through CGU when MR1 matches the value in the TC. When zero this interrupt feature is disabled.
4	Reset on MR1	R/W	0	When one, the TC will be synchronously reset if MR1 matches the TC. When zero this feature is disabled.
5	Stop on MR1	R/W	0	When one, the TC and PC will stop counting and TCR[0] will be set to 0 if MR1 matches TC. When zero this feature is disabled.
31-6	-	-	-	Reserved

**Table 317. Match Register (MR) of the Watchdog Timer (MR0, address 0x1300 2418; MR1, address 0x1300 241C)**

Bit	Symbol	R/W	Reset Value	Description
31-0	VAL	R/W	0	Holds the match value for the Timer Counter.

**Table 318. External Match Registers (EMR) of the Watchdog Timer (address 0x1300 243C)**

Bit	Symbol	R/W	Reset Value	Description
0	External Match 0	R/W	0	When match register 0 (MR0) equals the timer counter (TC) this output can either toggle, go to zero, go to one, or do nothing. EMR[4:5] controls the functionality of this output. Clearing M(0-1) can be done by writing directly to EMR.
1	External Match 1	R/W	0	When match register 0 (MR1) equals the timer counter (TC) this output can either toggle, go to zero, go to one, or do nothing. EMR[6:7] controls the functionality of this output. Clearing M(0-1) can be done by writing directly to EMR.
3-2	-	-	-	Reserved
5-4	External Match Control 0	R/W	0	Determines the functionality of External Match 0, table below shows the decode of these pins.
7-6	External Match Control 1	R/W	0	Determines the functionality of External Match 1, table below shows the decode of these pins.
31-8	-	-	-	Reserved

**Table 319. External Match Control**

CTRL_X[1]	CTRL_X[0]	Description
0	0	Do Nothing
0	1	Set LOW
1	0	Set HIGH
1	1	Toggle

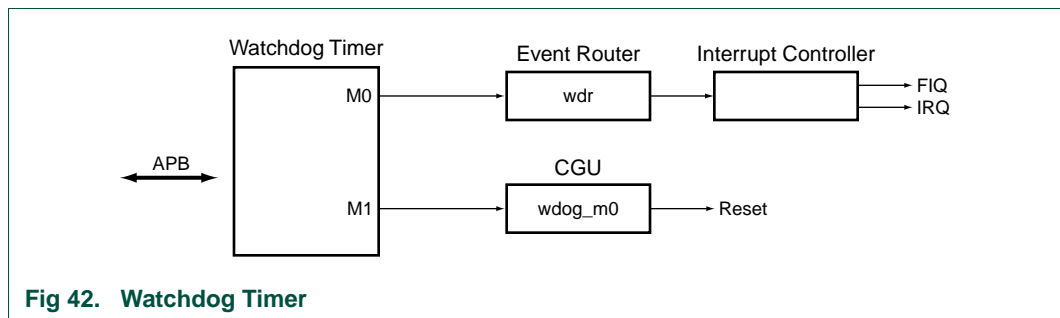

## 5. Functional description

The watchdog timer block is clocked by WDOG\_PCLK, which clocks a 32 bit counter. The timer counter is enabled through Timer control register (TCR). The module also has a prescale counter which can be used to further divide WDOG\_PCLK clock feeding the 32 bit Timer counter.

The counter block is configured for two Match Registers. Each Match Register is 32 bit wide, same as Timer Counter. Each Match Register can be configured through the Match Control Register to stop the Timer Counter, thus maintaining their value at the time of the match, restart the Timer Counter at zero, allow the counter to continue counting, and/or generate an interrupt when its contents match those of the TC. When MRx=TC, Reset on MRx is enabled through the MCR, and the TC is enabled through the TCR, then the Timer Counter is reset on rising edge of pclk. It should be noted that stop on match has higher priority than reset on match.

External Match register provides both control and status of the external match pins M(0-1). EMR[0:1] and M(0-1) can either toggle, go to zero, go to one, or maintain state when the contents of MRx is equal to the contents of TC. EMR[4:7] are used to specify the action taken by EMR[0:1] and M(0-1). Clearing M(0-1) can be done by writing directly to EMR. [Figure 14–42](#) shows how the Watchdog Timer is located in the LPC315x. Watch dog timer can be used in following different ways.

- As a watchdog The m1 output is used for generating an event to the CGU, which requests a reset.
- As a timer The m0 output is used for generating an event to the Event Router, which generates an interrupt to the Interrupt Controller. Note that the latency between the occurrence of an event at pin m0 and when the IRQ or FIQ will be asserted due this event, will be longer when the Timer Modules are used. Because the interrupts generated by the Timer Modules are directly connected to the Interrupt Controller, while the event of the Watchdog Timer goes via the Event Controller
- As watchdog and a timer The value of the MCR0 (Match Register 0) has to be a lower than the value of MCR1. Otherwise not desired resets will be generated by the CGU.

**Fig 42. Watchdog Timer**

Once the watchdog is enabled, it will monitor the programmed time-out period. The counter counts in modulo  $2^n$  fashion. An interrupt is generated if one of the Match Registers matches the contents of the Timer Counter indicating time-out. In normal operation the watchdog is triggered periodically, resetting the watchdog counter and ensuring that no reset is generated. In the event of a software or hardware failure preventing the CPU from triggering the watchdog, the time-out period will be exceeded and a reset requested from the CGU.

## 1. Introduction

---

The General Purpose Input/Output (GPIO) pins can be controlled through the register interface provided in the Input/Output Configuration module (IOCONFIG). Next to several dedicated GPIO pins, most digital IO pins can also be used as GPIO if not required for their normal, dedicated function.

### 1.1 Features

The IOCONFIG module supports the following features:

- Provides control for the digital pins that can double as GPIO (besides their normal function).
- Each controlled pin can be configured for 4 operational modes:
  - Normal operation (i.e. controlled by a function block - not GPIO)
  - Driven low (GPIO)
  - Driven high (GPIO)
  - High impedance/input
- The register interface provides 'set' and 'reset' access methods for choosing the operational mode.
- Conforms to APB interface specification.
- Programmable IO pads. All GPIO pads can be programmed in pull-up, pull-down, or repeater mode using the pad configuration registers in the system control block (see [Table 27–570 “SYSCREG\\_padname\\_PCTRL \(addresses 0x1300 28A4 to 0x1300 2A28\)”](#)).

## 2. General description

---

The IOCONFIG is comprised of a set of registers for individual control and visibility over a (relatively large) set of pads. By means of a set of pad multiplexers, individual pads can be switched to operate either in their normal mode, or in 'GPIO' mode. Such pads are referred to as functional pads, and are allocated to also service function blocks. In the normal mode of operation, the pad services the function block to which it is connected. In GPIO mode, a pad is fully controllable by way of dedicated bits in the mode registers, namely Mode1 and Mode0.

This block conforms to the ARM Peripheral Bus (APB) specification for ease of use with other APB peripherals.

**Remark:** Note that the pin multiplexing between different non-GPIO functions is controlled through the SYSCREG block, see [Section 27–4.8](#).

## 2.1 Interface description

### 2.1.1 Clock signals

Table 320. Clock Signals of the IOCONFIG module

Clock Name	Clock Name Acronym	I/O	Source/ Destination	Description
IOCONF_PCLK	pclk	I	CGU	APB bus clock; All registers are clocked on this clock.

### 2.1.2 Reset signals

The IOCONFIG module is reset by a synchronous APB bus reset.

For all functional pins controlled by the IOCONFIG registers, the reset signal sets all the MODE1 register bits to '0' and the MODE0 register bits to '1'. Hence, the subsystem modules themselves control their output at reset.

If the pins are GPIO only (GPIO0 to GPIO20), they are set as inputs at reset: Their mode register bits are set to MODE1 = 0 and MODE0 = 0 by the reset signal.

To ensure that GPIO0 to GPIO20 pins come up as inputs, pins TRST\_N and JTAGSEL must be low during power-on reset, see JTAG chapter for details.

## 3. Register overview

Table 321. Register overview: IOCONFIG, function block level (register base address 0x1300 3000)

Name	Access	Address offset	Description
EBI_MCI	-	0x000	Base address of the register set pertaining to the first set of 32 multiplexed pads.
EBI_I2STX_0	-	0x040	Base address of the register set pertaining to the second set of 32 of multiplexed pads.
CGU	-	0x080	Base address of the register set pertaining to the Clock Generation Unit function block.
I2SRX_0	-	0x0C0	Base address of the register set pertaining to I2SRX function block 0.
I2SRX_1	-	0x100	Base address of the register set pertaining to I2SRX function block 1.
I2STX_1	-	0x140	Base address of the register set pertaining to I2STX function block 1.
EBI	-	0x180	Base address of the register set pertaining to the External Bus Interface function block.
GPIO	-	0x1C0	Base address of the register set pertaining to the general purpose IO
I2C1	-	0x200	Base address of the register set pertaining to the I2C function block
SPI	-	0x240	Base address of the register set pertaining to the Serial Peripheral Interface function block.
NANDFLASH_CTRL		0x280	Base address of the register set pertaining to the NANDFLASH function block.
PWM		0x2C0	Base address of the register set pertaining to the Pulse Width Modulator function block.
UART		0x300	Base address of the register set pertaining to the Universal Asynchronous Receiver/Transmitter function block.

Each function block contains the registers in [Table 15–322](#). Address offsets are with respect to the address of each function block in [Table 15–321](#).

**Table 322. Register overview: Register level for each function block (register base addresses: 0x1300 3000 (EBI\_MCI), 0x1300 3040 (EBI\_I2STX\_0), 0x1300 3080 (CGU), 0x1300 30C0 (I2SRX\_0), 0x1300 3100 (I2SRX\_1), 0x1300 140 (I2STX\_1), 0x1300 3180 (EBI), 0x1300 31C0 (GPIO), 0x1300 3200 (I2C1), 0x1300 3240 (SPI), 0x1300 3280 (NANDFLASH\_CTRL), 0x1300 32C0 (PWM), 0x1300 3300 (UART))**

Name	R/W	Address offset	Write Operation Description	Read Operation Description
PINS	R	0x000	Disabled	Input pin state register. Reads the state of input pins.
-			Reserved	
-			Reserved	
-			Reserved	
MODE0	R/W	0x010	Load	
MODE0_SET	R/W	0x014	Set Bits	Read Mode 0.
MODE0_RESET	R/W	0x018	Reset Bits	
-		0x01C	Reserved	
MODE1	R/W	0x020	Load	
MODE1_SET	R/W	0x024	Set Bits	Read Mode 1.
MODE1_RESET	R/W	0x028	Reset Bits

## 5. Functional description

The IOCONFIG functionality is granulated into function blocks. Each function block addresses functional pads associated with one particular IP module. [Figure 15–43](#) shows the pad multiplexer logic (MUX) and depicts the behavior of the IOCONFIG module. The IOCONFIG controls the selection between 'GPIO' and 'normal' mode. This selection controls the propagation of output (out) and active-low output enable (oen) signals from reaching the functional pad.

**Fig 43. Pad multiplex logic connections**

When 'm1' is enabled, 'm0' controls the data being output. When 'm1' is disabled, 'm0' controls selection between GPIO and normal mode. The normal (non-GPIO) mode occurs when 'm0'=1 and 'm1'=0, hence 'out' and 'oen' from the subsystem are the driving signals for the pad.

A specific bit position within the Mode0 and Mode1 registers correspond to the m0, m1 signals of a specific pad respectively. Programming the corresponding bits as depicted in [Table 15–336](#) sets the operational state of a functional pad. Hence, changing modes of all functional pads requires at most two register access - i.e. to registers Mode0 and Mode1. As also depicted in [Table 15–336](#), the Mode0 and Mode1 registers are also addressable for set-bits and reset-bits access.

**Table 336. Functional Pad Mode Bits**

Mode 1 bit (m1)	Mode 0 bit (m0)	Operating mode of functional pad
0	0	Input - Output driver is disabled
0	1	Output is controlled by the device
1	0	Output is driven low
1	1	Output is driven high

Input values are not registered and always read directly from the pad's input driver through a pad multiplex logic regardless of the mode of the pad.

## 6. Programming guide

To program a particular subsystem module's I/O:

- Get the IOCONFIG module's base address
- Select the operating mode of a particular GPIO pin by programming specific bits of the Mode0, and Mode1 registers in accordance with [Table 15–336](#)
- Writing to a register is done by writing to an address location = (IOCONFIG Base Address + Function blocks' offset + Register's offset), as shown in [Table 15–321](#) and [Table 15–322](#) respectively.

Note: Through the APB, only 32-bit registers are addressed. Hence bitwise-shifting operators are used to fix the bit value in the exact bit position required in the mode registers.

## 1. Introduction

The four-channel, 10-bit successive approximation Analog-to-Digital converter (ADC) is able to convert one of its 4 analog input signals with a conversion rate of 400 kSamples/s for a 10-bit resolution. The resolution can be reduced down to 2 bit. The conversion rate increases in that case to 1500 kSamples/s.

**Remark:** On the LPC3152/54 ADC channel three is internally connected to the battery terminals on the analog die allowing to determine the battery voltage by software. Channel 3 must be configured appropriately to measure the battery level. Note that the battery charger contains its own internal comparator function to control the battery level without using the 10-bit ADC.

### 1.1 Features

This module has the following features:

- Programmable ADC resolution from 2 to 10 bits
- Single A/D and continuous A/D conversion scan mode
- Four analog input channels (one channel connected internally to the analog die), selected by an analog multiplexer
- Maximum conversion rate 400 kSamples/s for 10 bits resolution
- Individual result registers for each channel
- Power down mode performing minimal power dissipation
- Internal power management to switch off unused circuitry between conversion cycles
- No start-up cycles, no power down / power up recovery time

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock Signals

Table 337. Clock Signals of the ADC

Clock name	Acronym	I/O	Source/ Destination	Description
ADC_PCLK	pclk	I	CGU	APB Bus Clock. Clock from APB.
ADC_CLK	clk	I	CGU	Clock signal from CGU, frequency fclk = 31.25 kHz.

### 2.1.2 Pin connections

Table 338. ADC inputs

Name	Type	Description
ADC10B_GPA[2:0]	I	Analog inputs to be converted. The input voltage is between 0 V and 3.3 V.
ADC10B_VDDA33	I	ADC power
ADC10B_GNDA	I	ADC ground

### 2.1.3 Reset signals

The CGU provides two reset signals to the ADC block. PRESETN resets all registers and RESETN\_ADC10BITS provides a global reset to the ADC.

## 3. Register overview

Table 339. Register overview: ADC (register base address 0x1300 2000)

Name	Access	Address Offset	Description	Reset Value
ADC_R0_REG	R	0x00	Digital conversion data for analog input channel 0	NA
ADC_R1_REG	R	0x04	Digital conversion data for analog input channel 1	NA
ADC_R2_REG	R	0x08	Digital conversion data for analog input channel 2	NA
ADC_R3_REG	W	0x0C	Digital conversion data for analog input channel 3	NA
Reserved		0x10-0x1C		
ADC_CON_REG	R/W	0X20	Controls the ADC operation modes and gives status information	0x0000 0000
ADC_CSEL_REG	R/W	0X24	Defines which analog input channels are included and defines resolution in an A/D conversion	NA
ADC_INT_ENABLE_REG	R/W	0X28	Contains a variable to enable/disable the interrupt request generation	NA
ADC_INT_STATUS_REG	R	0x2C	Contains interrupt status variable that indicates the presence of interrupt condition	NA
ADC_INT_CLEAR_REG	W	0x30	Clears interrupt status variable in ADC_INT_STATUS register	NA
Reserved		0x34	-	NA

## 4. Register description

ADC contains 4 registers for the converted input results, a control register, a channel selection register, and three registers for interrupt control.

### 4.1 ADC data registers

The ADC data registers ADC\_Rx contain the output data, the output data is send to APB when CPU gives a read request. These registers store the result of an A/D conversion scan through 4 channels. Register ADC\_R0 is associated to channel 0 and ADC\_R1 to channel 1 and so on. The registers are read-only.

**Table 340. ADC\_Rx\_REG (ADC\_R0\_REG, address 0x1300 2000; ADC\_R1\_REG, address 0x1300 2004, ADC\_R2\_REG, address 0x1300 2008; ADC\_R3\_REG, address 0x1300 200C)**

Bit	Symbol	R/W	Reset Value	Description
9:0	ADC_Rx_DATA	R	NA	Digital conversion data with respect to analog input channel

## 4.2 ADC control register

This register controls the ADC operation modes and gives status information.

**Table 341. ADC\_CON\_REG (address 0x1300 2020)**

Bit	Symbol	R/W	Reset Value	Description
0	-	-	-	reserved
1	ADC_ENABLE	R/W	0	ADC enable: 0 = Non-operational mode 1: Operational mode
2	ADC_CSCAN	R/W	0	Continuous Scan: 0 = Single conversion 1 = Continuous conversion scan
3	ADC_START	R/W	0	Start command: 0 = No effect 1 = Start an A/D conversion scan
4	ADC_STATUS	R	0	ADC Status: 0 = no A/D conversion in progress 1 = A/D conversion scan is in progress Power down mode is not allowed when A/D conversion scan is in progress.
31:5	-	-	-	Reserved. Do not write ones to reserved bits.

## 4.3 ADC channel selection register

This register defines which analog input channels are included and defines resolution in an A/D conversion.

**Table 342. ADC\_CSEL\_RES\_REG (address 0x1300 2024)**

Bit	Symbol	R/W	Reset Value	Description
3:0	CSEL0	R/W	0	By setting the bit-resolution channel 0 is selected (2-10)
7:4	CSEL1	R/W	0	By setting the bit-resolution channel 1 is selected (2-10)

Table 342. ADC\_CSEL\_RES\_REG (address 0x1300 2024)

Bit	Symbol	R/W	Reset Value	Description
11:8	CSEL2	R/W	0	By setting the bit-resolution channel 2 is selected (2-10)
15:12	CSEL3	R/W	0	By setting the bit-resolution channel 3 is selected (2-10)
31:16	-	-	-	Reserved. Do not write ones to reserved bits.

#### 4.4 ADC interrupt enable register

This register contains a variable to enable/disable the interrupt request generation.

Table 343. ADC\_INT\_ENABLE\_REG (address 0x1300 2028)

Bit	Symbol	R/W	Reset Value	Description
0	ADC_INT_ENABLE	R/W	0	Interrupt enable: 0 = Disable 1 = Enable  An interrupt request is generated when the ADC_SCAN_INT_STATUS flag is set.
31:1	-	-	-	Reserved. Do not write ones to reserved bits.

#### 4.5 ADC interrupt status register

This register contains interrupt status variable that indicates the presence of interrupt condition. It is read-only.

Table 344. ADC\_INT\_STATUS\_REG (address 0x1300 202C)

Bit	Symbol	R/W	Reset Value	Description
0	ADC_INT_STATUS	R	0	Interrupt status: 0 = No interrupt pending 1 = Interrupt pending.
31:1	-	-	-	Reserved. Do not write ones to reserved bits.

#### 4.6 ADC interrupt clear register

A write action to this address location allows to clear interrupt status variable in the ADC\_INT\_STATUS register.

Table 345. ADC\_INT\_CLEAR\_REG (address 0x1300 2030)

Bit	Symbol	R/W	Reset Value	Description
0	ADC_INT_CLEAR	W	0	Interrupt clear: 0 = No effect 1 = clear ADC_SCAN_INT_STATUS variable.
31:1	-	-	-	Reserved. Do not write ones to reserved bits.

## 5. Functional description

### 5.1 A/D conversion control

The ADC performs analog input channel multiplexing, sampling and successive digital approximation of analog signals. The protocol sequence starts with the sampling of the selected analog input channels. This is followed by the 'approximation loop' in which the DAC voltage is stepwise approximated to the sampled input voltage. The number of loop cycles depends on whether 2,3,4,...,10 bit resolution is selected. The A/D conversion result becomes valid when the ADC\_INT\_STATUS bit is set (see [Table 16-344](#)), and the result is moved to the ADC\_Rx\_REG register of the corresponding channel(s).

### 5.2 ADC Resolution

The resolution within the AD conversion process is software programmable through the ADC\_CSEL\_RES\_REG ([Table 16-342](#)). The resolution can be adjust between 2 and 10 bits. The conversion rate is as follows:

$$\text{ConversionRate} = \frac{\text{ClockFrequency}}{(\text{Resolution} + 1)}$$

### 5.3 Multi-channel A/D conversion scan

Each analog input channel has a 10 bit result registers to store its A/D conversion result. By selecting a resolution from 2 to 10 bit through the ADC\_CSEL\_RES\_REG, a channel is included in the ADC scan. A channel is excluded from the scan if its resolution is set to 0. For example, it is possible to scan channel 0, channel1, and channel 3 without scanning channel 2. The A/D conversion scan process can be started by software.

There are two scan modes: Continuous Scan mode and Single Scan mode. In Continuous Scan mode, A/D conversion scans are carried out continuously: once one scan completed, the next one is started automatically. In Single Scan mode, only a single conversion scan is carried out, the next scan must be started explicitly by software.

### 5.4 Clocking

The clock for the ADC interface (ADC\_PCLK) is provided by the Clock Generation Unit (CGU).

The frequency of the ADC clock (ADC\_CLK) doesn't have to be very high because the number of samples can be low for measuring for example a battery voltage. Therefore the clock frequency ADC\_CLK that is offered by the Clock Generation Unit can be used (max is 4.5 MHz).

## 5.5 Interrupts

The ADC interface implements one interrupt, a scan interrupt which indicates the completion of an A/D conversion scan process and the validity of the data in the result registers.

## 6. Power optimization

To minimize the power consumption in the ADC, all the unused circuitry is switched off between conversions. During these inactive periods, the analog part is in Power-down mode, and the current from ADC10B\_VDDA33 is below 1  $\mu$ A. The current from VDDI is reduced to the clock buffers operation. The analog part of the ADC can be powered down via the ADC\_ENABLE bit in the ADC\_CON\_REG.

In addition, the analog part of the ADC can be set explicitly into power-down mode using a syscregister bit: SYSCREG\_ADC\_PD\_ADC10BITS (see [Table 27–538](#)).

## 7. Programming guide

Reset ADC Interface:

1. Write PRESETN: reset ADC\_CONTROLLER:

```
ADC_ENABLE = ADC_START = ADC_SELFREF = ADC_CSCAN = ADC_CSELO = ADC_CSEL1 =
ADC_INT_ENABLE = ADC_INT_STATUS = 0
```

Setup ADC Interface:

1. Read ADC Status => ADC\_INT\_STATUS = 0
2. Write ADC Interrupt Enable Register => ADC\_INT\_ENABLE = 1
3. Read ADC Interrupt Status Register => ADC\_INT\_STATUS = 0
4. Select reference voltage input (vrefp0) => ADC\_SELVREF = 1
5. Write Select Channel and Resolution Register => ADC\_CSELO until ADC\_CSEL3
6. Write ADC enable bit => ADC\_ENABLE = 1

Run Single Conversion Mode (ADC\_CSCAN = 0):

1. Write ADC Start Command => ADC\_START = 1
2. Write ADC Start Command => ADC\_START = 0
3. Wait for interrupt => ADC\_INT\_STATUS
4. Read ADC Interrupt Status Register => ADC\_INT\_STATUS = 1
5. Write ADC interrupt clear register => ADC\_INT\_CLEAR = 1
6. Read ADC Result Register for Channel 0 until Channel 4=> ADC\_R0.. ADC\_R4
7. Wait for ADC Interrupt Status Register => ADC\_INT\_STATUS = 0

Run Single Conversion Stops => Go back to Setup ADC Interface

Run Continuous Conversion Mode (ADC\_CSCAN = 1):

1. Write ADC Start Command => ADC\_START = 1

2. Write ADC Start Command => `ADC_START = 0`
3. Wait for interrupt => `ADC_INT_STATUS`
4. Read ADC Interrupt Status Register => `ADC_INT_STATUS = 1`
5. Write ADC interrupt clear register => `ADC_INT_CLEAR = 1`
6. Read ADC Result Register for Channel 0 until Channel 4=> `ADC_R0.. ADC_R4`
7. Wait for ADC Interrupt Status Register => `ADC_INT_STATUS = 0`
8. Run Continuous Conversion Start at point 3.
9. Stop Continuous Conversion => `ADC_CSCAN = 0`.

## 1. Introduction

---

The Event Router extends the interrupt capability of the system by offering a flexible and versatile way of generating interrupts. Combined with the wake-up functionality of the CGU, it also offers a way to wake-up the system from suspend mode (with all clocks deactivated).

### 1.1 Features

This module has the following features:

- Provides programmable routing of input events to multiple outputs for use as interrupts or wake-up signals.
- Input events can come from internal signals or from the pins that can be used as GPIO. Note that the GPIO pins can be used to trigger events when in normal, functional mode or in GPIO mode.
- Inputs can be used either directly or latched (edge detected) as an event source.
- The active level (polarity) of the input signal for triggering events is programmable.
- Direct events will disappear when the input becomes inactive.
- Latched events will remain active until they are explicitly cleared.
- Each input can be masked globally for all outputs at once.
- Each input can be masked for each output individually.
- Event detect status can be read for each output separately.
- Event detection is fully asynchronous (no active clock required).
- Module can be used to generate a system wake-up from suspend mode.

## 2. General description

---

The Event Router has four interrupt outputs that are connected to the interrupt controller and one wake-up output connected to the CGU as shown in [Figure 17-44](#). The output signals are activated when an event (for instance a rising edge) is detected on one of the input signals. The input signals of the Event Router are numerous and are connected to relevant internal (control) signals in the system or to external signals through pins of the LPC315x.

### 2.1.3 Interrupt request signals

Table 348. Interrupt Request Signals of Event Router

Name	Type	Description
INTERRUPT_0	O	interrupt output 0 connected to Interrupt controller as CASCADED_IRQ0
INTERRUPT_1	O	interrupt output 1 connected to Interrupt controller as CASCADED_IRQ1
INTERRUPT_2	O	interrupt output 2 connected to Interrupt controller as CASCADED_IRQ2
INTERRUPT_3	O	interrupt output 3 connected to Interrupt controller as CASCADED_IRQ3

### 2.1.4 Reset signals

The event router is reset by an APB bus reset (PNRES).

### 3. Register overview

All input event signals connected to the Event Router are grouped together in banks (k). If the number of input signals is larger than 32 a next bank is used (signal 33 becomes bit 0 of bank 1). The pending register shows the arrangement of the input event signal per bank. The bits of all other registers are arranged in the same way as the pending register but for reasons of simplicity the detailed bit information is left out

## 4. Register description

### 4.1 Pending Register pend[0] to pend[3]

The pending registers indicate when a masked input event is active. Reading a '1' indicates the input event is active, reading a '0' means no input event.

**Table 350. Pend [0] register (address 0x1300 0C00)**

Bit	Symbol	R/W	Reset Value	Description
31	EBI_D_6	R	0x0	input event from GPIO pin

3	timer1_intct1	R	0x0	input event from Timer 1
2	timer0_intct1	R	0x0	input event from Timer 0
1	GPIO20	R	0x0	input event from GPIO20
0	GPIO19	R	0x0	input event from GPIO19

## 4.2 Interrupt Clear Register int\_clr[0] to int\_clr[3]

These registers allow latched events to be cleared by writing a '1' to any bits corresponding to the interrupts to be cleared. The bits are arranged in the same way as the pending registers.

**Table 354.** int\_clr register(int\_clr0, address 0x1300 0C20; int\_clr1, address 0x1300 0C24  
int\_clr\_2, address 0x1300 0C28; int\_clr3, address 0x1300 0C2C)

Bit	Symbol	R/W	Reset Value	Description
31:0	int_clr	W	0x0	interrupt clear register, write any bit '1' to clear that interrupt latch (one bit per input)

### 4.3 Interrupt set register int\_set[0] to int\_set[3]

This register allows the user to generate an event through software. This register could be used for debugging the event router driver or for generating artificial events.

**Table 355.** int\_set register (int\_set0, address 0x1300 0C40; int\_set1, address 0x1300 0C44  
int\_set2, address 0x1300 0C48; int\_set3, address 0x1300 0C4C)

Bit	Symbol	R/W	Reset Value	Description
31:0	int_set	W	0x0	interrupt set register, write any bit '1' to set that interrupt latch (one bit per input)

### 4.4 Mask Register mask[0] to mask[3]

The mask register allows the user to enable or disable input events globally across all outputs. An event, which is enabled in this register, will cause activation of any outputs, which have also been programmed in the intoutMask register. An event, which is disabled, will not cause activation of any outputs. The bits are arranged in the same way as the pending register. For multi-thread applications separate addresses are also provided for clearing and setting of latch bits, removing the need for read-modify-write operations.

**Table 356.** mask register (mask0, address 0x1300 0C60; mask1, address 0x1300 0C64  
mask2, address 0x1300 0C68; mask3, address 0x1300 0C6C)

Bit	Symbol	R/W	Reset Value	Description
31:0	int_set	W	0xFFFFFFFF	global input event enable, one bit per input1 = enable, 0 = disable an input

### 4.5 Mask clear register mask\_clr[0] to mask\_clr[3]

These registers allow bits in the mask register to be clear by writing a '1' to any bits corresponding to the mask bits to be set. The bits are arranged in the same way as the pending register.

**Table 357.** mask register (mask\_clr0, address 0x1300 0C80; mask\_clr1, address 0x1300  
0C84; mask\_clr2, address 0x1300 0C88; mask\_clr3, address 0x1300 0C8C)

Bit	Symbol	R/W	Reset Value	Description
31:0	mask_clr	W	0xFFFFFFFF	event enable clear register, write any bit '1' to clear an input event enable (one bit per input)

### 4.6 Mask set register mask\_set[0] to mask\_set[3]

These registers allow bits in the mask register to be set by writing a '1' to any bits corresponding to the mask bits to be set. The bits are arranged in the same way as the pending register.

**Table 358. mask\_set register (mask\_set0, address 0x1300 0CA0; mask\_set1, address 0x1300 0C4A4; mask\_set2, address 0x1300 0CA8; mask\_set3, address 0x1300 0C8C)**

Bit	Symbol	R/W	Reset Value	Description
31:0	mask_set	W	0x0	event enable set register, write any bit '1' to set an input event enable bit (one bit per input)

#### 4.7 Activation polarity register apr[0] to apr[3]

The activation polarity register (APR) is used to configure which level is the active state for the event sources. A high bit indicates that the event is high sensitive, a low bit that it is low sensitive. The bits are arranged in the same way as the pending register.

**Table 359. apr[0] register (address 0x1300 0CC0)**

Bit	Symbol	R/W	Reset Value	Description
31:0	apr	R/W	0x1	activation polarity register (one bit per input) 1 = high sensitive, 0 = low sensitive

**Table 360. apr[1] register (address 0x1300 0CC4)**

Bit	Symbol	R/W	Reset Value	Description
31:0	apr	R/W	0x0	activation polarity register (one bit per input) 1 = high sensitive, 0 = low sensitive

**Table 361. apr[2] register (address 0x1300 0CC8)**

Bit	Symbol	R/W	Reset Value	Description
31:0	apr	R/W	0x1	activation polarity register (one bit per input) 1 = high sensitive, 0 = low sensitive

**Table 362. apr[3] register (address 0x1300 0CCC)**

Bit	Symbol	R/W	Reset Value	Description
31:30	-			Reserved
29:0	apr	R/W	0xFFFFFC	activation polarity register (one bit per input) 1 = high sensitive, 0 = low sensitive

#### 4.8 Activation type register atr[0] to atr[3]

The activation type register (ATR) is used to configure whether an event signal is used directly or if it is latched. If it is latched, the interrupt will persist after its event source has become inactive until it is cleared by an int\_clr write action. The event router includes an edge detection circuit, which prevents reassertion of an interrupt if the input remains at the active level after the latch is cleared. A high bit written to the ATR selects the latched event as the event source; a low bit uses the event directly. The bits are arranged in the same way as the pending register.

**Table 363. atr[0] register (address 0x1300 0CE0)**

Bit	Symbol	R/W	Reset Value	Description
31:0	atr	R/W	0x1	activation type register (one bit per input) 1 = latched(edge), 0 = direct

**Table 364. atr[1] register (address 0x1300 0CE4)**

Bit	Symbol	R/W	Reset Value	Description
31:0	atr	R/W	0x1	activation type register (one bit per input)1 = latched(edge), 0 = direct

**Table 365. atr[2] register (address 0x1300 0CE8)**

Bit	Symbol	R/W	Reset Value	Description
31:0	atr	R/W	0xFFFFFFC	activation type register (one bit per input)1 = latched(edge), 0 = direct

**Table 366. atr[3] register (address 0x1300 0CEC)**

Bit	Symbol	R/W	Reset Value	Description
31:30	-	R/W		Reserved
29:0	atr	R/W	0x77FFFFC	activation type register (one bit per input)1 = latched(edge), 0 = direct

#### 4.9 Raw status registers rsr[0] to rsr[3]

The Raw Status Register (RSR) shows unmasked events including latched events. A high bit read from the RSR indicates an event is (or has been) generated by the particular event source. A low bit read indicates the device is not generating an event. Level sensitive events are expected to be held and removed by the interrupt source. The bits are arranged in the same way as the pending register.

**Table 367. rsr registers (rsr0, address 0x1300 0D20; rsr1, address 0x1300 0D24; rsr2, address 0x1300 0D28; rsr3, address 0x1300 0D2C)**

Bit	Symbol	R/W	Reset Value	Description
31:0	rsr	R	0x0	raw status of input events or event latches in latched mode (one bit per input)

#### 4.10 Intout register

These registers show the current state of the event router interrupt outputs.

**Table 368. intout register (address 0x1300 0D40)**

Bit	Symbol	R/W	Reset Value	Description
31:5	-			reserved
4	cgu_wakeup	R	0x0	Current state of cgu_wakeup output
3	intout3	R	0x0	current state of interrupt output 3
2	intout2	R	0x0	current state of interrupt output 2
1	intout1	R	0x0	current state of interrupt output 1
0	intout0	R	0x0	current state of interrupt output 0

#### 4.11 Interrupt output pending register intoutPend[0:4][0:3]

With these registers the user can, for each individual interrupt output, enable/disable an input event to be routed to that output. The register/bit arrangement matches that of the pending register.

**Table 369.** intoutPend[m][n] register (m = 0 to 4, n = 0 to 3, intoutPend00, address 0x1300 1000; intoutPend01, address 0x1300 1004 to intoutPend43, address 0x1300 108C)

Bit	Symbol	R/W	Reset Value	Description
31:0	intoutPend	R	0x0	an array of status bits, one bit per input showing which events are pending for each interrupt output

#### 4.12 Interrupt output mask register intoutMask[0:4][0:3]

With these registers the user can, for each individual interrupt output, enable/disable an input event to be routed to that output. The bits are arranged in the same way as the pending register. For multi-thread applications separate addresses are also provided for clearing and setting of latch bits, removing the need for read-modify-write operations.

**Table 370.** intoutMask[m][n] (m = 0 to 4, n = 0 to 3, intoutMask00, address 0x1300 1400; intoutMask01, address 0x1300 1404 to intoutMask43, address 0x1300 148C)

Bit	Symbol	R/W	Reset Value	Description
31:0	intoutMask	R/W	0x0	enable bits for each interrupt output, connecting input events to that output. 1: input event is enabled 0: input event is disabled

#### 4.13 Interrupt output mask clear register intoutMaskClr[0:4][0:3]

Writing a bit to 1 in any of these registers clears the corresponding bit in the corresponding intoutMask register. The bits are arranged in the same way as the pending register.

**Table 371.** intoutMaskClr[m][n] register (m = 0 to 4, n = 0 to 3, intoutMaskClr00, address 0x1300 1400; intoutMaskClr01, address 0x1300 1404 to intoutMaskClr43, address 0x1300 148C)

Bit	Symbol	R/W	Reset Value	Description
31:0	intoutMaskClr	W	0x0	event enable clear register for each interrupt output, write any bit '1' to clear the corresponding bit in the corresponding output mask

#### 4.14 Interrupt output mask set register intoutMaskSet[0:4][0:3]

Writing a bit to 1 in any of these registers sets the corresponding bit in the corresponding intoutMask register. The bits are arranged in the same way as the pending register.

**Table 372.** intoutMaskSet[m][n] register (m = 0 to 4, n = 0 to 3, intoutMaskSet00, address 0x1300 1C00; intoutMaskSet01, address 0x1300 1404 to intoutMaskSet43, address 0x1300 1C8C)

Bit	Symbol	R/W	Reset Value	Description
31:0	intoutMaskSet	W	0x0	event enable set register for each interrupt output, write any bit '1' to clear the corresponding bit in the corresponding output mask

## 5. Functional description

### 5.1 Wake-up Behavior

All event sources, which are connected to the event inputs, can cause an wake-up trigger to the CGU module.

### 5.2 Architecture

The event router block is accessible through a APB interface. The number of interrupt outputs that can be generated is limited due to the maximum APB data size of 32 bit.

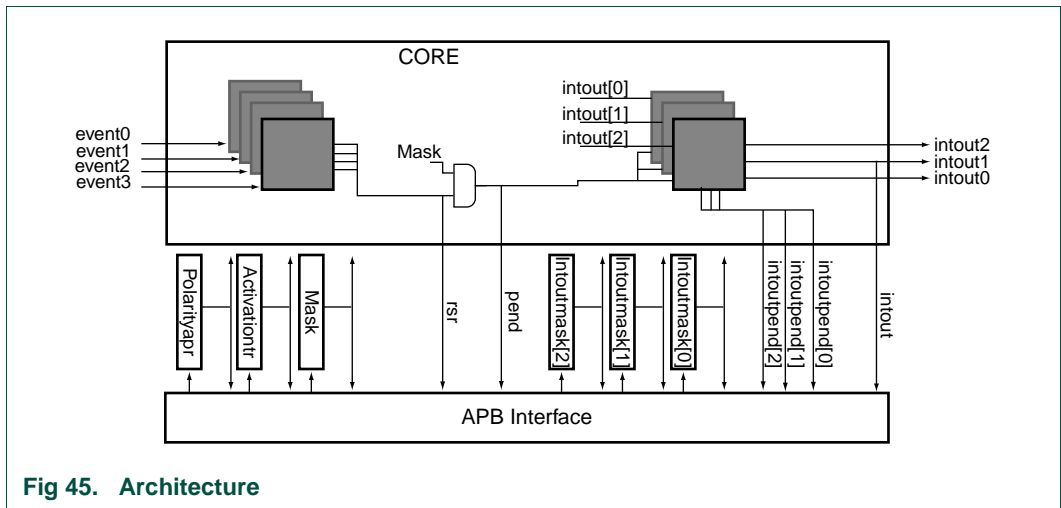

Fig 45. Architecture

Input events are processed in event slices, one for each event signal. Each of these slices generates one event signal and is visible in the rsr register. These events are then anded with enables from the mask register to give pending event status. All events are connected to an output slice for each output. In an output slice the signals from all inputs can be enabled or disabled to generate that output. There is a separate pending, mask, maskClr and maskSet register for each output slice.

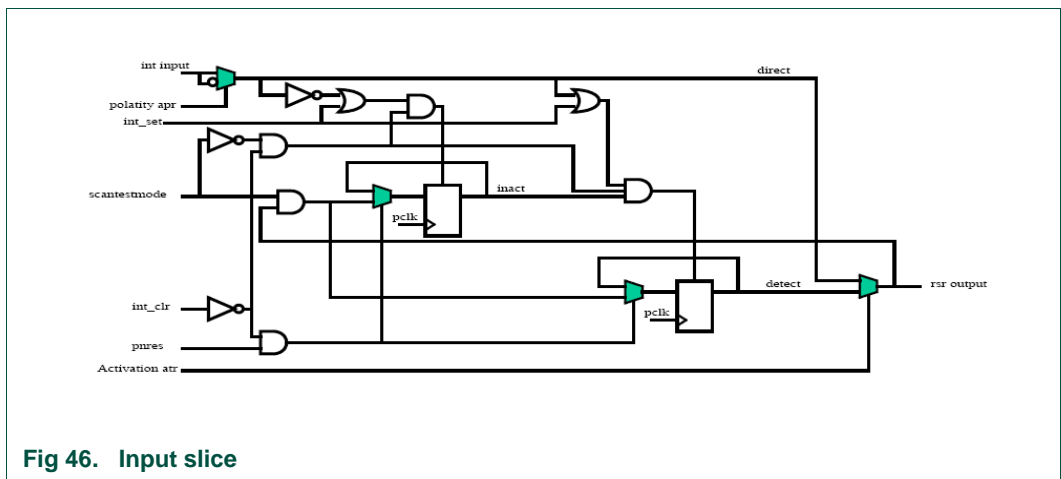

Fig 46. Input slice

An event slice is controlled through bits in the polarity, activation, intSet and intClr registers:

- The polarity setting conditionally inverts the interrupt input event
- The activation setting selects between latched or direct event
- The resulting interrupt event is visible through a read action on the raw status register
- Edge detection is performed by two registers with set functions. One detects the signal being inactive, the other detects the signal being active Latched
- These interrupt values are visible through read actions on the status registers
- A write '1' on the corresponding slice index in the intClr will clear the latched interrupt event synchronously.

For individual outputs, the results can be read on their specific intoutPend status register.

## 6. Power optimization

This module can be used in low power systems to request power-up or start of a clock on an external or internal event.

## 1. Introduction

---

The random number generator (RNG) generates true random numbers. Two independent ring oscillator clocks feed the RNG clock inputs. They provide a source clock, which varies from device to device, depending on the VLSI technology process and the device's own temperature. Because of this unstable clock source, the random numbers generated are highly unpredictable. Therefore, it is very unlikely that two random number generators, in two different systems, will generate the same random number sequence.

## 2. General description

---

### 2.1 Features

- True random number generator.
- Two internal generators, each fed by a dedicated ring oscillator clock.
- The ring oscillator clock sources are unstable, depending on both VLSI technology process spread and chip's temperature. The instability of the RNG clock sources is essential to guarantee true and highly unpredictable random numbers.
- Each internal generator combines the pseudo-random output of an LFSR (Linear Feedback Shift Register) and a MWCG (Multiply-with-Carry Generator).
- The random number register does not rely on any kind of reset.
- The generators are free running in order to increase the level of randomness and security.

### 2.2 Interface description

The RNG interface consists of a APB slave bus interface and two separate clock inputs. The independent clock inputs are directly fed to the RNG's internal random number generators

#### 2.2.1 Clock signals

Three clock signals are fed to the RNG.

Two clock sources, namely ANALOG\_CLK\_RNG[0], and ANALOG\_CLK\_RNG[1], are unstable. These two clocks are used to generate highly unpredictable random numbers. The input frequency of this clock sources should be in the range of 10 to 50 MHz.

The third clock, namely RNG\_PCLK, is used to clock the RNG APB bus interface logic and the RNG internal registers. The three clock domains are asynchronous to each other. The random numbers generated by the internal pseudo-random generators are sampled using the RNG\_PCLK to the RNG\_PCLK random number register. The frequency of the RNG\_PCLK is governed by the CGU and must be synchronous with the APB0 subsystem bus clock.

Table 373. Clock Signals of the RNG Module

Clock Name	I/O	Source/ Destination	Description
ANALOG_CLK_RNG[0]	I	CGU/RINGOSC0	The clock signal fed to the generator #0 of the RNG. The oscillator RINGOSC0 can be enabled via the SYSCREG block ( <a href="#">Table 27–537</a> ) register.
ANALOG_CLK_RNG[1]	I	CGU/RINGOSC1	The clock signal fed to the generator #1 of the RNG. The oscillator RINGOSC0 can be enabled via the SYSCREG block ( <a href="#">Table 27–537</a> ) register.
RNG_PCLK	I	CGU	RNG clock signal for the APB bus interface

### 2.2.2 Interrupt request signals

The RNG has no interrupt signals.

### 2.2.3 Reset signals

The CGU provides two reset signals to the RNG, the PNRES in the APB clock domain and a global asynchronous reset (HRESET).

## 3. Register overview

Table 374. Register overview: RNG (base register address: 0x1300 6000)

Name	R/W	Address Offset	Description
RANDOM_NUMBER	R	0x000	Random number
-	R	0x004	Reserved
-	R	0x008	Reserved
POWERDOWN	R/W	0xFF4	Power-down mode

## 4. Register description

Table 375. RANDOM\_NUMBER (address 0x1300 6000)

Bit	Symbol	R/W	Reset Value	Description
31:0	RANDOM_NUMBER	R	Random!	This register contains a random 32 bit number which is computed each time it is read

Table 376. POWERDOWN (address 0x1300 6FF4)

Bit	Symbol	R/W	Reset Value	Description
31:3	-	-	-	Reserved

Table 376. POWERDOWN (address 0x1300 6FF4) ...continued

Bit	Symbol	R/W	Reset Value	Description
2	Power down	R/W	0x0	When set all accesses to standard registers are blocked
1	Force soft-reset	R/W	0x0	When used in combination with soft-reset it forces an RNG reset immediately
0	Soft-reset	R/W	0x0	Request a software RNG reset, to be executed when the APB slave interface is deselected, and or pending APB register read/write operations are completed

## 5. Functional description

Each of the two internal generators combines the pseudo-random output of an LFSR (Linear Feedback Shift Register) and a MWCG (Multiply-with-Carry Generator). These generators are free running as long as the ring oscillator clock is available on the ANALOG\_CLK\_RNG input port.

The final random number is created by xor'ing the output of both internal generators. Each generator runs using a different input frequency. This guarantees that the random number generated will have good statistical random properties.

Each time the RANDOM\_NUMBER is queried, the final xor'ed value is sampled and stored on the internal APB register. For a correct sampling process both the RNG\_CLK and the ANALOG\_CLK\_RNG clocks must be running.

Once the Ring Oscillator clocks are enabled via the SYSCREG ([Table 27–537](#)), and the RNG\_PCLK clock is enabled, the block provides a random number every time the RNG random register is read via the APB bus.

The block never allows the same number to be read more than once. To prevent two consecutive readings being performed via the APB bus, the RNG will complete the second APB bus read operation only when a new random number is available. The latency of producing random numbers depends on the frequency of the ring oscillator clocks.

A random number is generated after 5 clock cycles of the slower of the two clocks provided in the ANALOG\_CLK\_RNG input ports. During this time the RNG retains the control on the APB bus.

## 6. Power optimization

To reduce power, the ring oscillators can be switched off, via the system register, when no random number is needed. The RNG can be switched off either by setting the POWERDOWN register in power down mode, or by disabling the RNG\_PCLK clock in the CGU.

## 7. Programming guide

---

Always make sure that when reading the `RANDOM_NUMBER` register, the RNG must be active, and the oscillators must be enabled.

### 7.1 Enabling the RNG

- Set the `POWERDOWN` bit to '0'.
- Enable the `RNG_PCLK` clock via the CGU.
- Enable both Ring Oscillator clocks via the system configuration register [Table 27–537](#).

### 7.2 Reading a random number from the RNG

- Read register `RANDOM_NUMBER`.

### 7.3 Disable the RNG

- Switch off the RNG clock via the CGU.
- Switch off the Ring Oscillators' clocks via the system register [Table 27–537](#).

## 1. Introduction

The OTP is a secure one-time programmable memory device used for storing non-volatile information like serial number, security bits, etc. It consists of a polyfuse array, embedded data registers and control registers. One of the main features of the OTP is storing a security key and a unique ID needed to support DRM.

### 1.1 Features

- 512-bit one-time programmable memory (for details see [Figure 19–49](#)):
  - 128 bits are used for a unique ID, which is pre-programmed in the wafer fab.
  - 128 bits are used for an AES key for secure boot-code execution (LPC3154 only); the customer should program these bits with the key used to encrypt the boot image. The boot ROM then uses this key to decrypt the boot image. On the LPC3152, these bits are available for customer-defined data.
  - 192 bits are available for customer-defined data, except for 8 bits which are reserved for NXP use.
  - 64 bits are used for JTAG security setting, bandgap adjustment value for the analog die, AES validation keys (LPC3154 only), and chip ID.
- Programmable at the customer production line.
- Random read access via sixteen 32-bit registers.
- Flexible read protection mechanism to hide security related data.
- Flexible write protection mechanism.

## 2. General description

### 2.1 Block diagram

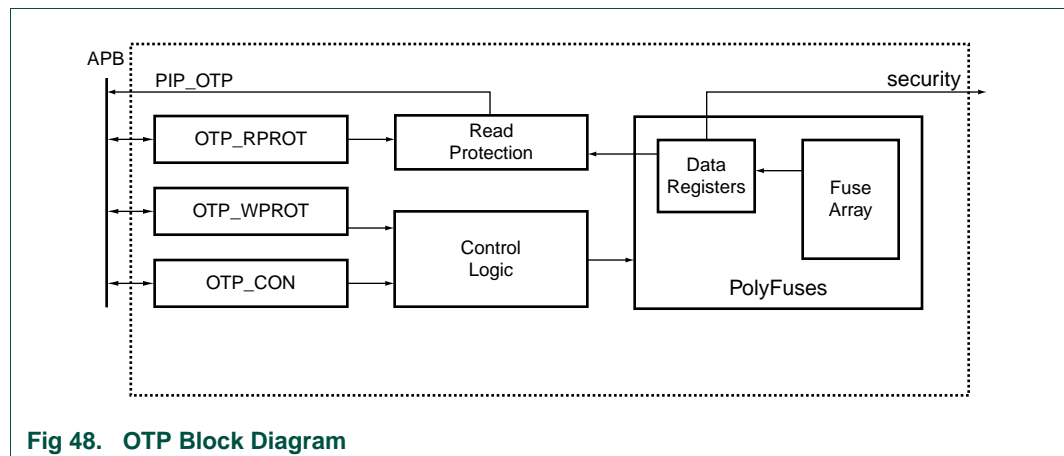

Fig 48. OTP Block Diagram

## 2.2 Electrical specification

The timing and electrical specifications of the OTP are defined by the characteristics of the used polyfuses. One should take care that lower than normal clock speeds are needed to read and write to the OTP:

**Table 377. Electrical specification**

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
$V_{DD(Core)}$	core supply voltage		1.00	1.20	1.30	V
$V_{prog(pf)}$	polyfuse programming voltage	write; to be applied after $V_{DD(Core)}$	2.70		3.60	V
		read	1.10		1.3	V
$T_j$	junction temperature		-40	+25	+125	°C
$I_{DD(idle)}$	Idle mode supply current			200		nA

**Remark:** A requirement for the write mode is that the VPP for writing should be applied after the application of the VDD. The sequence for entering the write mode is, to first start up in read mode and then switch to write mode.

**Remark:** For reading, it is advisable to program OTP\_PCLK\_CLK below 30 MHz. For writing to the OTP, the frequency should be between 100 kHz and 500 kHz.

**Remark:** Take extra care when writing as wrong timing can destroy the chip.

## 2.3 Interface description

The OTP only interfaces to the APB0. From here the control registers and data registers can be accessed. The only dedicated output signals are used for security.

### 2.3.1 Clock signals

**Table 378. Clock Signals of the OTP Module**

Clock Name	I/O	Source/Destination	Description
OTP_PCLK	I	CGU	APB Bus Clock

### 2.3.2 Pin connections

**Table 379. Signals to the IC pins for the OTP Module**

Name	Type	Description
VPP	Power	Dedicated power pin for reading and writing to the OTP. Different voltages are used for both operations

### 2.3.3 Reset signals

The OTP block is reset by an APB bus reset during POR reset and also when RSTIN\_N is asserted to the LPC315x digital die.

### 3. Register overview

**Table 380. Register overview: OTP module (base address 0x1300 5000)**

Name	R/W	Address offset	Description
<b>Control registers</b>			
OTP_con	R/W	0x000	Control Register
OTP_rprot	R/W	0x004	Read-protect Register
OTP_wprot	R/W	0x008	Write-protect Register
<b>Data registers</b>			
OTP_data_0	R	0x00C	Fuse-output data register
OTP_data_1	R	0x010	Fuse-output data register
OTP_data_2	R	0x014	Fuse-output data register
OTP_data_3	R	0x018	Fuse-output data register
OTP_data_4	R	0x01C	Fuse-output data register
OTP_data_5	R	0x020	Fuse-output data register
OTP_data_6	R	0x024	Fuse-output data register
OTP_data_7	R	0x028	Fuse-output data register
OTP_data_8	R	0x02C	Fuse-output data register
OTP_data_9	R	0x030	Fuse-output data register
OTP_data_10	R	0x034	Fuse-output data register
OTP_data_11	R	0x038	Fuse-output data register
OTP_data_12	R	0x03C	Fuse-output data register
OTP_data_13	R	0x040	Fuse-output data register
OTP_data_14	R	0x044	Fuse-output data register
OTP_data_15	R	0x048	Fuse-output data register

### 4. Register description

#### 4.1 Control registers

OTP contains three control registers.

After reset, when lock = 0, the register can be written to '1's or '0's. Once the lock bit has been set to '1', the register is locked and the bits in the register can be set, but not cleared. This means that in a locked register, you can only disable writing or reading, enabling (set bit to '0') is not possible. Very similar operation for OTP\_rprot register. The only difference between OTP\_rprot and OTP\_wprot is the reset value. After reset, OTP\_rprot.prot = 0x0000, whereas OTP\_wprot.prot = 0xFFFF. After locks are set on read and write protect, the only way to reset the protect settings and the locks is with a reset.

**Table 381. OTP\_con register (address 0x1300 5000)**

Bit	Symbol	R/W	Reset Value	Description
8:0	ADRS	R/W	0x0	Address bits for writing and copying fuse data
15:7	-	-	-	reserved

**Table 381. OTP\_con register (address 0x1300 5000)**

Bit	Symbol	R/W	Reset Value	Description
17:16	MODE	R/W	0x0	Selects: Idle, Copy and Write mode
30:18	-	-	-	reserved
31	JTAG_EN	R/W	0	This sticky bit can be set in application to enable the ARM_JTAG clock

**Table 382. OTP\_rprot register (address 0x1300 5004)**

Bit	Symbol	R/W	Reset Value	Description
15:0	PROT	R/W	0x0	Indicates which data registers are read-protected
30:16	-	-	-	reserved
31	LOCK	R/W	0	If selected all register values are 'sticky'

**Table 383. OTP\_wprot register (address 0x1300 5008)**

Bit	Symbol	R/W	Reset Value	Description
15:0	PROT	R/W	0x0	Indicates which data registers are write-protected
30:16	-	-	-	reserved
31	LOCK	R/W	0	If selected all register values are 'sticky'

## 4.2 Data registers

The bits in the data registers are described in the OTP fuse map and are different for LPC3152 and LPC3154, see [Figure 19-49](#).

**Table 384. OTP\_data0 to OTP\_data15 registers (addresses 0x1300 500C to 0x1300 5048)**

Register	Bit	Symbol	R/W	Reset Value	Description
OTP_data_0	31:0	DATA_0	R	Undefined	Fuse output Q[31..0]
OTP_data_1	31:0	DATA_1	R	Undefined	Fuse output Q[63..32]
OTP_data_2	31:0	DATA_2	R	Undefined	Fuse output Q[95..64]
OTP_data_3	31:0	DATA_3	R	Undefined	Fuse output Q[127..96]
OTP_data_4	31:0	DATA_4	R	Undefined	Fuse output Q[159..128]
OTP_data_5	31:0	DATA_5	R	Undefined	Fuse output Q[191..160]
OTP_data_6	31:0	DATA_6	R	Undefined	Fuse output Q[223..192]
OTP_data_7	31:0	DATA_7	R	Undefined	Fuse output Q[255..224]

OTP_data_13	31:0	DATA_13	R	Undefined	Fuse output Q[447..416]
OTP_data_14	31:0	DATA_14	R	Undefined	Fuse output Q[479..448]
OTP_data_15	31:0	DATA_15	R	Undefined	Fuse output Q[511..480]

## 5. Functional description

---

Access to the OTP is only possible via APB bus during application. In test-mode the fuse block itself can be accessed through JTAG. By programming the control registers, different actions can be performed on the fuse block (Read/Copy/Write/Protection settings):

- **Writing / Programming:** OTP programming is done via the OTP\_con register. Only a single bit can be programmed (written with 1) at a time. Programming of bits in OTP\_data\_0 to OTP\_data1\_5 can be disabled, by setting the appropriate bit in the OTP\_wprot register. Furthermore write protection can be made permanent by setting the OTP\_wprot.lock bit.
- **Copying:** After reset OTP\_data\_0 to OTP\_data\_15 contain invalid data. The boot code copies the data from the fuse array to the OTP\_data registers by writing the appropriate command sequence into OTP\_con.
- **Reading:** Reading the OTP is possible via sixteen 32-bit latches OTP\_data\_0 to OTP\_data\_15. Word, halfword and byte APB accesses are allowed. Read access from OTP\_data\_0 to OTP\_data\_15 can be individually disabled, by setting the appropriate bit in the OTP\_rprot register. Furthermore read protection can be made permanent by setting the OTP\_rprot.lock bit.
- **Write protection:** is handled with the OTP\_wprot register. It is combined with the fuses address to generate a signal called wprot\_on used inside the control block to enable a fuse write operation or not (basically wprot\_on= OTP\_wprot.prot[OTP\_con.addr[8:5]).

The reset pin of the fusebox is not connected to the APB reset pin pnres for security reasons. Instead, this pin was tied to '0', thus OTP\_DATA latches are not reset anymore and may have a significant value on their outputs after a reset. Only after the boot code has performed a copy from the fuse array to the latches the data will be defined. Once a latch has a significant value, a reset will not change this value. Control registers (CON, RPROT and WPROT) are reset by the APB pnres.

## 6. Power optimization

---

Power saving for the OTP is not needed. The module is not very large and will not be very power consuming. The fuses will be accessed only at startup when all data is copied to the data registers.

## 7. Programming guide

---

For programming it is important to define two separate use cases. The normal 'application use case', and an exceptional 'production line use case' for programming and testing the OTP at the production line.

### 7.1 Production line use case

At the NXP production line the OTP will be tested and programmed using JTAG. In test mode, the fuse block itself will be accessed directly. During programming the VPP will need a higher voltage than in the application use case. Written data is checked afterwards by reading out the fuses (using a low voltage on VPP)

The customer will also program the OTP only at the production line, here DFU programming will be used.

An image for programming customer-selected bits can be loaded into the device via USB.

## 7.2 Application use case

Initially it is important to make sure that the data\_15 register is updated early during the initialization (by boot-code) this will set the security level. Four levels of security are implemented in the design:

- Level 0: nothing is protected.
- Level 1: password protected. In this level, JTAG can be enabled by software after password sequence (depends on customer application) by setting the sticky bit 'JTAG\_EN' in OTP\_con register.
- Level 2: In this level, JTAG access can be enabled using special test equipment. Used by NXP for Returned Material Analysis only.
- Level 3: JTAG is completely disabled and hence the chip is virtually locked.

The customer can program the security level of the chip. For level 1, fuse-bit 509 should be set. For level 2, fuse-bits 509 and 510 are set. For level 3, fuse-bits 509, 510 and 511 are programmed. A special case will be for the customer to disable writing to the fuses, but since in application a low voltage (for reading) will be connected to the VPP, writing will not be possible anyway.

During normal application, the fuses will already have been programmed on the production line. So three options remain: copying the fuse data into the data registers, reading this data, and setting the read protection. The boot code will copy the fuse data into the data registers because this is needed for security and DRM. After this, the data can be read from the data registers via the APB0 bus (according to the read protection settings).

Modes are selected by programming the OTP\_CON register:

- 00 and 11 select Idle mode. Previously copied data to datareg\_15 can be accessed (so this mode is used when reading).
- 01 corresponds to copy mode, where the fuse data is collected (at startup).
- 10 corresponds to write mode (at production line).

### 7.3 OTP fuse map

**NXP programmed fuses**

- 128 bit Unique ID blown during wafer test
- Reserved for NXP use.
- Bandgap adjustment value valid for LPC315x parts. This value is calculated based on the analog die process parameters.
- This field stores the chip ID to identify the chip from software. LPC3152=0x0D, LPC3154=0x07.

**Customer programmed fuses**

- Customer should program 128 bit AES key used to encrypt the boot image in these fuses. Boot ROM uses this key to decrypt the boot image. For LPC3152 this field is not used hence customer can store any data. Customer can use these fuses to store any data of their choice.
- Customer should program the USB product ID (PID) to be used by boot ROM during USB-DFU class enumeration process.
- Customer should program the USB vendor ID (VID) to be used by boot ROM during USB-DFU class enumeration process.
- Customer can program these fuses to specify various level of JTAG security.
- 504 Customer should program this fuse to indicate AES key programmed in fuses 128:255 is valid.
- 503 Customer should program this fuse to indicate PID & VID key programmed in fuses 448:479 is valid.
- 502 Customer should program this fuse to indicate boot ROM not to switch to USB-DFU mode when valid boot image is not found in SPI, NAND & SD/MMC memories.

Fig 49. OTP fuse map

## 1. Introduction

---

The Serial Peripheral Interface (SPI) module is used for synchronous serial data communication with other devices that support the SPI/SSI protocol.

Examples of the devices that this SPI module can communicate with are memories, cameras, and WiFi-g. The SPI/SSI-bus is a 5-wire interface and is suitable for low, medium, and high data rate transfers.

### 1.1 Features

- Motorola SPI frame format with a word size of 8/16 bits
- Texas Instruments SSI frame format with a word size of 4 to 16 bits
- Serial clock rate master mode maximum 45 MHz
- Serial clock rate slave mode maximum 25 MHz
- Support for single data access DMA
- Full-duplex operation
- Maskable interrupts
- Multiple slaves support (maximum of 3 slaves)

## 2. General description

---

The SPI is a serial bus standard that was established by Motorola and is supported in silicon products from various manufacturers. In operation, there is a clock, a 'data in', a 'data out,' and a 'chip select' for each integrated circuit that is to be controlled. Most serial digital devices can be controlled with this combination of signals.

Devices communicate using a master/slave relationship, in which the master generates the clock and selects a slave device. The data may be transferred in either, or both directions simultaneously. In fact, as far as SPI is concerned, data is always transferred in both directions. It is up to the master and slave devices to know whether a received byte is meaningful or not.

The SSI (Synchronous Serial Interface) is similar to the SPI protocol. It makes use of the same pins. However in this protocol the data is only clocked out on the falling edge and clocked in on the rising edge of the master. In the SPI protocol this may be swapped. The SSI protocol was established by Texas Instruments.

## 2.1 Interface description

### 2.1.1 Clock signals

Table 385. SPI Module Clock Signals

Clock Name	I/O	Source/ Destination	Description
SPI_CLK	I	CGU	Main clock of the module. Most of the logic in this module runs on this clock. Its frequency depends on the required speed for the external SPI interface. The maximum frequency is 90 MHz.
SPI_CLK_GATED	I	CGU	Gated clock of main clock, SPI_CLK. The logic, which generates the serial clock, runs on this clock. To enable the clock gating for this clock its CGU register has to be set. The maximum frequency is 90 MHz.
SPI_PCLK	I	CGU	APB bus clock. The registers, the DMA request circuitry and the interrupt request circuitry run on this clock. Its frequency can be chosen independent of the other clocks, except from the SPI_PCLK_GATED, in this module.
SPI_PCLK_GATED	I	CGU	Gated clock of SPI_PCLK. The logic, like registers, runs on this clock. To enable the clock gating for this clock its CGU register has to be set.
SPI_SCK_OUT	O	Pin	Serial SPI clock out for master mode. This clock is in master mode derived from SPI_CLK(_GATED) with a programmable divider ratio (oversampling ratio). In master mode the frequencies of SPI_SCK and SPI_CLK should satisfy $f_{SPI\_CLK} \geq 2 \times f_{SPI\_SCK}$ .
SPI_SCK_IN	I	Pin	Serial SPI clock in for slave mode. In slave mode the frequencies of SPI_SCK_IN and SPI_CLK should satisfy $f_{SPI\_CLK} \geq 4 \times f_{SPI\_SCK}$ .

The clock domain between the APB clock and SPI\_CLK is asynchronous, allowing the APB clock frequency to be independent from the SPI clock frequency.

### 2.1.2 Bus interface

The SPI module has a APB bus connection that is connected to APB Bus 2. Through this bus interface the registers of the module are accessed.

### 2.1.3 Pin connections

Table 386. SPI pin connections

Pin name	Type (func)	Reset Value	Description
SPI_MOSI	I/O	-	Data output for master and data input for slave. This pin is fed by SPI_RXD port and the output of this pin goes to the SPI_TXD port.
SPI_MISO	I/O	-	Data input for master and data output for slave. This pin is fed by SPI_RXD port and the output of this pin goes to the SPI_TXD port.
SPI_SCK	I/O	0	Serial clock out (master mode, SPI_SCK_OUT port) and in (slave mode, SPI_SCK_IN).
SPI_CS_IN	I	-	Chip select in, used in slave mode.

Table 386. SPI pin connections

Pin name	Type (func)	Reset Value	Description
SPI_CS_OUT0	O	0	Chip select out for slave 0, used in master mode.
SPI_CS_OUT1	O	0	Chip select out for slave 1, used in master mode. This pin is multiplexed to mUART_CTS_N.
SPI_CS_OUT2	O	0	Chip select out for slave 2, used in master mode. This pin is multiplexed to mUART_RTS_N.

### 2.1.4 Interrupt request signals

The SPI module has 4 interrupt request signals to the interrupt controller and a common interrupt request signal that is asserted when any of the individual SPI interrupts are asserted. The Rx time-out interrupt, if enabled in the interrupt register (see [Table 20–403](#)), is asserted only as the SPI common interrupt request and does not have a separate interrupt connection to the VIC.

Table 387. Interrupt request signals

Name	Type	Description
SPI_INT	O	SPI common interrupt request
SPI_SMS_INT	O	SMS ready interrupt request
SPI_TX_INT	O	Tx threshold interrupt request
SPI_RX_INT	O	Rx threshold interrupt request
SPI_OV_INT	O	Rx FIFO overrun interrupt request

### 2.1.5 Reset signals

The CGU provides two synchronous reset signals to the SPI block: SPI\_RST\_N, which resets the logic in the SPI\_CLK domain and it is low active, and APB\_RST\_N, which resets the logic in the SPI\_PCLK domain of the module and is low active.

These resets should be used at the same time to reset the module.

### 2.1.6 DMA transfer signals

Table 388. SDMA Signals

Name	Type	Description
DMA_RX_SREQ	O	Receive DMA single transfer request.
DMA_TX_SREQ	O	Transmit DMA single transfer request.

## 3. Register overview

Table 389. Register overview (register base dress 0x1500 2000)

Name	R/W	Address Offset	Description
<b>SPI configuration registers</b>			
SPI_CONFIG	R/W	0x000	Configuration register
SLAVE_ENABLE	R/W	0x004	Slave enable register
TX_FIFO_FLUSH	W	0x008	Transmit FIFO flush register
FIFO_DATA	R/W	0x00C	FIFO data register

Table 389. Register overview (register base dress 0x1500 2000)

Name	R/W	Address Offset	Description
NHP_POP	W	0x010	NHP pop register
NHP_MODE	R/W	0x014	NHP mode selection register
DMA_SETTINGS	R/W	0x018	DMA settings register
STATUS	R	0x01C	Status register
HW_INFO	R	0x020	Hardware information register
<b>SPI slave registers</b>			
SLV0_SETTINGS1	R/W	0x024	Slave settings register 1 (for slave 0)
SLV0_SETTINGS2	R/W	0x028	Slave settings register 2 (for slave 0)
SLV1_SETTINGS1	R/W	0x02C	Slave settings register 1 (for slave 1)
SLV1_SETTINGS2	R/W	0x030	Slave settings register 2 (for slave 1)
SLV2_SETTINGS1	R/W	0x034	Slave settings register 1 (for slave 2)
SLV2_SETTINGS2	R/W	0x038	Slave settings register 2 (for slave 2)
-		0x03C-0xFD0	Reserved
<b>SPI interrupt registers</b>			
INT_THRESHOLD	R/W	0xFD4	Tx/Rx threshold interrupt levels
INT_CLR_ENABLE	W	0xFD8	INT_ENABLE bits clear register
INT_SET_ENABLE	W	0xFDC	INT_ENABLE bits set register
INT_STATUS	R	0xFE0	Interrupt status register
INT_ENABLE	R	0xFE4	Interrupt enable register
INT_CLR_STATUS	W	0xFE8	INT_STATUS bits clear register
INT_SET_STATUS	W	0xFEC	INT_STATUS bits set register
-	-	0xFF0-0xFF8	Reserved

## 4. Register description

### 4.1 SPI configuration registers

Table 390. SPI Configuration register (SPI\_CONFIG, address 0x1500 2000)

Bit	Symbol	Access	Reset Value	Description
31:16	inter_slave_dly	R/W	0x1	The minimum delay between two transfers to different slaves on the serial interface (measured in clock cycles of the SPI_CLK). The minimum value is 1.
15:8	-	-	0	Reserved
7	update_enable	W		Update enable bit. It must be set by software when the SLAVE_ENABLE register had been programmed. It will be automatically cleared when the new value is in use. 0: the current value in the SLAVE_ENABLE register is being used for transmission. A new value may be programmed. As soon as update enable is cleared again the new value is used for transmission. 1: the newly programmed value in the SLAVE_ENABLE register is not used for transmission yet. As soon as the value will be used for transmission this bit will clear automatically. In SMS mode the newly programmed value will be used when the pending SMS transfer finishes. In normal transmission mode newly programmed value will be used right away (after some clock domain synchronization delay)
6	Software_reset	R/W	0	Software reset bit. Writing '1' to this bit will reset the block completely. This bit is self clearing.
5	-	-	-	Reserved
4	Slave_disable	R/W	0	Slave output disable is only relevant in slave mode. When multiple slaves are connected to a single chip select signal for broadcasting of a message by a master, only one slave may drive data on its transmit data line (since all transmit data lines of the slaves are tied together to the single master). 0: slave can drive its transmit data output 1: slave must not drive its transmit data output.
3	Transmit_mode	R/W	0	Transmit mode 0: normal mode 1: sequential multi-slave mode. For slave mode this bit must be 0.

**Table 390. SPI Configuration register (SPI\_CONFIG, address 0x1500 2000) ...continued**

Bit	Symbol	Access	Reset Value	Description
2	Loopback_mode	R/W	0	<p>Loopback mode bit</p> <p>0: normal serial interface operation</p> <p>1: transmit data is internally looped-back and is received.</p> <p>Note: when the RX FIFO width is smaller than the TX FIFO width, then the most significant bit of the transmitted data is lost in loopback mode.</p>
1	Ms_mode	R/W	0	<p>master/slave mode bit0: master mode1: slave mode.</p>
0	Spi_enable	R/W	0	<p>SPI enable bit. When this bit is set the module is enabled.</p> <p>Slave mode: If the module is not enabled, it will not accept data from a master or send data to a master.</p> <p>Master mode: If there is data present in the transmit FIFO the module starts transmitting. Before setting this bit, at least one slave should be selected in the SLAVE_ENABLE register. In sequential multi-slave mode this bit is self-clearing.</p> <p>0: disables SPI</p> <p>1: enables SPI.</p>

**Table 391. Slave Enable register (SLAVE\_ENABLE, address 0x1500 2004)**

Bit	Symbol	Access	Reset Value	Description
31:6	-	-	0	Reserved
5:0	slave_enable	R/W	0x0	<p>Slave enable bits (bits [1:0] -&gt; slave 1, bits [3:2] -&gt; slave 2, etc.) Per slave 2 bits are used. There are three possible values:</p> <p>00: the corresponding slave is disabled</p> <p>01: the corresponding slave is enabled</p> <p>11: the corresponding slave is suspended (10: not supported).</p> <p>Note: in normal transmission mode only, one slave may be enabled and the others should be disabled.</p> <p>In sequential multi-slave mode more than one slave may be enabled. Slaves can also be suspended, which means they will be skipped during the transfer. This is used to avoid sending data to a slave while there is data in the transmit FIFO for the slave, so skipping data in the transmit FIFO. This register is only relevant in Master Mode.</p>

**Table 392. Transmit FIFO flush register (TX\_FIFO\_FLUSH, address 0x1500 2008)**

Bit	Symbol	Access	Reset Value	Description
31:1	-	-	0	Reserved
0	tx_fifo_flush	W	0	Transmit FIFO flush bit. In sequential multi-slave mode the transmit FIFO keeps its data by default. This means the FIFO needs to be flushed before changing the FIFO contents. 1: flush transmit FIFO 0: no action.

**Table 393. FIFO data register (FIFO\_DATA, address 0x1500 200C)**

Bit	Symbol	Access	Reset Value	Description
31:16	-	R/W	0	For write operation the value written to this field is ignored. On read, zero is returned in this field.
15:0	fifo_data	R/W	0	This register is used to access the FIFOs: Writing data puts new data in the transmit FIFO. Reading data reads a word from the receive FIFO. Note: the NHP registers can change the effect of reading this register.

**Table 394. NHP POP register (NHP\_POP, address 0x1500 2010)**

Bit	Symbol	Access	Reset Value	Description
31:1	-	-	0	Reserved.
0	nhp_pop	W		NHP pop bit Setting this bit will pop the first element from the receive FIFO. This is necessary in NHP mode because reading the FIFO_DATA register will not cause the receive FIFO pointer to be updated in this mode. (to protect the receive FIFO from losing data because of speculative reads). This bit will clear automatically.

**Table 395. NHP mode register (NHP\_MODE, address 0x1500 2014)**

Bit	Symbol	Access	Reset Value	Description
31:1	-	-	-	Reserved
0	nhp_mode	R/W	0	NHP mode bit. Setting this bit puts the SPI in 'NHP mode' and protects the receive FIFO contents from speculative reads. Now a read of the FIFO_DATA register only returns the data from the FIFO, but will not result in updating of the FIFO's read pointer as a side effect. Speculative reads of the FIFO_DATA register will not cause data loss of the received FIFO. After every read of data, the NHP pop register needs to be written, in order to remove the read element from the FIFO, and to point to the next element.  Clearing the bit disables the NHP mode. An explicit pop of the receive FIFO is no longer needed. Reading the FIFO_DATA register also updates the receive FIFO's read pointer as a side-effect.

**Table 396. DMA setting register (DMA\_SETTINGS, address 0x1500 2018)**

Bit	Symbol	Access	Reset Value	Description
31:8	-	-	0x0	Reserved.
7:5	-	-	0x0	Reserved.
4:2	-	-	0x0	Reserved.
1	tx_dma_enable	R/W	0	Tx DMA enable bit 1: DMA enabled 0: DMA disabled
0	rx_dma_enable	R/W	0	Rx DMA enable bit 1: DMA enabled 0: DMA disabled.

**Table 397. Status register (STATUS, address 0x1500 201C)**

Bit	Symbol	Access	Reset Value	Description
31:6	-	-	0	Reserved.
5	Sms_mode_busy	R	0	Sequential multi-slave mode busy flag 1: SPI is currently transmitting in sequential multi-slave mode, once all data to all slaves has been sent, this bit is cleared 0: SPI is not in sequential multi-slave mode or not busy transmitting in this mode.
4	spi_busy	R	0	SPI busy flag 1: SPI is currently transmitting and/or receiving or the transmit FIFO is not empty 0: SPI is idle.
3	rx_fifo_full	R	0	Receive FIFO full bit 1: receive FIFO full 0: receive FIFO not full.

**Table 397. Status register (STATUS, address 0x1500 201C) ...continued**

Bit	Symbol	Access	Reset Value	Description
2	rx_fifo_empty	R	1	Receive FIFO empty bit 1: receive FIFO empty 0: receive FIFO not empty.
1	tx_fifo_full	R	0	Transmit FIFO full bit 1: transmit FIFO full 0:transmit FIFO not full.
0	tx_fifo_empty	R	1	Transmit FIFO empty bit 1: transmit FIFO empty 0: transmit FIFO not empty.

**Table 398. Hardware information register (HW\_INFO, address 0x1500 2020)**

Bit	Symbol	Access	Reset Value [decimal]	Description
31	-	-	0	Reserved.
30	fifoimpl	R	0	For software usage: The FIFO memory implementation, 0=flipflops 1=SRAM.
29:26	num_slaves	R	3	For software usage: The maximum number of slaves supported by this hardware configuration (minus 1 encoded).
25:21	tx_fifo_width	R	16	For software usage: The width of the transmit FIFO of this hardware configuration (minus 1 encoded).
20:16	rx_fifo_width	R	16	For software usage: The width of the receive FIFO of this hardware configuration (minus 1 encoded).
15:8	tx_fifo_depth	R	64	
7:0	rx_fifo_depth	R	64	

## 4.2 SPI slave registers

**Table 399. Slave settings 1 (SLV0\_SETTINGS1, address 0x1500 2024; SLV1\_SETTINGS1, address 0x1500 202C; SLV2\_SETTINGS1, address 0x1500 2034)**

Bit	Symbol	Access	Reset Value	Description
31:24	inter_transfer_dly	R/W	0x0	The delay between transfers to this slave measured in serial clock cycles. This delay is minimal 0 serial clock cycles (SPI_SCK_OUT). This field is only relevant in master mode.
23:16	number_words	R/W	0x0	Number of words to send in sequential multi-slave mode. After this number of words have been transmitted to this slave the master starts transmitting to the next slave. If the sequential multi-slave mode is disabled this field is not used. (minus 1 encoded).  This field is only relevant in master mode.
15:8	clk_divisor2	R/W	0x2	Serial clock rate divisor 2: A value from 2 to 254 (lsb bit is hard-coded 0).
7:0	clk_divisor1	R/W	0x0	Serial clock rate divisor 1: A value from 0 to 255.

The serial clock frequency is derived from the IP clock frequency using the values, which are programmed in the clk\_divisor1 and clk\_divisor2 fields:

**Table 400. Slave settings 2 (SLV0\_SETTINGS2, address 0x1500 2028; SLV1\_SETTINGS2, address 0x1500 2030; SLV2\_SETTINGS2, address 0x1500 2038)**

Bit	Symbol	Access	Reset Value	Description
31:17	-	-	0	Reserved.
16:9	pre_post_cs_dly	R/W	0	Programmable delay that occurs twice in a transfer and is present between assertion of the chip select and transfer (sampling) of the first data bit AND between the transfer of the last data bit and de-assertion of chip select. The minimum delay is one serial clock cycle (SPI_SCK_OUT). This register is minus one encoded (0 gives a one cycle delay). This field is only relevant in SPI master mode.
8	cs_value	R/W	0	Chip select value between back-to-back transfers selection bit. 1: chip select has a steady state high value between transfers 0: chip select has a steady state low value between transfers  The period in which the chip select has this value is programmed in the inter_transfer_dly field of the SLVx_SETTINGS1 registered. This field is only relevant in SPI master mode.

**Table 400. Slave settings 2 (SLV0\_SETTINGS2, address 0x1500 2028; SLV1\_SETTINGS2, address 0x1500 2030; SLV2\_SETTINGS2, address 0x1500 2038)**

Bit	Symbol	Access	Reset Value	Description
7	transfer_format	R/W	0	Format of transfer 0: SPI format 1: SSI format.
6	spo	R/W	0	Serial clock polarity (only used if SPI mode is selected) 1: the serial clock has a steady state high value between transfers 0: the serial clock has a steady state low value between transfers.
5	sph	R/W	0	Serial clock phase (only used if SPI mode is selected). Determines on which edges of the serial clock data is captured during transfers. 1: first data bit is captured on the second clock edge transition of a new transfer 0: first data bit is captured on the first clock edge transition of a new transfer
4:0	word size	R/W	0x0	Word size of transfers to this slave (minus 1). SPI mode: 8/16 bits supported SSI mode: 4 ... 16 bits supported

- $F_{\text{SPI\_SCK}} = F_{\text{SPI\_CLK}} / (\text{clkdivisor2} \times (1 + \text{clkdivisor1}))$

However, in slave mode this formula does not count. The SPI\_CLK may never be smaller than 4 times serial clock. In case of an oversampling ratio of 4 this means that the SPI\_TXD transitions occur at the correct instant or at most one clock period of SPI\_CLK earlier. However, for higher oversampling ratios the transitions occur too early (in a range from oversampling ratio/2-2 to oversampling ratio/2-1 clock cycles of the slave's SPI\_CLK).

### 4.3 SPI interrupt registers

**Table 401. Interrupt threshold register (INT\_THRESHOLD, address 0x1500 2FD4)**

Bit	Symbol	Access	Reset Value	Description
31:16	-	-	0	Reserved.
15:8	tx_threshold	R/W	0	A transmit threshold level interrupt is requested when the transmit FIFO contains less than this number of elements. When the value is higher than the FIFO size the behaviour of the threshold interrupt is undefined.
7:0	rx_threshold	R/W	0	A receive threshold level interrupt is requested when the receive FIFO contains more than this number of elements. When the value is higher than the FIFO size the behaviour of the threshold interrupt is undefined.

**Table 402. Interrupt clear enable register (INT\_CLR\_ENABLE, address 0x1500 2FD8)**

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	0	Reserved.
4	clr_sms_int_enable	W	0	Writing '1' clears sequential multi-slave mode ready interrupt bit in the INT_ENABLE register.
3	clr_tx_int_enable	W	0	Writing '1' clears transmit threshold level interrupt bit in the INT_ENABLE register.
2	clr_rx_int_enable	W		Writing '1' clears receive threshold level interrupt bit in the INT_ENABLE register.
1	clr_to_int_enable	W	0	Writing '1' clears receive time-out interrupt bit in the INT_ENABLE register.
0	clr_ov_int_enable	W	0	Writing '1' clears receive overrun interrupt bit in the INT_ENABLE register.

Bit	Symbol	Access	Reset Value	Description
31:5	-	-	-	Reserved.
4	set_sms_int_status	W	-	Writing '1' sets sequential multi-slave mode ready interrupt bit in the INT_STATUS register.
3	set_tx_int_status	W	-	Writing '1' sets transmit threshold level interrupt bit in the INT_STATUS register.
2	set_rx_int_status	W	-	Writing '1' sets receive threshold level interrupt bit in the INT_STATUS register.
1	set_to_int_status	W	-	Writing '1' sets receive time-out interrupt bit in the INT_STATUS register
0	set_ov_int_status	W	-	Writing '1' sets receive FIFO overrun interrupt bit in the INT_STATUS register.

## 5. Functional description

The SPI module is a master or slave interface for synchronous serial communication with peripheral devices that have either Motorola SPI or Texas Instruments synchronous serial interfaces (SSI).

The SPI module performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information through the APB interface. The transmit and receive paths are buffered with FIFO memories. Serial data is transmitted on SPI\_TXD and received on SPI\_RXD.

The SPI module includes a programmable bit rate clock divider and prescaler to generate the serial output clock SPI\_SCK\_OUT from the input clock SPI\_CLK. The SPI operating mode, frame format, and word size are programmed through the SLVx\_SETTINGS registers.

A single combined interrupt request SPI\_INTREQ output is asserted if any of the interrupts are asserted and unmasked. All five interrupts also have a separate interrupt request line.

A set of DMA signals is provided for interfacing with a DMA controller.

Depending on the operating mode selected, the SPI\_CS\_OUT outputs operate as an active HIGH frame synchronization output for Texas Instruments synchronous serial frame format or an active LOW chip select for SPI.

## 5.1 Formats

Each data frame is between 4 and 16 bits long depending on the size of words

programmed, and is transmitted starting with the MSB. There are two basic frame types that can be selected:

- Texas Instruments synchronous serial (SSI)
- Motorola Serial Peripheral Interface (SPI).

For these formats, the serial clock (SPI\_SCK\_OUT) is held inactive while the SPI module is idle, and transitions at the programmed frequency only during active transmission or reception of data.

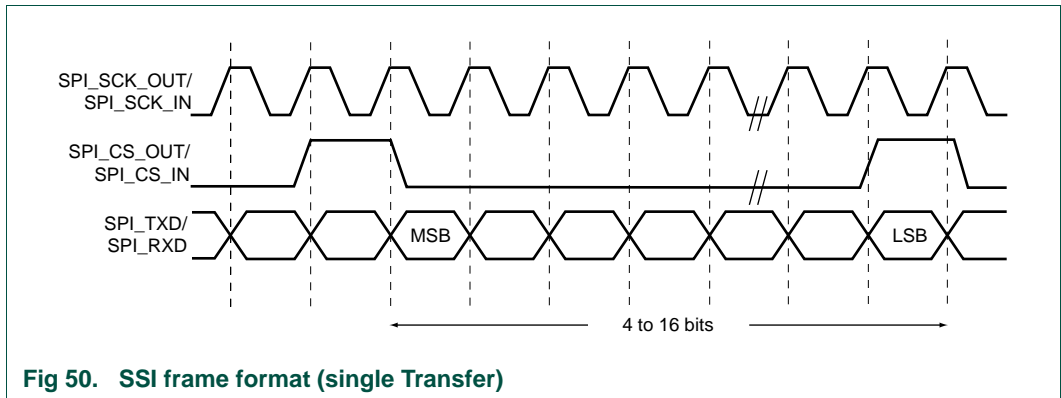

For Motorola SPI, the chip select pin (SPI\_CS\_OUT) is active low, and is asserted during the entire transmission of the frame.

For Texas Instruments SSI, the chip select pin (SPI\_CS\_OUT) is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SPI module and the off-chip slave device drive their output data on the rising edge of the serial clock pin, and latch data from the other device on the falling edge.

The next sections describe the frame formats in more detail. Note that in this sections 'delay1' is used to show the delay programmed in the pre\_post\_cs\_dly field of the SLVx\_SETTINGS2 register and "delay2" is used to show the delay programmed in the inter\_slave\_dly field of the SLVx\_SETTINGS1 register.

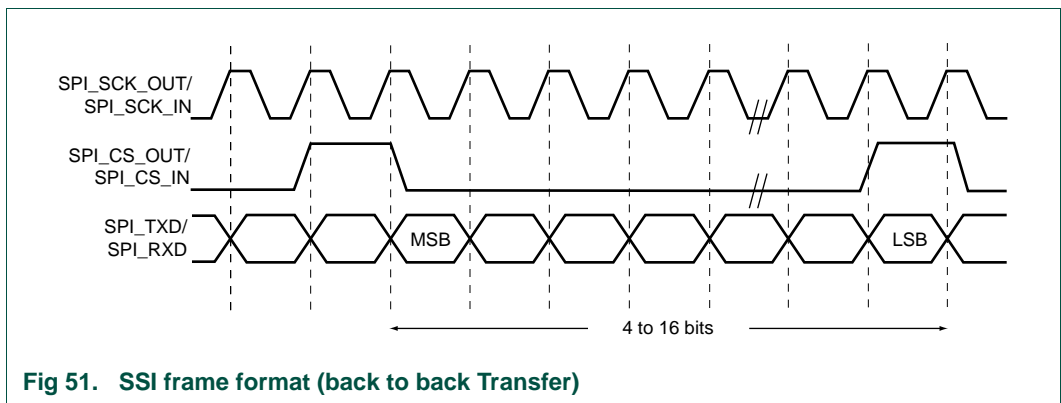

5.1.1 SSI Format

In this mode, the serial clock (SPI\_SCK\_OUT) and the chip select (SPI\_CS\_OUT) are forced LOW, and the transmission data line SPI\_TXD (in slave mode: SPI\_MISO, in master mode: SPI\_MOSI) tri-stated whenever the SPI module is idle. Once the bottom entry of the transmit FIFO contains data, SPI\_CS\_OUT is pulsed HIGH for one SPI\_SCK\_OUT period. The data to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SPI\_SCK\_OUT, the MSB of the 4 to 16-bit data frame is shifted out on the SPI\_TXD pin. Likewise, the MSB of the received data is shifted onto the SPI\_RXD pin by the off-chip serial slave device.

Both the SPI module and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each SPI\_SCK\_OUT. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SPI\_SCK\_OUT after the LSB has been latched.

The inter\_transfer\_dly field in the SLVx\_SETTINGS1 specifies the delay between back-to-back SSI transfers to the same slave. In Figure 20-51 this delay is zero cycles, the SPI\_CS\_OUT signal is asserted for signalling the beginning of the next transfer in the same cycle as the last bit of the previous transfer is transmitted. When the delay is programmed to be higher than 0, extra delay cycles are added before the next transfer will be started. During these delay cycles the SPI\_SCK\_OUT signal is low.

When a new slave is selected, there is a delay between the last transfer to the previous slave and the first transfer to the next slave. This delay is programmed in the `inter_slave_dly` field of the `SPI_CONFIG` register. In slave mode only zeros are transmitted in case of a FIFO under run.

**5.1.2 SPI Format**

The Motorola SPI interface is a four-wire interface where the `SPI_CS_OUT` signal behaves as a chip select. The main feature of the Motorola SPI format is that the inactive state and phase of the `SPI_SCK_OUT` signal are programmable through the `SPO` and `SPH` bits within the slave settings registers.

**SPO clock polarity**

When the `SPO` clock polarity control bit is `LOW`, it produces a steady state low value on the `SPI_SCK_OUT` pin. If the `SPO` clock polarity control bit is `HIGH`, a steady state high value is placed on the `SPI_SCK_OUT` pin when data is not being transferred.

**SPH clock phase**

The `SPH` control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.

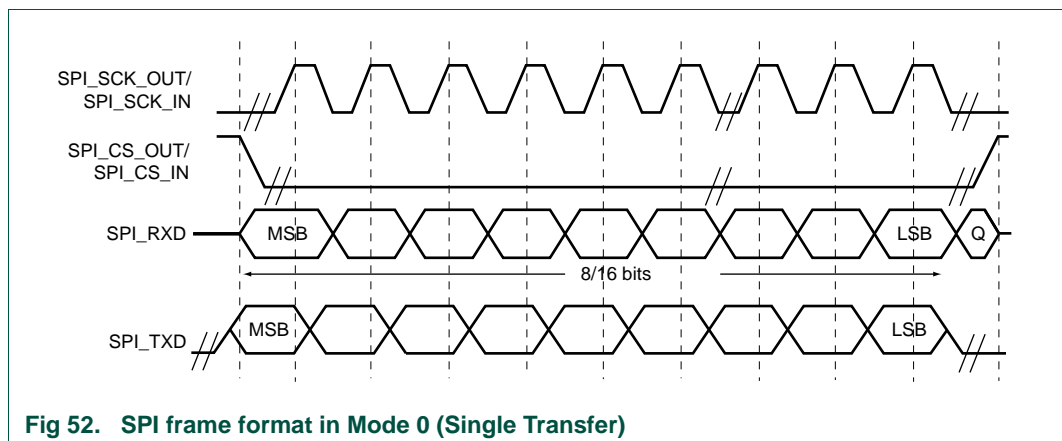

When the `SPH` phase control bit is `LOW`, data is captured on the first clock edge transition. If the `SPH` clock phase control bit is `HIGH`, data is captured on the second clock edge transition.

The values of these bits determine the 4 modes of the SPI:

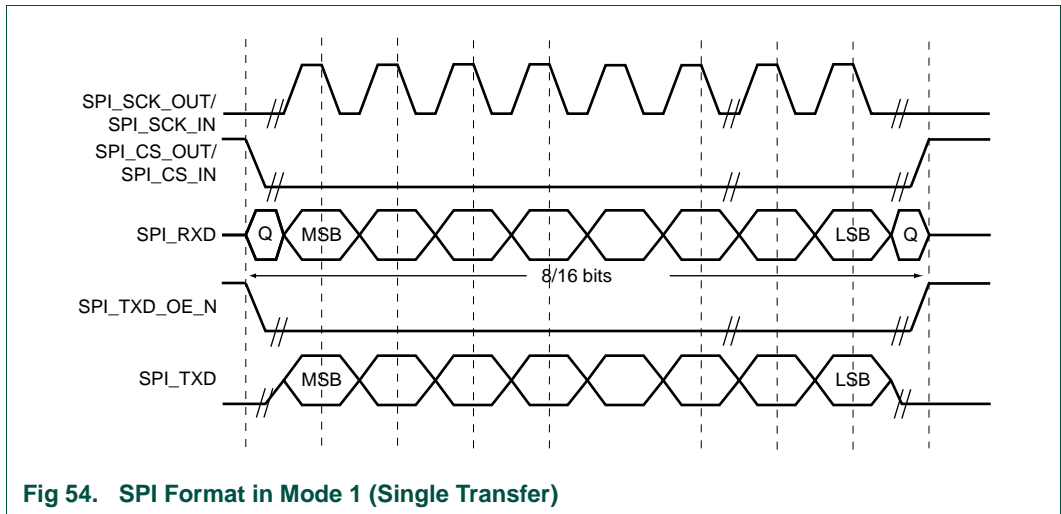

**Table 408. External Signals**

Mode	SPO	SPH
0 (00)	0	0
1 (01)	0	1
2 (10)	1	0
3 (11)	1	1

Single and continuous transmission signal sequences for Motorola SPI format in mode 0,1,2 and 3 are shown in [Figure 20–51](#) to [Figure 20–59](#) inclusive.

**Fig 52. SPI frame format in Mode 0 (Single Transfer)**

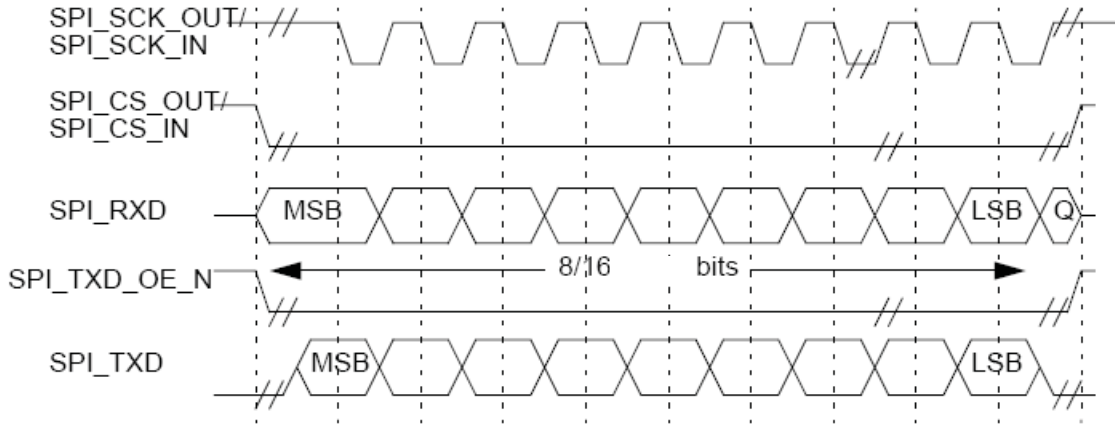

Fig 56. SPI Format in Mode 2 (Single Transfer)

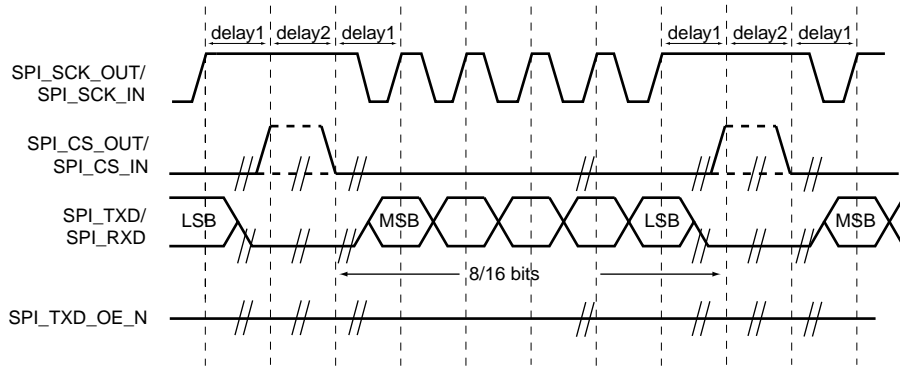

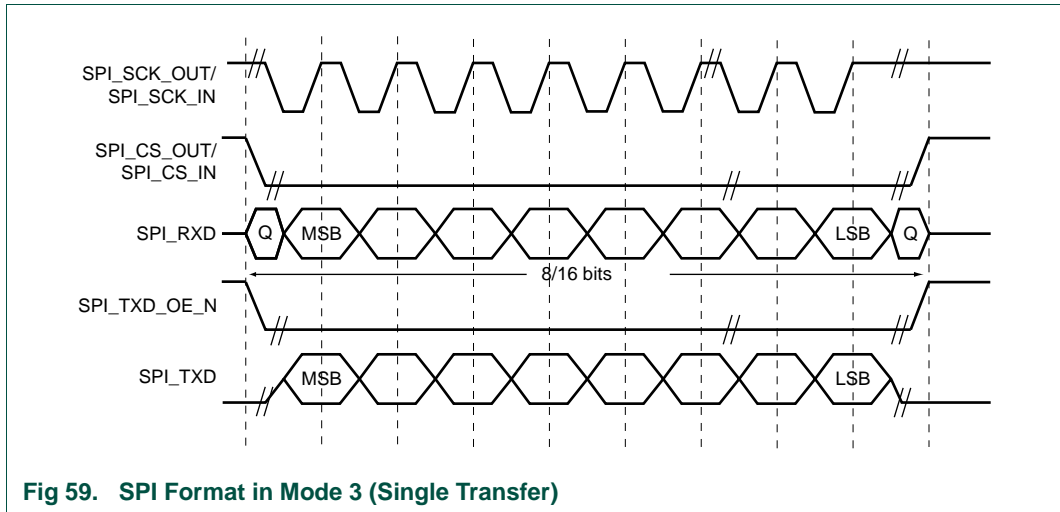

Fig 57. SPI Format in Mode 2 (Back to Back Transfer)

delay1 = pre\_post\_cd\_dly setting in [Table 20-400](#).

delay2 = inter\_transfer\_dly\_set in [Table 20-399](#)

Fig 58. SPI Format in Mode 3 (Back to Back Transfer)

**Fig 59. SPI Format in Mode 3 (Single Transfer)**

During idle periods:

- The SPI\_SCK\_OUT signal is forced low for mode 0 and 1. This signal is forced high for mode 2 and 3.
- SPI\_CS\_OUT is forced HIGH if no more data is present in the transmit FIFO. In case more data is to be transmitted (back-to-back transfer), the signal can be either forced high or low depending on a register setting which can be programmed differently for every slave
- The transmit data line SPI\_TXD is arbitrarily forced LOW
- The SPI\_TXD\_OE\_N pad enable signal is forced HIGH, making the transmit pad high impedance
- When the SPI module is configured as a master, the SPI\_SCK\_OE\_N is driven LOW, enabling the SPI\_SCK\_OUT pad (active LOW enable)
- When the module is configured as a slave, the SPI\_SCK\_OE\_N line is driven HIGH, disabling the SPI\_SCK\_OUT pad (active LOW enable).

If the SPI module is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SPI\_CS\_OUT master signal being driven LOW. This causes slave (which is enabled by the SLAVE\_ENABLE register) data to be enabled onto the SPI\_RXD line of the master. The SPI\_TXD\_OE\_N line is driven LOW, enabling the master SPI\_TXD output pad. After a minimum of half a SPI\_SCK\_OUT period, valid master data is transferred to the SPI\_TXD pin. Now that both the master and the slave data have been set, the SPI\_SCK\_OUT master clock pin becomes HIGH (mode 0,1)/LOW (mode 2, 3) after half a SPI\_SCK\_OUT period (= delay1). This delay is programmable and can be programmed for every slave differently. In this delay period no positive edges of the SPI\_SCK\_OUT clock signal occur. The same delay is applied after the last SPI\_SCK\_OUT positive edge of this transfer and possibly de-asserting of the SPI\_CS\_OUT signal.

For mode 0 and 2 the data is captured on the rising and propagated on the falling edges of the SPI\_SCK\_OUT signal. This is repeated 8 or 16 times depending on the programmed word size.

For mode 1 and 3 the data is captured on the falling and propagated on the rising edges of the SPI\_SCK\_OUT signal. This is repeated 8 or 16 times depending on the programmed word size.

In case of a single word transmission, after all bits of the data word have been transferred, the SPI\_CS\_OUT signal line is returned to its idle HIGH state after a minimum delay of 1 master clock period. This delay is programmable per slave and is equal to the delay between assertion of the SPI\_CS\_OUT signal and the first positive edge of the SPI\_SCK\_OUT clock signal.

In case of continuous back-to-back transmissions, the SPI\_CS\_OUT signal may (after the before mentioned delay of minimal 1 period) be asserted between transfers or not. Delay 2 shows the period in which there might be a SPI\_CS\_OUT pulse or not. This delay is minimal zero SPI\_SCK\_OUT master clock cycles and is programmable for every slave separately.

On completion of a back-to-back transfer, the SPI\_CS\_OUT pin is returned to its idle state after the minimal delay of one SPI\_SCK\_OUT period.

If after a transfer, another slave is selected, there is a programmable delay in SPI\_SCK\_OUT cycles between de-assertion of the chip select of the previous slave, and assertion of the chip select of the new slave.

In slave mode, only zeros are transmitted in case of a FIFO under run.

## 5.2 Operation Modes

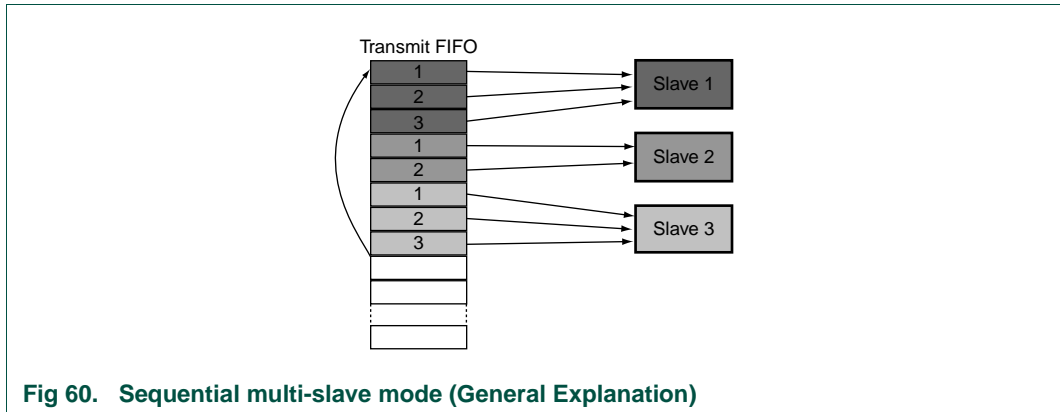

The module (in master mode) supports two modes of operation. One is the normal transmission mode in which software intervention is needed every time a new slave needs to be addressed and some interrupt handling.

The second operation mode is the sequential multi-slave mode. This mode reduces software intervention and interrupt load. Another advantage is that the data in the transmit FIFO can be transmitted again without the need of re-filling the FIFO, which reduces bus load.

### 5.2.1 Sequential Multi-Slave Mode

In this mode it is possible to sequentially transmit data to different slaves without having to re-program the module between transfers to different slaves. The purpose of this mode is to minimize interrupts/software intervention and bus traffic. This mode is only applicable when the module is in master mode.

In the example in [Figure 20–60](#) the module supports addressing of three slaves. All three slaves are sent data in sequential multi-slave mode. Three elements are transferred to slave 1, two to slave 2, and three to slave 3. Now the module disables itself. When it is enabled again the same data is transmitted to the three slaves.

**Fig 60. Sequential multi-slave mode (General Explanation)**

Before entering this mode the transmit data needs to be present in the transmit FIFO. No data may be added after entering sequential multi-slave mode. When the data to be transferred needs to be changed the transmit FIFO must be flushed and sequential multi-slave mode is left and entered again to 'save' the new data present in the transmit FIFO. This is necessary because the FIFO contents are saved as a side-effect of entering sequential multi-slave mode from normal transmission mode. The data in the transmit FIFO is saved to allow transmitting it multiple times without the need to re-fill it with the same data.

All programming of the settings necessary to adapt to all slaves has to be done before enabling (starting the transfer) the module in sequential multi-slave mode. Once a transfer has started these settings may not be changed until the module has finished the transfer and is automatically disabled again. You can select only one slave in this mode.

Once a sequential multi-slave mode transfer has started it finishes completely, even if the module gets disabled before the transfer is over. When a transfer is finished, the module disables itself and requests a sequential multi-slave mode ready interrupt.

You can temporarily suspend/skip one or more of the slaves in a transfer. The data in the transmit FIFO does not need to be flushed. During the transfer this data will be skipped and on the serial interface nothing happens for the exact time that would have been used by transferring to the skipped slave. In the receive FIFO dummy (zero filled) words are written. The number of dummy words is equal to the number of words that would have been received by the suspended slave. When suspending slaves it is important to keep the corresponding SLVx\_SETTINGS. The numbers\_words field is necessary to skip the data for this slave. The other settings are needed to create the delay of the suspended transfer on the serial interface. Suspending a slave does not change anything for the duration of a sequential multi-slave transfer.

A slave can also be completely disabled. The transmit FIFO may not hold any data for this slave, which means the transmit FIFO may need to be flushed and re-programmed. The SLVx\_SETTINGS for a disabled slave are ignored.

Setting up the sequentially multi-slave mode transfer:

- Programming the settings for transmitting to different slaves. Every slave can have different settings like SPI/TI mode, different word size or baud rates. The registers SLVx\_SETTINGS1 and SLVx\_SETTINGS2 are duplicated for the number of slaves

that are supported by the module. In SLVx\_SETTINGS1 also the number of words to transmit to this slave must be programmed. These settings may not be changed during a sequential multi-slave mode transfer.

- Writing the transmit data to the transmit FIFO. All data for all slaves must be present before entering sequential multi-slave mode. The contents of the transmit FIFO is 'saved' when entering this mode to allow sending the same data multiple times without having to re-fill the FIFO with the same data. If the data in the transmit FIFO needs to be changed the FIFO first needs to be flushed using the TX\_FIFO\_FLUSH register. Note that when changing the slaves that are enabled/disabled or the number of elements to send to each slave, the transmit FIFO contents must be changed. After writing new data to the transmit FIFO the multi-sequence mode is left and entered again to 'save' the new data.
- Enabling/disabling/suspending slaves. In sequential multi-slave mode order of transmission is fixed. First slave 1 is addressed, then slave 2, until the last slave is reached. By programming the SLAVE\_ENABLE register it can be specified which slave to address and which slaves to skip. Writing a '01' enables the corresponding slave and a '00' disables the corresponding slave. Note that when a slave is disabled, no data for this slave must be written to the transmit FIFO. The SLVx\_SETTINGS register settings for a disabled slave are ignored. Writing '11' suspends/skips the corresponding slave. The data for this slave is still present in the transmit FIFO, is skipped. The SLVx\_SETTINGS register settings for a suspended slave are still used to skip the data in the FIFO for this slave and to create a delay on the serial interface equal to the delay that would be used for transmitting to the suspended/skipped slave. Because a new value is written to the SLAVE\_ENABLE register the update\_enable bit in the SPI\_CONFIG register must be set.
- Enabling/disabling DMA. The transmit DMA requests must be disabled. All transmit data should be present before enabling the SPI module so transmit DMA requests are not necessary. The receive DMA request can be enabled. But the receive FIFO can also be read only after the sequential multi-slave mode has finished, which requires the receive DMA request to be disabled.
- Enabling the sequential multi-slave mode ready interrupt request. This interrupt signals the end of a sequential multi-slave transfer. After a transfer the receive FIFO needs to be read, before a new transfer starts. If the new transfer can start before the receive FIFO is empty, the receive FIFO needs to be sized as such.
- Setting the transmit mode bit (SPI\_CONFIG register). Setting this bit 'saves' the transmit FIFO contents (so it can be transmitted multiple times without re-filling) and enter the sequential multi-slave mode. This prevents FIFO overruns.
- Enabling the MODULE. Once the SPI module is enabled in sequential multi-slave mode it sends its transmit data to the slaves that are enabled. It will automatically re-program its settings if needed to adapt to different slaves. When all data has been transmitted, the sequential multi-slave ready interrupt is requested. The update\_enable bit in the SPI\_CONFIG register is cleared to allow re-programming of the SLAVE\_ENABLE register. Now the receive FIFO needs to be emptied to allow a new transfer to be started. The SPI module disables itself and wait until it is enabled again to start a new transfer. After it is enabled again, it transmits the same data, unless the transmit FIFO is filled with new data after flushing the FIFO.
- Setting the enable bit in the SPI\_CONFIG register enables the module in sequential multi-slave mode. If the sequential multi-slave mode needs to be left, the transmit mode bit in the SPI\_CONFIG register has to be cleared. Also the transmit FIFO needs

to be flushed to allow its contents to be changed. If not in sequential multi-slave mode, only one slave may be enabled in the SLAVE\_ENABLE register. Once the sequential multi-slave mode has been left, the module is in normal transmission mode.

### 5.2.2 Normal Transmission Mode

When the module is used as a master and is not programmed to be in sequential multi-slave mode, it is in normal transmission mode. In this mode software programs the settings of the SPI module, writes data to the transmit FIFO and then enables the module. The module transmits until all data has been sent or until it gets disabled before all data has been sent. When data needs to be transmitted to another slave, software needs to re-program the settings of the module, write new data and enable the module again. This mode requires software intervention every time a new slave needs to be addressed and more interrupt handling.

**Remark:** When re-programming any of the settings the module must be disabled first.

After changing the settings it can be enabled again. Transmit data can also be added when the module is still enabled, disabling is not necessary in this case.

Setting up a normal transmission mode transfer:

- Programming of the settings necessary to adapt to the slave. In the SLVx\_SETTINGS1 and SLVx\_SETTINGS2 register the settings for every slave can be programmed. The registers corresponding to the slave to be addressed will need to be programmed. The 'number\_words' field of SLV\_REGISTER1 is not needed in this mode of transmission and is ignored.
- Enabling the slave to be addressed in the SLAVE\_ENABLE register. The bits in this register corresponding to the slave to be addressed needs to be set to '01'. Note that in normal transmission mode only one slave may be enabled. Setting more than one bit will result in undefined behavior. After programming the SLAVE\_ENABLE register the update\_enable bit in the SPI\_CONFIG register needs to be set.
- Enabling the module by setting the enable bit in the SPI\_CONFIG register.
- Writing data to the transmit FIFO. Once data is in the transmit FIFO and the module is enabled the module starts transmitting. Transmit data may also be written to the transmit FIFO before enabling the module.
- When a new slave needs to be addressed the module needs to be disabled. The SLVx\_SETTINGS registers corresponding to the new slave must be programmed and the new slave must be enabled (and previous slave disabled) in the SLAVE\_ENABLE register. If the module is disabled during a pending transfer the data being transferred is lost.

### 5.2.3 Slave Mode

The module can be used in slave mode by setting the 'ms\_mode' bit in the SPI\_CONFIG register. The settings of the slave can be programmed in the SLV1\_SETTINGS registers that would correspond to slave 1 (offsets 0x024 and 0x028). A slave must be programmed to be in normal transmission mode. SLAVE\_ENABLE register is ignored in slave mode.

## 6. Power optimization

---

The SPI module has an asynchronous clock domain crossing allowing the APB clock frequency to be independent from the IP clock frequency. This allows power saving by lowering the APB bus frequency while receiving and transmitting on the serial interface with the same unchanged frequency.

For more power saving the oversampling ratio has to be set as low as possible to lower the SPI\_CLK frequency.

The module has clock gating. The gated clocks are requested when necessary. They are requested as long as there is data in the transmit FIFO, or the serial interface control blocks remain busy. Setting the external enabling bit of PCR CGU registers of these clocks enables their clock gating.

## 7. Programming guide

---

To set-up a normal transmission the following registers have to be programmed.

- Program the settings in the SLVx\_SETTINGS1 and SLVx\_SETTINGS2
- Enable the slave to be addressed in the SLAVE\_ENABLE register. When the module is slave the value 0x01 has to be written to this register. The number of the enabled slave determines which SLVx\_SETTINGS1 and SLVx\_SETTINGS2 are invoked
- Program the module as slave or master by (re-)setting the ms\_mode bit in the SPI\_CONFIG register.
- To start the data transmission directly when data is available in the FIFO, enable the module by setting the enable bit in the SPI\_CONFIG register.
- Write data to the FIFO\_DATA register. Once data in the FIFO, the data is transmitted if the module is the master.
- When a new slave has to be addressed the module must be disabled and the previous programming has to be re-done.

## 1. Introduction

---

MCI is an interface between the AHB and the memory card. It supports Secure Digital memory (SD Mem), Secure Digital I/O (SDIO), Multimedia Cards (MMC), and Consumer Electronics Advanced Transport Architecture (CE-ATA).

### 1.1 Features

This module has the following features:

- One 8-bit wide interface.
- Supports high-speed SD, versions 1.01, 1.10 and 2.0.
- Supports SDIO version 1.10.
- Supports MMCplus, MMCmobile, and MMCmicro cards based on MMC 4.1.
- Supports SDHC memory cards.
- CRC generation and checking.
- Supports 1/4-bit SD cards.
- Card detection and write protection.
- FIFO buffers of 16 bytes deep.
- Host pull-up control.
- SDIO suspend and resume.
- 1-byte to 65 535-byte blocks.
- Suspend and resume operations.
- SDIO Read-wait.
- Maximum clock speed of 52 MHz (MMC 4.1).
- Supports CE-ATA 1.1.
- Supports 1-bit, 4-bit, and 8-bit MMC cards and CE-ATA devices.

## 2. General description

---

### 2.1 Block diagram

The module consists of the following main functional blocks, which are illustrated in the figure below.

- Bus Interface Unit (BIU) - Provides AHB and DMA interfaces for register and data read/writes.
- Card Interface Unit (CIU) - Takes care of the card protocols and provides clock management.

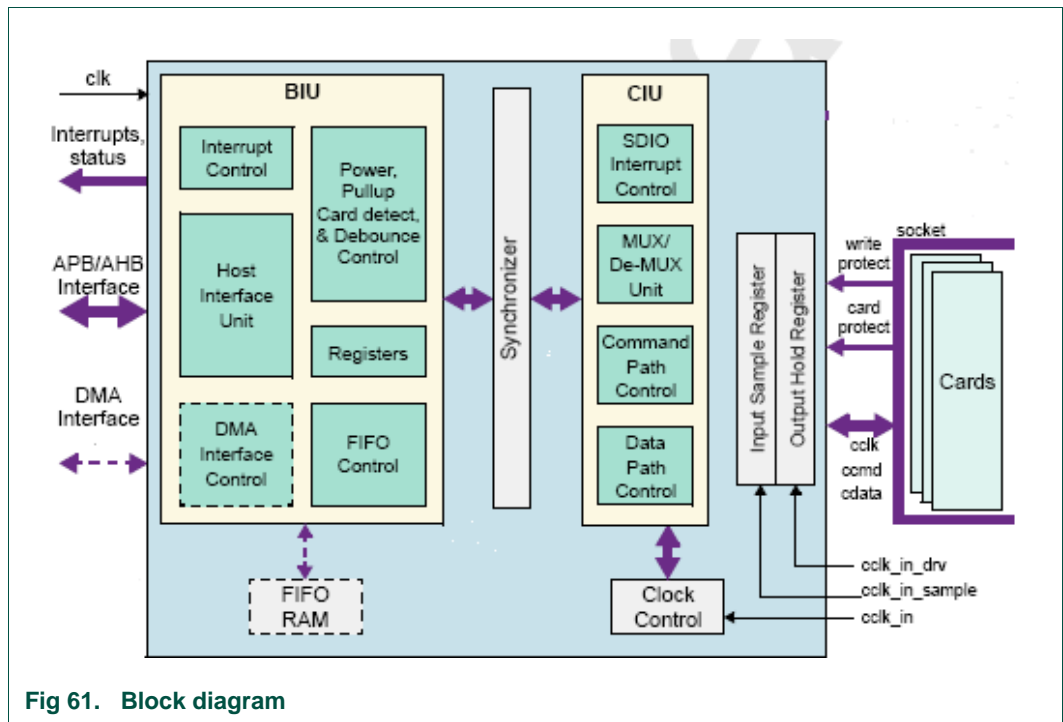

Fig 61. Block diagram

## 2.2 Interface description

### 2.2.1 Clock signals

Table 409. Clock signals of the MCI module

Clock name	Acronym	I/O	Source/destination	Description
SD_MMC_HCLK	CLK	I	CGU	AHB interface clock of the module. The AHB interface logic in this module runs on this clock. The maximum frequency of AHB_CLK is 75MHz. This clock is synchronous to cclk_in.
SD_MMC_CCLK_IN	CCLK_IN	I	CGU	Card interface input clock. The card interface input clock and CLK frequencies should meet a "CLK>=1/10 CCLK_IN" requirement. The maximum operating frequency of a SD card is 25 MHz, and a MMC-Ver4.0 card is 26 MHz or 52 MHz. This clock is synchronous to clk.

Table 409. Clock signals of the MCI module ...continued

Clock name	Acronym	I/O	Source/ destination	Description
SD_MMC_CCLK_IN  _SAMPLE	CCLK_IN_SAMPLE	I	MCI_CLK (PAD)	Delayed CCLK_IN to sample card inputs. Card input sampling clock is used for clocking card inputs. Since card inputs are guaranteed to meet only setup-and-hold time with regard to card output clock on its PAD, delayed version of cclk_in is needed to sample all card inputs.  The cclk_in to cclk_in_sample delay should match cclk_in to cclk_out delay of core, plus cclk_out PAD delay, plus data/cmd pad input PAD delay. (MMC cards required to provide 3ns setup and 3ns hold on inputs; SD cards required to provide 5ns setup and 5ns hold on all inputs). Therefore the cclk_in_sample is derived from the cclk_out. The delay in clock is configured using SYSCREG_MCI_DELAYMODES register SYSCREG block.
SD_MMC_CCLK_IN _DRV	CCLK_IN_DRV	I	MCI_CLK (pad)	Delayed CCLK_OUT to drive card outputs. Card outputs driving clock is used for clocking optional hold-time registers. The delay should be ~5ns of cclk_out for SD cards, 2 ns for high-speed SD cards and 3 ns for (H)MMC and CE-ATA. (Cards need x ns holds on all inputs, so all outputs clocked out of cclk_in are re-clocked by cclk_in_drv to meet card hold-time requirement.). The cclk_in_drv is derived from the cclk_out.
SD_MMC_CCLK_O UT	CCLK_OUT	O	MCI_CLK (PAD)	Card clock. This clock is the input clock of the cards, SD, (H)MMC and CE-ATA.

## 2.2.2 Bus interface

The MCI is connected to the AHB bus.

## 2.2.3 Pin connections

Table 410. External signals of the MCI module

Pin name	MCI pin name <sup>[1]</sup>	Type	Reset value	Description
mGPIO5	MCI_CLK	I/O		Card clock and used as input for cclk_in_sample and cclk_in_drv.
mGPIO6	MCI_CMD	I/O	-	Card command in-/output.
mGPIO7	MCI_DAT_0	I/O	-	Card data in-/output.
mGPIO8	MCI_DAT_1	I/O	-	Card data in-/output.
mGPIO9	MCI_DAT_2	I/O	-	Card data in-/output.
mGPIO10	MCI_DAT_3	I/O	-	Card data in-/output.
mNAND_RYBN0	MCI_DAT_4	I/O	-	Card data in-/output.
mNAND_RYBN1	MCI_DAT_5	I/O	-	Card data in-/output.
mNAND_RYBN2	MCI_DAT_6	I/O	-	Card data in-/output.
mNAND_RYBN3	MCI_DAT_7	I/O	-	Card data in-/output.

[1] The MCI pins are multiplexed with GPIO and NAND flash pins.

## 2.2.4 Interrupt request signals

Table 411. Interrupt request signals of the MCI module

Name	Type	Description
INTRRUPT	0	Combined active-high, level-sensitive CPU interrupt

## 2.2.5 Reset signals

The CGU provides a system active-low reset pin; synchronous to clk. Should be kept active at least 12 clocks or cclk\_in, whichever is lower frequency. The reset\_n is the result of OR function of sd\_mmc\_pnres and sd\_mmc\_nres\_cclk\_in. The reset signal sd\_mmc\_pnres is a low active synchronous reset to clk. The reset signal sd\_mmc\_nres\_cclk\_in is a low active synchronous reset to cclk\_in.

## 2.2.6 DMA transfer signals

Table 412. DMA signals of the MCI module

Name	Type	Description
SD_MMC__DMA_REQ	0	DMA

## 2.2.7 System control register (SysCReg) signals

Table 413. Number of delay cells in the MCI (delay) module (see [Table 27–542](#))

Name	Type	Description
MCI_DELAYMODES[4:0]	I	This bus-signal specifies the number of delay cells to obtain the needed delay for cclk_in_drv. The delay should be ~5ns in comparison to cclk_out for SD cards, 2 ns for high-speed SD cards and 3 ns for (H)MMC and CE-ATA. (Cards need x ns holds on all inputs, so all outputs clocked out of cclk_in are re-clocked by cclk_in_drv to meet card hold-time requirement.).

Table 414. Configuration signals of MCI module (see [Table 27–541](#))

Name	Type	Description
CARD_WRITE_PRT	I	Card write protect signal for SD cards. A 1 represents write is protected. Default is zero. Software must honor write-protect. This signal is set by setting the BIT[0] in SYSCREG_SD_MMC_CFG configuration register in SYSCREG module. Software should program this bit by detecting the event from unused external GPIO pin. So that the SD_MMC module responds to the event.
CARD_DETECT_N	I	Card detect signal. A 0 represents presence of card. Default is one. Any change in this signal will cause card_detect interrupt, if enabled. This signal is set by setting the BIT[1] in SYSCREG_SD_MMC_CFG configuration register in SYSCREG module. Software should program this bit by detecting the event from unused external GPIO pin. So that the SD_MMC module responds to the event.

### 3. Register overview

**Table 415. Register overview: MCI (register base address 0x1800 0000)**

Name	R/W	Address offset	Description	Reset value
CTRL	R/W	0x000	Control register.	0x0
PWREN	R/W	0x004	reserved	-
CLKDIV	R/W	0x008	Clock-divider register	0x0
CLKSRC	R/W	0x00C	Clock-source register	0x0
CLKENA	R/W	0x010	Clock-enable register	0x0
TMOUT	R/W	0x014	Time-out register (number of card clock output clocks – cclk_out)	0xFFFFFFFF40
CTYPE	R/W	0x018	Card-type register	0x0
BLKSIZ	R/W	0x01C	Block-size register	0x200
BYTCNT	R/W	0x020	Byte-count register	0x200
INTMASK	R/W	0x024	Interrupt-mask register	0x0
CMDARG	R/W	0x028	Command-argument register	0x0
CMD	R/W	0x02C	Command register	0x0
RESP0	R	0x030	Response-0 register	0x0
RESP1	R	0x034	Response-1 register	0x0
RESP2	R	0x038	Response-2 register	0x0
RESP3	R	0x03C	Response-3 register	0x0
MINTSTS	R	0x040	Masked interrupt-status register	0x0
RINTSTS	R/W	0x44	Raw interrupt-status register	0x0
STATUS	R	0x48	Status register; mainly for debug purposes	{20'h00000, 4'b00xx, 8'h06}
FIFOTH	R/W	0x4C	FIFO threshold register	{4'h0, bits[27:16] = FIFO_DEPTH - 1 bits[15:0] = 0}
CDETECT	R	0x50	Card-detect register	Value in card_detect signal
WRTPRT	R	0x54	Write-protect register	Value in card_write_prt signal
-	R/W	0x58	reserved	-
TCBCNT	R	0x5C	Transferred CIU card byte count	0x0
TBBCNT	R	0x60	Transferred cpu/DMA to/from BIU-FIFO byte count	0x0
Reserved	-	0x64 - 0xFF	-	-
DATA	R/W	>= 0x100 <a href="#">[1]</a>	Data FIFO read/write; if address is equal or greater than 0x100, then FIFO is selected as long as device is selected (hsel active)	32'hx

[1] Address 0x100 and above are mapped to data FIFO. More than one address is mapped to data FIFO so that FIFO can be accessed using AMBA bursts.

## 4. Register description

Table 416. Control register (CTRL, address 0x1800 0000)

Bit	Symbol	Access	Reset value	Description
31:12	-	-	-	Reserved
11	ceata_device_interrupt_status		0	<p>0 – Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register)</p> <p>1 – Interrupts are enabled in CE-ATA device (nIEN = 0 in ATA control register)</p> <p>Software should appropriately write to this bit after power-on reset or any other reset to CE-ATA device. After reset, usually CE-ATA device interrupt is disabled (nIEN = 1). If the cpu enables CE-ATA device interrupt, then software should set this bit.</p>
10	send_auto_stop_ccsd		0	<p>0 – Do not send internally generated STOP command (CMD12) after sending Command Completion Signal Disable (CCSD) to CE-ATA device.</p> <p>1 – Send internally generated STOP after sending CCSD to CE-ATA device.</p> <p>Always set send_auto_stop_ccsd and send_ccsd bits together; send_auto_stop_ccsd should not be set independent of send_ccsd.</p> <p>When set, the module automatically sends internally generated STOP command (CMD12) to CE-ATA device. After sending internally-generated STOP command, Auto Command Done (ACD) bit in RINTSTS is set and generates interrupt to cpu if Auto Command Done interrupt is not masked. After sending the CCSD, the module automatically clears send_auto_stop_ccsd bit.</p>
9	send_ccsd		0	<p>0 – Do not send Command Completion Signal Disable (CCSD) to CE-ATA device.</p> <p>1 – Send Command Completion Signal Disable (CCSD) to CE-ATA device</p> <p>When set, the module sends CCSD to CE-ATA device. Software sets this bit only if current command is expecting CCS (that is, RW_BLK) and interrupts are enabled in CE-ATA device. Once the CCSD pattern is sent to device, the module automatically clears send_ccsd bit. It also sets Command Done (CD) bit in RINTSTS register and generates interrupt to cpu if Command Done interrupt is not masked.</p>
8	Abort_read_data		0	<p>0 – No change</p> <p>1 – After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs, software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data state machine resets to idle.</p>

Used in SDIO card suspend sequence.

Table 416. Control register (CTRL, address 0x1800 0000) ...continued

Bit	Symbol	Access	Reset value	Description
7	Send_irq_reponse		0	0 – No change 1 – Send auto IRQ response  Bit automatically clears once response is sent. To wait for MMC card interrupts, cpu issues CMD40, and the module waits for interrupt response from MMC card(s). In meantime, if cpu wants the module to exit waiting for interrupt state, it can set this bit, at which time the module command state-machine sends CMD40 response on bus and returns to idle state.
6	Read_wait		0	0-- Clear read wait 1 – Assert read wait For sending read-wait to SDIO cards.
5	Dma_enable		0	0 – Disable DMA transfer mode 1 – Enable DMA transfer mode  Even when DMA mode is enabled, cpu can still push/pop data into/from FIFO. If there is simultaneous FIFO push from CIU, DMA, and cpu (which should not happen in normal operation), priority is as follows: CIU, DMA, and cpu. Same priority given for FIFO pop.
4	Int_enable		0	Global interrupt enable/disable bit: 0 – Disable interrupts 1 – Enable interrupts  The interrupt port is 1 only when this bit is 1 and one or more unmasked interrupts are set.
3	-	-	-	Reserved

**Table 416. Control register (CTRL, address 0x1800 0000) ...continued**

Bit	Symbol	Access	Reset value	Description
2	Dma_reset		0	0 – No change 1 – Reset internal DMA interface control logic  To reset DMA interface, firmware should set bit to 1. This bit is auto-cleared after two AHB clocks.
1	Fifo_reset		0	0 – No change 1 – Reset to data FIFO To reset FIFO pointers  To reset FIFO, firmware should set bit to 1. This bit is auto-cleared after completion of reset operation.
0	Controller_reset		0	0 – No change 1 – Reset Module controller  To reset controller, firmware should set bit to 1. This bit is auto-cleared after two AHB and two cclk_in clock cycles. This resets: * BIU/CIU interface * CIU and state machines * abort_read_data, send_irq_response, and read_wait bits of Control register * start_cmd bit of Command register Does not affect any registers or DMA interface, or FIFO or cpu

**Table 417. Clock divider register (CLKDIV, address 0x1800 0008)**

Bit	Symbol	Access	Reset value	Description
31:8	-	-	-	Reserved
7:0	Clk_divider	R/W	0	Clock divider-0 value. Clock division is $2 \times n$ . For example, value of 0 means no division (bypass), value of 1 means divide by $2 \times 1 = 2$ , value of FF means divide by $2 \times 255 = 510$ , and so on.

**Table 418. Clock source register (CLKSRC, address 0x1800 000C)**

Bit	Symbol	Access	Reset value	Description
31:2	-	-	-	Reserved
1:0	Clk_source	R/W	0x0	The value of this register has to be kept at zero (0x0).

**Table 419. Clock enable register (CLKENA, address 0x1800 0010)**

Bit	Symbol	Access	Reset value	Description
31:17	-	-	-	Reserved
16	Cclk_low_power	R/W	0x0	Low-power control for the output card clock: 0 – Non-low-power mode 1 – Low-power mode; stop clock when card in IDLE (should be normally set to only MMC and SD memory cards; for SDIO cards, if interrupts must be detected, clock should not be stopped).
15:1	-	-	-	Reserved
0	Cclk_enable	R/W	0	Clock-enable control for the output card clock: 0 – Clock disabled 1 – Clock enabled

**Table 420. Timeout register (TMOUT, address 0x1800 0014)**

Bit	Symbol	Access	Reset value	Description
31:8	Data_timeout	R/W	0xFFFFFFFF	Value for card Data Read Timeout; same value also used for Data Starvation by Cpu timeout. Value is in number of card output clocks – cclk_out of selected card.
7:0	Response_timeout	R/W	0x40	Response timeout value. Value is in number of card output clocks – cclk_out.

**Table 421. Card type register (CTYPE, address 0x1800 0018)**

Bit	Symbol	Access	Reset value	Description
31:17	-	-	-	Reserved
16	Card_width	R/W	0x0	This bit indicates if the card is 8-bit: 0 – Non 8-bit mode 1 – 8-bit mode
15:1	-	-	-	Reserved
0	Card_width	R/W	0	This bit indicates if the card is 1-bit or 4-bit: 0 – 1-bit mode 1 – 4-bit mode

The following examples use values for CTYPE[16]:

- If CTYPE[16] = 1, the card is in 8-bit mode. Note that the CTYPE[0] value is ignored; it is recommended to keep this set to 0.

- If CTYPE[16] = 0, the card is in either 1-bit or 4-bit mode, depending upon the value of CTYPE[0]; that is, if CTYPE[0] = 1 - 4-bit, CTYPE[0] = 0 - 1-bit.

**Table 422. Blocksize register (BLKSIZ, address 0x1800 001C)**

Bit	Symbol	Access	Reset value	Description
31:16	-	-	-	Reserved
15:0	Block_size	R/W	0x200	Block size

**Table 423. Byte count register (BYCNT, address 0x1800 0020)**

Bit	Symbol	Access	Reset value	Description
31:0	Byte_count	R/W	0x200	Number of bytes to be transferred; should be integer multiple of Block Size for block transfers.  For undefined number of byte transfers, byte count should be set to 0. When byte count is set to 0, it is responsibility of cpu to explicitly send stop/abort command to terminate data transfer.

**Table 424. Interrupt mask register (INTMASK, address 0x1800 0024)**

Bit	Symbol	Access	Reset value	Description
31:17	-	-	-	Reserved
16	SDIO	R/W	0	Mask SDIO interrupt When masked, SDIO interrupt detection for the card is disabled. A 0 masks an interrupt, and 1 enables an interrupt.
15	EBE	R/W	0	End-bit error (read)/Write no CRC (EBE). A 0 masks an interrupt, and 1 enables an interrupt.
14	ACD	R/W	0	Auto command done (ACD). A 0 masks an interrupt, and 1 enables an interrupt.
13	SBE	R/W	0	Start-bit error (SBE). A 0 masks an interrupt, and 1 enables an interrupt.
12	HLE	R/W	0	Hardware locked write error (HLE). A 0 masks an interrupt, and 1 enables an interrupt.
11	FRUN	R/W	0	FIFO underrun/overflow error (FRUN). A 0 masks an interrupt, and 1 enables an interrupt.
10	HTO	R/W	0	Data starvation-by-cpu timeout (HTO). A 0 masks an interrupt, and 1 enables an interrupt.
9	DRTO	R/W	0	Data read timeout (DRTO). A 0 masks an interrupt, and 1 enables an interrupt.
8	RTO	R/W	0	Response timeout (RTO). A 0 masks an interrupt, and 1 enables an interrupt.
7	DCRC	R/W	0	Data CRC error (DCRC). A 0 masks an interrupt, and 1 enables an interrupt.
6	RCRC	R/W	0	Response CRC error (RCRC). A 0 masks an interrupt, and 1 enables an interrupt.
5	RXDR	R/W	0	Receive FIFO data request (RXDR). A 0 masks an interrupt, and 1 enables an interrupt.

**Table 424. Interrupt mask register (INTMASK, address 0x1800 0024) ...continued**

Bit	Symbol	Access	Reset value	Description
4	TXDR	R/W	0	Transmit FIFO data request (TXDR). A 0 masks an interrupt, and 1 enables an interrupt.
3	DTO	R/W	0	Data transfer over (DTO). A 0 masks an interrupt, and 1 enables an interrupt.
2	CD	R/W	0	Command done (CD). A 0 masks an interrupt, and 1 enables an interrupt.
1	RE	R/W	0	Response error (RE). A 0 masks an interrupt, and 1 enables an interrupt.
0	CD	R/W	0	Card detect (CD). A 0 masks an interrupt, and 1 enables an interrupt.

**Table 425. Command argument register (CMDARG, address 0x1800 0028)**

Bit	Symbol	Access	Reset value	Description
31:0	cmd_arg	R/W	0	Value indicates command argument to be passed to card.

**Table 426. Command register (CMD, address 0x1800 002C)**

Bit	Symbol	Access	Reset value	Description
31	start_cmd	R/W	0	Start command. Once command is taken by CIU, bit is cleared. When bit is set, cpu should not attempt to write to any command registers. If write is attempted, hardware lock error is set in raw interrupt register. Once command is sent and response is received from SD/MMC/CE-ATA cards, Command Done bit is set in raw interrupt register.
30:24	Reserved			
23	ccs_expected	R/W	0	0 – Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device 1 – Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device  If the command expects Command Completion Signal (CCS) from the CE-ATA device, the software should set this control bit. The module sets Data Transfer Over (DTO) bit in RINTSTS register and generates interrupt to cpu if Data Transfer Over interrupt is not masked.
22	read_ceata_device	R/W	0	0 – Cpu is not performing read access (RW_REG or RW_BLK) towards CE-ATA device 1 – Module is performing read access (RW_REG or RW_BLK) towards CE-ATA device  Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers. Maximum value of I/O transmission delay can be no less than 10 seconds. The module should not indicate read data timeout while waiting for data from CE-ATA device.

Table 426. Command register (CMD, address 0x1800 002C) ...continued

Bit	Symbol	Access	Reset value	Description
21	update_clock_registers_only	R/W	0	<p>0 – Normal command sequence</p> <p>1 – Do not send commands, just update clock register value into card clock domain following register values transferred into card clock domain: CLKDIV, CLRSRC, CLKENA.</p> <p>Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards.</p> <p>During normal command sequence, when update_clock_registers_only = 0, following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOU, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s).</p> <p>When bit is set, there are no Command Done interrupts because no command is sent to SD/MMC/CE-ATA cards.</p>
20:16	-	R/W	0	reserved
15	send_initialization	R/W	0	<p>0 – Do not send initialization sequence (80 clocks of 1) before sending this command.</p> <p>1 – Send initialization sequence before sending this command.</p> <p>After power on, 80 clocks must be sent to card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card.</p>
14	stop_abort_cmd	R/W	0	<p>0 – Neither stop nor abort command to stop current data transfer in progress. If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0.</p> <p>1 – Stop or abort command intended to stop current data transfer in progress.</p> <p>When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state.</p>
13	wait_prvdata_complete	R/W	0	<p>0 – Send command at once, even if previous data transfer has not completed.</p> <p>1 – Wait for previous data transfer completion before sending command.</p> <p>The wait_prvdata_complete = 0 option typically used to query status of card during data transfer or to stop current data transfer.</p>
12	send_auto_stop	R/W	0	<p>0 – No stop command sent at end of data transfer.</p> <p>1 – Send stop command at end of data transfer.</p> <p>Refer to <a href="#">Table 21-441</a> to determine:</p> <ul style="list-style-type: none"> <li>- when send_auto_stop bit should be set, since some data transfers do not need explicit stop commands.</li> <li>- open-ended transfers that software should explicitly send to stop command.</li> </ul> <p>Additionally, when “resume” is sent to resume – suspended memory access of SD-Combo card – bit should be set correctly if suspended data transfer needs send_auto_stop.</p> <p>Don't care if no data expected from card</p>

**Table 426. Command register (CMD, address 0x1800 002C) ...continued**

Bit	Symbol	Access	Reset value	Description
11	Transfer_mode	R/W	0	0 – Block data transfer command 1 – Stream data transfer command Don't care if no data expected.
10	Read/write	R/W	0	0 – Read from card. 1 – Write to card. Don't care if no data expected from card.
9	Data_transfer_exp ected	R/W	0	0 – No data transfer expected (read/write). 1 – Data transfer expected (read/write).
8	Check_response_c rc	R/W	0	0 – Do not check response CRC. 1 – Check response CRC. Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller
7	Response_length	R/W		0 – Short response expected from card 1 – Long response expected from card
6	Response_expect	R/W		0 – No response expected from card 1 – Response expected from card
5:0	Cmd_index	R/W	0	Command index

**Table 427. Response 0 register (RESPO, address 0x1800 0030)**

Bit	Name	Default	Description
31:0	response 0	0	Bit[31:0] of response

**Table 428. Response 1 register (RESP1, address 0x1800 0034)**

Bit	Name	Default	Description
31:0	response 1	0	Register represents bit[63:32] of long response. When CIU sends auto-stop command, then response is saved in this register. Response for previous command sent by module is still preserved in Response 0 register. Additional auto-stop issued only for data transfer commands, and response type is always "short" for them. For information on when CIU sends auto-stop commands, refer to "Functional description."

**Table 429. Response 2 register (RESP2, address 0x1800 0038)**

Bit	Name	Default	Description
31:0	response 2	0	Bit[95:64] of long response

**Table 430. Response 3 register (RESP3, address 0x1800 003C)**

Bit	Name	Default	Description
31:0	response 3	0	Bit[127:96] of long response

**Table 431. Masked interrupt status register (MINTSTS, address 0x1800 0040)**

Bits	Name	Access	Reset value	Description
31:17	-	-		Reserved
16	sdio_interrupt	R/W		Interrupt from SDIO card. SDIO interrupt for card enabled only if corresponding sdio_int_mask bit is set in Interrupt mask register (mask bit 1 enables interrupt; 0 masks interrupt). 0 – No SDIO interrupt from card 1 – SDIO interrupt from card
15	EBE	R/W	0	End-bit error (read)/Write no CRC (EBE).
14	ACD	R/W	0	Auto command done (ACD).
13	SBE	R/W	0	Start-bit error (SBE).
12	HLE	R/W	0	Hardware locked write error (HLE).
11	FRUN	R/W	0	FIFO underrun/overflow error (FRUN).
10	HTO	R/W	0	Data starvation-by-cpu timeout (HTO).
9	DRTO	R/W	0	Data read timeout (DRTO).
8	RTO	R/W	0	Response timeout (RTO).
7	DCRC	R/W	0	Data CRC error (DCRC).
6	RCRC	R/W	0	Response CRC error (RCRC).
5	RXDR	R/W	0	Receive FIFO data request (RXDR).
4	TXDR	R/W	0	Transmit FIFO data request (TXDR).
3	DTO	R/W	0	Data transfer over (DTO).
2	CD	R/W	0	Command done (CD).
1	RE	R/W	0	Response error (RE).
0	CD	R/W	0	Card detect (CD).

**Table 432. Raw interrupt status register (RINTSTS, address 0x1800 0044)**

Bit	Name	Access	Reset value	Description
31:17	-	-		Reserved
16	sdio_interrupt	R/W	0	Interrupt from SDIO card. Writes to these bits clear them. Writing a value of 1 clears bit and 0 leaves bit intact. 0 – No SDIO interrupt from card 1 – SDIO interrupt from card Bits are logged regardless of interrupt-mask status.
15	EBE	R/W	0	End-bit error (read)/Write no CRC (EBE). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
14	ACD	R/W	0	Auto command done (ACD). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
13	SBE	R/W	0	Start-bit error (SBE). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
12	HLE	R/W	0	Hardware locked write error (HLE). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.

Table 432. Raw interrupt status register (RINTSTS, address 0x1800 0044)

Bit	Name	Access		Description
11	FRUN	R/W	0	FIFO underrun/overflow error (FRUN). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
10	HTO	R/W	0	Data starvation-by-cpu timeout (HTO). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
9	DRTO	R/W	0	Data read timeout (DRTO). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
8	RTO	R/W	0	Response timeout (RTO). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
7	DCRC	R/W	0	Data CRC error (DCRC). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
6	RCRC	R/W	0	Response CRC error (RCRC). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
5	RXDR	R/W	0	Receive FIFO data request (RXDR). Value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
4	TXDR	R/W	0	Transmit FIFO data request (TXDR). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
3	DTO	R/W	0	Data transfer over (DTO). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
2	CD	R/W	0	Command done (CD). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
1	RE	R/W	0	Response error (RE). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.
0	CD	R/W	0	Card detect (CD). Writing a value of 1 clears status bit, and value of 0 leaves bit intact. Bits are logged regardless of interrupt mask status.

Table 433. Status register (STATUS, address 0x1800 0048)

Bit	Name	Default	Description
31	Dma_req	0	DMA request signal state
30	dma_ack	0	DMA acknowledge signal state
29:17	fifo_count	0	FIFO count – Number of filled locations in FIFO
16:11	response_index	0	Index of previous response, including any auto-stop sent by core
10	data_state_mc_busy	0	Data transmit or receive state-machine is busy
9	data_busy	1 or 0;	Inverted version of MCI_DATA_0 pin 0 – card data not busy 1 – card data busy
8	data_3_status	1 or 0;	Raw state of MCI_DATA_3 pin; checks whether card is present 0 – card not present 1 – card present
7:4	command_fsm_states	0	Command FSM states: 0 – Idle 1 – Send init sequence 2 – Tx cmd start bit 3 – Tx cmd tx bit 4 – Tx cmd index + arg 5 – Tx cmd crc7 6 – Tx cmd end bit 7 – Rx resp start bit 8 – Rx resp IRQ response 9 – Rx resp tx bit 10 – Rx resp cmd idx 11 – Rx resp data 12 – Rx resp crc7 13 – Rx resp end bit 14 – Cmd path wait NCC 15 – Wait; CMD-to-response turnaround
3	fifo_full	0	FIFO is full status
2	fifo_empty	1	FIFO is empty status
1	fifo_tx_watermark	1	FIFO reached Transmit watermark level; not qualified with data transfer.
0	fifo_rx_watermark	0	FIFO reached Receive watermark level; not qualified with data transfer.

Table 434. FIFO threshold register, bits 31:28 (FIFOTH, address 0x1800 004C)

Bit	Name	Default	Description

Bit	Name	Default	Description
27:16	RX_WMark	0x1F (= FIFO_DEPTH-1)	<p>FIFO threshold watermark level when receiving data to card.</p> <p>When FIFO data count reaches greater than this number, DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data.</p> <p>In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of cpu to read remaining bytes on seeing Data Transfer Done interrupt.</p> <p>In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set.</p> <p>12 bits – 1 bit less than FIFO-count of status register, which is 13 bits.</p> <p>Limitation: <math>RX\_WMark \leq FIFO\_DEPTH-2</math>  Recommended: <math>(FIFO\_DEPTH/2) - 1</math>; (means greater than <math>(FIFO\_DEPTH/2) - 1</math>)</p>

**Table 436. FIFO threshold register, bits 15:0 (FIFOTH, address 0x1800 004C)**

Bit	Name	Default	Description
15:12	-	-	Reserved
11:0	TX_WMark	0	<p>FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number, DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated, regardless of threshold programming.</p> <p>In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, cpu is responsible for filling FIFO with only required remaining bytes (not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty).</p> <p>In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred.</p> <p>12 bits – 1 bit less than FIFO-count of status register, which is 13 bits.</p> <p>Limitation: TX_WMark &gt;= 1; Recommended: FIFO_DEPTH/2; (means less than or equal to FIFO_DEPTH/2)</p>

**Table 437. Card detect register (CDETECT, address 0x1800 0050)**

Bits	Name	Default	Description
31:1	-	-	Reserved
0	Card_detect_n	0	0 represents presence of card. This bit is influenced by setting the BIT[1] in SYSCREG_SD_MMC_CFG configuration register in SYSCREG module.

**Table 438. Write protect register (WRTPRT, address 0x1800 0054)**

Bits	Name	Default	Description
31:1	-	-	Reserved
0	Write_protect	0	1 represents write protection. This bit is influenced by setting the BIT[0] in SYSCREG_SD_MMC_CFG configuration register in SYSCREG module.

**Table 439. Transferred CIU card byte count (TCBINT, address 0x1800 005C)**

Bits	Name	Default	Description
31:0	Trans_card_byte_count	0	Number of bytes transferred by CIU unit to card.

The register should be read only after data transfer completes; during data transfer, register returns 0.

**Table 440. Transferred cpu/DMA to/from BIU-FIFO byte count (TBBINT, address 0x1800 0060)**

Bits	Name	Default	Description
31:0	Trans_fifo_byte_count	0	Number of bytes transferred between AHB/DMA memory and BIU FIFO.

## 5. Functional description

### 5.1 Auto-Stop

The auto-stop command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for SD memory transfer for SD cards. The module internally generates a stop command and is loaded in the command path when the send\_auto\_stop bit is set in the Command register.

The software should set the send\_auto\_stop bit according to details listed in table below:

**Table 441. send\_auto\_stop bit**

Card Type	Transfer Type	Byte Count	send_auto_stop bit set	Comments
MMC	Stream read	0	No	Open-ended stream
MMC	Stream read	>0	Yes	Auto-stop after all bytes transfer
MMC	Stream read	0	No	Open-ended stream
MMC	Stream read	>0	Yes	Auto-stop after all bytes transfer
MMC	Single-block read	>0	No	Byte count = 0 is illegal
MMC	Single-block write	>0	No	Byte count = 0 is illegal
MMC	Multiple-block read	0	No	Open-ended multiple block
MMC	Multiple-block read	>0	Yes <sup>[1]</sup>	Pre-defined multiple block
MMC	Multiple-block write	0	No	Open-ended multiple block
MMC	Multiple-block write	>0	Yes <sup>[1]</sup>	Pre-defined multiple block

Table 441. send\_auto\_stop bit

Card Type	Transfer Type	Byte Count	send_auto_stop bit set	Comments
SDMEM	Single-block read	>0	No	Byte count = 0 is illegal
SDMEM	Single-block write	>0	No	Byte count = 0 is illegal
SDMEM	Multiple-block read	0	No	Open-ended multiple block
SDMEM	Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
SDMEM	Multiple-block write	0	No	Open-ended multiple block
SDMEM	Multiple-block write	>0	Yes	Auto-stop after all bytes transfer
SDIO	Single-block read	>0	No	Byte count = 0 is illegal
SDIO	Single-block write	>0	No	Byte count = 0 is illegal
SDIO	Multiple-block read	0	No	Open-ended multiple block
SDIO	Multiple-block read	>0	No	Pre-defined multiple block
SDIO	Multiple-block write	0	No	Open-ended multiple block
SDIO	Multiple-block write	>0	No	Pre-defined multiple block

- [1] The condition under which the transfer mode is set to block transfer and byte\_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte\_count = n × block\_size (n = 2, 3, ...), the condition is treated as a predefined multiple-block data transfer command. In the case of an MMC card, the cpu software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the send\_auto\_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send\_auto\_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.

The following list conditions for the auto-stop command.

- Stream read for MMC card with byte count greater than 0 - The Module generates an internal stop command and loads it into the command path so that the end bit of the stop command is sent out when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than 6 (48 bits), a few extra data bytes are received from the card before the end bit of the stop command is sent.
- Stream write for MMC card with byte count greater than 0 - The Module generates an internal stop command and loads it into the command path so that the end bit of the stop command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than 6 (48 bits), the data path transmits the data last in order to meet the above condition.

- Multiple-block read memory for SD card with byte count greater than 0 - If the block size is less than 4 (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the auto-stop command is loaded in the command path after all the bytes are read. Otherwise, the top command is loaded in the command path so that the end bit of the stop command is sent after the last data block is received.
- Multiple-block write memory for SD card with byte count greater than 0 - If the block size is less than 3 (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the auto-stop command is loaded in the command path after all data blocks are transmitted. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the end bit of the CRC status is received.
- Precaution for cpu software during auto-stop - Whenever an auto-stop command is issued, the cpu software should not issue a new command to the Module until the auto-stop is sent by the Module and the data transfer is complete. If the cpu issues a new command during a data transfer with the auto-stop in progress, an auto-stop command may be sent after the new command is sent and its response is received; this can delay sending the stop command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the cpu wants to terminate the data transfer before the data transfer is complete, it can issue a stop or abort command, in which case the Module does not generate an auto-stop command.

## 6. Power optimization

---

Not applicable.

## 7. Programming guide

---

### 7.1 Software/hardware restrictions

Only one data transfer command should be issued at one time. For CE-ATA devices, if CE-ATA device interrupts are enabled ( $nIEN=0$ ), only one `RW_MULTIPLE_BLOCK` command (`RW_BLK`) should be issued; no other commands (including a new `RW_BLK`) should be issued before the Data Transfer. Over status is set for the outstanding `RW_BLK`.

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.

To avoid glitches in the card clock outputs (`cclk_out`), the software should use the following steps when changing the card clock frequency:

1. Update the Clock Enable register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:
  - `start_cmd` bit
  - "update clock registers only" bits
  - "wait\_previous data complete" bit

Wait for the CIU to take the command by polling for 0 on the start\_cmd bit.

2. Set the start\_cmd bit to update the Clock Divider and/or Clock Source registers, and send a command to the CIU in order to update the clock registers; wait for the CIU to take the command.
3. Set start\_cmd to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.

In non-DMA mode, while reading from a card, the Data Transfer Over (RINTSTS[3]) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the RX\_WMark interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. In DMA mode while reading from a card, the DTO interrupt occurs only after all the FIFO data is flushed to memory by the DMA Interface unit.

While writing to a card in DMA mode, if an undefined-length transfer is selected by setting the Byte Count register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.

If the software issues a controller\_reset command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the cpu. In addition to a card-reset, if a FIFO reset is also issued, then:

- Any pending DMA transfer on the bus completes correctly
- DMA data read is ignored
- Write data is unknown (x)

Additionally, if dma\_reset is also issued, any pending DMA transfer is abruptly terminated. The DMA controller channel should also be reset and reprogrammed.

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.

One data-transfer requirement between the FIFO and cpu is that the number of transfers should be a multiple of the FIFO data width (F\_DATA\_WIDTH), which is 32. So if you want to write only 15 bytes to an SD/MMC/CE-ATA card (BYTCNT), the cpu should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers, if DMA mode is enabled. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the cpu should still read all 16 bytes from the FIFO.

It is recommended that you do not change the FIFO threshold register in the middle of data transfers.

## 7.2 Programming sequence

### 7.2.1 Initialization

Once the power and clocks are stable, reset\_n should be asserted (active-low) for at least two clocks of clk or cclk\_in, whichever is slower. The reset initializes the registers, ports, FIFO-pointers, DMA interface controls, and state-machines in the design. After power-on reset, the software should do the following:

1. After power on reset SD/MMC pins (mGPIO5 -mGPIO9) on this chip are configured as GPIO input pins. So set SYS\_MUX\_GPIO\_MCI (0x13002894) to 1 and also update IOCONF EBI\_MCI registers to change mGPIO5-mGPIO9 pins from inputs to 'driven by IP' state.
2. Set masks for interrupts by clearing appropriate bits in the Interrupt Mask register @0x024. Set the global int\_enable bit of the Control register @0x00. It is recommended that you write 0xffff\_fff to the Raw Interrupt register @0x044 in order to clear any pending interrupts before setting the int\_enable bit.
3. Enumerate card stack - Each card is enumerated according to card type; for details, refer to "Enumerated Card Stack". For enumeration, you should restrict the clock frequency to 400 KHz in accordance with SD\_MMC/CE-ATA standards.
4. Changing clock. The cards operate at a maximum of 26 MHz (at maximum of 52 MHz in high-speed mode).
5. Set other IP parameters, which normally do not need to be changed with every command, with a typical value such as timeout values in cclk\_out according to SD\_MMC/CE-ATA specifications.

ResponseTimeOut = 0x40

DataTimeOut = highest of one of the following:

- $(10 \times ((TAAC \times Fop) + (100 \times NSAC)))$
- Cpu FIFO read/write latency from FIFO empty/full

FIFO threshold value in bytes in the FIFOTH register @0x04C. Typically, the threshold value can be set to half the FIFO depth (=32); that is:

- $RX\_WMark = (FIFO\_DEPTH/2) - 1;$
- $TX\_WMark = FIFO\_DEPTH/2$

6. If the software decides to handle the interrupts provided by the IP core, you should create another thread to handle interrupts.

### 7.2.2 Enumerated Card Stack

The card stack does the following:

- Enumerates all connected cards
- Sets the RCA for the connected cards
- Reads card-specific information
- Stores card-specific information locally

Enumerate\_Card\_Stack - Enumerates the card connected on the module. The card can be of the type MMC, CE-ATA, SD, or SDIO. All types of SDIO cards are supported; that is, SDIO\_IO\_ONLY, SDIO\_MEM\_ONLY, and SDIO\_COMBO cards. The enumeration sequence includes the following steps:

1. Check if the card is connected.
2. Clear the bits in the card\_type register. Clear the register bit for a 1-bit, 4-bit, or 8-bit bus width.
3. Identify the card type; that is, SD, MMC, or SDIO.
  - Send CMD5 first. If a response is received, then the card is SDIO
  - If not, send ACMD41; if a response is received, then the card is SD.
  - Otherwise, the card is an MMC or CE-ATA
4. Enumerate the card according to the card type.
 

Use a clock source with a frequency = Fod (that is, 400 KHz) and use the following enumeration command sequence:

  - SD card - Send CMD0, ACMD41, CMD2, CMD3.
  - SDHC card - send CMD0, SDCMD8, ACMD41, CMD2, CMD3
  - SDIO - Send CMD5; if the function count is valid, CMD3. For the SDIO memory section, follow the same commands as for the SD card.
  - MMC - Send CMD0, CMD1, CMD2, CMD3
5. Identify the MMC/CE-ATA device.
  - Selecting ATA mode for a CE-ATA device.
  - Cpu should query the byte 504 (S\_CMD\_SET) of EXT\_CSD register by sending CMD8. If bit 4 is set to "1," then the device supports ATA mode.
  - If ATA mode is supported, the cpu should select the ATA mode by setting the ATA bit (bit 4) of the EXT\_CSD register slice 191(CMD\_SET) to activate the ATA command set for use. The cpu selects the command set using the SWITCH (CMD6) command.
  - The current mode selected is shown in byte 191 of the EXT\_CSD register.
 

If the device does not support ATA mode, then the device can be an MMC device or a CE-ATA v1.0 device.
  - Send RW\_REG; if a response is received and the response data contains CE-ATA signature, the device is a CE-ATA device.
  - Otherwise the device is an MMC card.
6. You can change the card clock frequency after enumeration.

### 7.2.3 Clock Programming

The clock programming has to be done in the CGU. The cclk\_in has to be equal to the cclk\_out. Therefore the registers that support this have to be:

- CLKDIV @0x08 = 0x0 (bypass of clock divider).
- CLKSRC @0x0C = 0x0
- CLKENA @0x10 = 0x0 or 0x1. This register enables or disables clock for the card and enables low-power mode, which automatically stops the clock to a card when the card is idle for more than 8 clocks.

The Module loads each of these registers only when the `start_cmd` bit and the `Update_clk_regs_only` bit in the CMD register are set. When a command is successfully loaded, the Module clears this bit, unless the Module already has another command in the queue, at which point it gives an HLE (Hardware Locked Error); for details on HLEs, refer to "Error Handling".

Software should look for the `start_cmd` and the `Update_clk_regs_only` bits, and should also set the `wait_prvdata_complete` bit to ensure that clock parameters do not change during data transfer. Note that even though `start_cmd` is set for updating clock registers, the Module does not raise a `command_done` signal upon command completion.

### 7.2.4 No-Data Command With or Without Response Sequence

To send any non-data command, the software needs to program the CMD register @0x2C and the CMDARG register @0x28 with appropriate parameters. Using these two registers, the Module forms the command and sends it to the command bus. The Module reflects the errors in the command response through the error bits of the RINTSTS register.

When a response is received - either erroneous or valid - the Module sets the `command_done` bit in the RINTSTS register. A short response is copied in Response Register0, while a long response is copied to all four response registers @0x30, 0x34, 0x38, and 0x3C. The Response3 register bit 31 represents the MSB, and the Response0 register bit 0 represents the LSB of a long response.

For basic commands or non-data commands, follow these steps:

1. Program the Command register @0x28 with the appropriate command argument parameter.
2. Program the Command register @0x2C with the settings in [Table 21-442](#).
3. Wait for command acceptance by cpu. The following happens when the command is loaded into the Module:
  - Module accepts the command for execution and clears the `start_cmd` bit in the CMD register, unless one command is in process, at which point the Module can load and keep the second command in the buffer.
  - If the Module is unable to load the command - that is, a command is already in progress, a second command is in the buffer, and a third command is attempted - then it generates an HLE (hardware-locked error).
  - Check if there is an HLE.
  - Wait for command execution to complete. After receiving either a response from a card or response timeout, the Module sets the `command_done` bit in the RINTSTS register. Software can either poll for this bit or respond to a generated interrupt.
  - Check if `response_timeout` error, `response_CRC` error, or `response error` is set. This can be done either by responding to an interrupt raised by these errors or by polling bits 1, 6, and 8 from the RINTSTS register @0x44. If no response error is received, then the response is valid. If required, the software can copy the response from the response registers @0x30-0x3C.

Software should not modify clock parameters while a command is being executed.

Table 442. CMD register settings for No-Data Command

Name	Value	Comment
start_cmd	1	
update_clock_registers_only	0	No clock parameters update command
card_number	0	Card number in use. Only zero is possible because one card is support.
Data_expected	0	No data command.
Send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
Cmd_index	Command index	
Response_length	0	Can be 1 for R2 (long) response
Response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
Wait_prvdata_complete	1	Before sending command on command line, cpu should wait for completion of any data command in process, if any (recommended to always set this bit, unless the current command is to query status or stop data transfer when transfer is in progress)
Check_response_crc	1	0 – Do not check response CRC 1 – Check response CRC  Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.

### 7.2.5 Data Transfer Commands

Data transfer commands transfer data between the memory card and the Module. To send a data command, the Module needs a command argument, total data size, and block size. Software can receive or send data through the FIFO.

Before a data transfer command, software should confirm that the card is not busy and is in a transfer state, which can be done using the CMD13 and CMD7 commands, respectively.

For the data transfer commands, it is important that the same bus width that is programmed in the card should be set in the card type register @0x18. Therefore, in order to change the bus width, you should always use the following supplied APIs as appropriate for the type of card:

- Set\_SD\_Mode() - SD/SDIO card
- Set\_HSmodeSettings() - HSMCMC card

The Module generates an interrupt for different conditions during data transfer, which are reflected in the RINTSTS register @0x44 as:

1. Data\_Transfer\_Over (bit 3) - When data transfer is over or terminated. If there is a response timeout error, then the Module does not attempt any data transfer and the "Data Transfer Over" bit is never set.
2. Transmit\_FIFO\_Data\_request (bit 4) - FIFO threshold for transmitting data was reached; software is expected to write data, if available, in FIFO.
3. Receive\_FIFO\_Data\_request (bit 5) - FIFO threshold for receiving data was reached; software is expected to read data from FIFO.
4. Data starvation by Cpu timeout (bit 10) - FIFO is empty during transmission or is full during reception. Unless software writes data for empty condition or reads data for full condition, the Module cannot continue with data transfer. The clock to the card has been stopped.
5. Data read timeout error (bit 9) - Card has not sent data within the timeout period.
6. Data CRC error (bit 7) - CRC error occurred during data reception.
7. Start bit error (bit 13) - Start bit was not received during data reception.
8. End bit error (bit 15) - End bit was not received during data reception or for a write operation; a CRC error is indicated by the card.

Conditions 6, 7, and 8 indicate that the received data may have errors. If there was a response timeout, then no data transfer occurred.

### 7.2.6 Single-Block or Multiple-Block Read

Steps involved in a single-block or multiple-block read are:

1. Write the data size in bytes in the BYTCNT register @0x20.
2. Write the block size in bytes in the BLKSIZ register @0x1C. The Module expects data from the card in blocks of size BLKSIZ each.
3. Program the CMDARG register @0x28 with the data address of the beginning of a data read. Program the Command register with the parameters listed in [Table 21-443](#). For SD and MMC cards, use CMD17 for a single-block read and CMD18 for a multiple-block read. For SDIO cards, use CMD53 for both single-block and multiple-block transfers.

After writing to the CMD register, the Module starts executing the command; when the command is sent to the bus, the command\_done interrupt is generated.

4. Software should look for data error interrupts; that is, bits 7, 9, 13, and 15 of the RINTSTS register. If required, software can terminate the data transfer by sending a STOP command.
5. Software should look for Receive\_FIFO\_Data\_request and/or data starvation by cpu timeout conditions. In both cases, the software should read data from the FIFO and make space in the FIFO for receiving more data.
6. When a Data\_Transfer\_Over interrupt is received, the software should read the remaining data from the FIFO.

**Table 443. CMD register settings for Single-block or Multiple-block Read**

Name	Value	Comment
start_cmd	1	
update_clock_registers_only	0	No clock parameters update command
card_number	0	Card number in use. Only zero is possible because one card is support.
Data_expected	1	
Send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
Send_auto_stop	0/1	Set according to <tb>
Transfer_mode	0	Block transfer
Read_write	0	Read from card
Cmd_index	Command index	
Response_length	0	Can be 1 for R2 (long) response
Response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
Wait_prvdata_complete	1	Before sending command on command line, cpu should wait for completion of any data command in process, if any (recommended to always set this bit, unless the current command is to query status or stop data transfer when transfer is in progress)
Check_response_crc	1	0 – Do not check response CRC 1 – Check response CRC Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.

### 7.2.7 Single-Block or Multiple-Block Write

Steps involved in a single-block or multiple-block write are:

1. Write the data size in bytes in the BYTCNT register @0x20.
2. Write the block size in bytes in the BLKSIZ register @0x1C; the Module sends data in blocks of size BLKSIZ each.
3. Program CMDARG register @0x28 with the data address to which data should be written.
4. Write data in the FIFO; it is usually best to start filling data the full depth of the FIFO.

5. Program the Command register with the parameters listed in [Table 21–444](#). For SD and MMC cards, use CMD24 for a single-block write and CMD25 for a multiple-block write. For SDIO cards, use CMD53 for both single-block and multiple-block transfers. After writing to the CMD register, Module starts executing a command; when the command is sent to the bus, a command\_done interrupt is generated.
6. Software should look for data error interrupts; that is, for bits 7, 9, and 15 of the RINTSTS register. If required, software can terminate the data transfer by sending the STOP command.
7. Software should look for Transmit\_FIFO\_Data\_request and/or timeout conditions from data starvation by the cpu. In both cases, the software should write data into the FIFO.
8. When a Data\_Transfer\_Over interrupt is received, the data command is over. For an open-ended block transfer, if the byte count is 0, the software must send the STOP command. If the byte count is not 0, then upon completion of a transfer of a given number of bytes, the Module should send the STOP command, if necessary. Completion of the AUTO-STOP command is reflected by the Auto\_command\_done interrupt - bit 14 of the RINTSTS register. A response to AUTO\_STOP is stored in RESP1 @0x34.

**Table 444. CMD register settings for Single-block or Multiple-block write**

Name	Value	Comments
start_cmd	1	
update_clock_registers_only	0	No clock parameters update command
card_number	0	Card number in use. Only zero is possible because one card is support.
Data_expected	1	
Send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
Send_auto_stop	0/1	Set according to XXXXXXXXXX
Transfer_mode	0	Block transfer
Read_write	1	Write to card
Cmd_index	Command index	
Response_length	0	Can be 1 for R2 (long) response
Response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on

Table 444. CMD register settings for Single-block or Multiple-block write

Name	Value	Comments
User-selectable		
Wait_prvdata_complete	1	Before sending command on command line, cpu should wait for completion of any data command in process, if any (recommended to always set this bit, unless the current command is to query status or stop data transfer when transfer is in progress)
Check_response_crc	1	0 – Do not check response CRC 1 – Check response CRC Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.

### 7.2.8 Stream Read

A stream read is like the block read mentioned in "Single-Block or Multiple-Block Read", except for the following bits in the Command register:

```
transfer_mode = 1; //Stream transfer
```

```
cmd_index = CMD20;
```

A stream transfer is allowed for only a single-bit bus width.

### 7.2.9 Stream Write

A stream write is exactly like the block write mentioned in "Single-Block or Multiple-Block Write", except for the following bits in the Command register:

- transfer\_mode = 1; //Stream transfer
- cmd\_index = CMD11;

In a stream transfer, if the byte count is 0, then the software must send the STOP command. If the byte count is not 0, then when a given number of bytes completes a transfer, the Module sends the STOP command. Completion of this AUTO\_STOP command is reflected by the Auto\_command\_done interrupt. A response to an AUTO\_STOP is stored in the RESP1 register @0x34.

A stream transfer is allowed for only a single-bit bus width.

### 7.2.10 Sending Stop or Abort in Middle of Transfer

The STOP command can terminate a data transfer between a memory card and the Module, while the ABORT command can terminate an I/O data transfer for only the SDIO\_IOONLY and SDIO\_COMBO cards.

- Send STOP command - Can be sent on the command line while a data transfer is in progress; this command can be sent at any time during a data transfer. For information on sending this command, refer to "No-Data Command With or Without Response Sequence".

You can also use an additional setting for this command in order to set the Command register bits (5-0) to CMD12 and set bit 14 (stop\_abort\_cmd) to 1. If stop\_abort\_cmd is not set to 1, the user stopped a data transfer. Reset bit 13 of the Command register (wait\_prvdata\_complete) to 0 in order to make the Module send the command at once, even though there is a data transfer in progress.

- Send ABORT command - Can be used with only an SDIO\_IOONLY or SDIO\_COMBO card. To abort the function that is transferring data, program the function number in ASx bits (CCCR register of card, address 0x06, bits (0-2) using CMD52.

This is a non-data command. For information on sending this command, refer to "No-Data Command With or Without Response Sequence".

Program the CMDARG register @0x28 with the appropriate command argument parameters listed in [Table 21-445](#).

- Program the Command register using the command index as CMD52. Similar to the STOPcommand, set bit 14 of the Command register (stop\_abort\_cmd) to 1, which must be done in order to inform the Module that the user aborted the data transfer. Reset bit 13 (wait\_prvdata\_complete) of the Command register to 0 in order to make the Module send the command at once, even though a data transfer is in progress.
- Wait for command\_transfer\_over.
- Check response (R5) for errors.
- During an open-ended card write operation, if the card clock is stopped because the FIFO is empty, the software must first fill the data into the FIFO and start the card clock before issuing a stop/abort command to the card.

**Table 445. Parameters for CMDARG register**

Bits	Contents	Value
31	R/W flag	1
30-28	Function number	0, for CCCR access
27	RAW flag	1, if needed to read after write
26	Don't care	-
25-9	Register address	0x06
8	Don't care	-
7-0	Write data	Function number to be aborted

### 7.3 Suspend or Resume Sequence

In an SDIO card, the data transfer between an I/O function and the Module can be temporarily halted using the SUSPEND command; this may be required in order to perform a high-priority data transfer with another function. When desired, the data transfer can be resumed using the RESUME command.

The following functions can be implemented by programming the appropriate bits in the CCCR register (Function 0) of the SDIO card. To read from or write to the CCCR register, use the CMD52 command.

1. SUSPEND data transfer - Non-data command.

- Check if the SDIO card supports the SUSPEND/RESUME protocol; this can be done through the SBS bit in the CCCR register @0x08 of the card.

Check if the data transfer for the required function number is in process; the function number that is currently active is reflected in bits 0-3 of the CCCR register @0x0D. Note that if the BS bit (address 0xc::bit 0) is 1, then only the function number given by the FSx bits is valid.

To suspend the transfer, set BR (bit 2) of the CCCR register @0x0C.

Poll for clear status of bits BR (bit 1) and BS (bit 0) of the CCCR @0x0C. The BS (Bus Status) bit is 1 when the currently-selected function is using the data bus; the BR (Bus Release) bit remains 1 until the bus release is complete. When the BR and BS bits are 0, the data transfer from the selected function has been suspended.

During a read-data transfer, the Module can be waiting for the data from the card. If the data transfer is a read from a card, then the Module must be informed after the successful completion of the SUSPEND command. The Module then resets the data state machine and comes out of the wait state. To accomplish this, set `abort_read_data` (bit 8) in the Control register.

Wait for data completion. Get pending bytes to transfer by reading the TCBCNT register @0x5C.

2. RESUME data transfer - This is a data command.

- Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.

If the card is in a disconnect state, select it using CMD7. The card status can be retrieved in response to CMD52/CMD53 commands.

Check that a function to be resumed is ready for data transfer; this can be confirmed by reading the RFx flag in CCCR @0x0F. If RF = 1, then the function is ready for data transfer.

To resume transfer, use CMD52 to write the function number at FSx bits (0-3) in the CCCR register @0x0D. Form the command argument for CMD52 and write it in CMDARG @0x28; bit values are listed in [Table 21–446](#).

- Write the block size in the BLKSIZ register @0x1C; data will be transferred in units of this block size.

Write the byte count in the BYTCNT register @0x20. This is the total size of the data; that is, the remaining bytes to be transferred. It is the responsibility of the software to handle the data.

Program Command register; similar to a block transfer. For details, refer to "Single-Block or Multiple-Block Read" and "Single-Block or Multiple-Block Write".

When the Command register is programmed, the command is sent and the function resumes data transfer. Read the DF flag (Resume Data Flag). If it is 1, then the function has data for the transfer and will begin a data transfer as soon as the function or memory is resumed. If it is 0, then the function has no data for the transfer.

If the DF flag is 0, then in case of a read, the Module waits for data. After the data timeout period, it gives a data timeout error.

**Table 446. Parameters for CMDARG register**

Bits	Contents	Value
31	R/W flag	1
30-28	Function number	0, for CCCR access
27	RAW flag	1, read after write
26	Don't care	-
25-9	Register address	0x0D
8	Don't care	-
7-0	Write data	Function number to be aborted

### 7.3.1 Read\_Wait Sequence

Read\_wait is used with only the SDIO card and can temporarily stall the data transfer-either from function or memory-and allow the cpu to send commands to any function within the SDIO device. The cpu can stall this transfer for as long as required. The Module provides the facility to signal this stall transfer to the card. The steps for doing this are:

1. Check if the card supports the read\_wait facility; read SRW (bit 2) of the CCCR register @0x08. If this bit is 1, then all functions in the card support the read\_wait facility. Use CMD52 to read this bit.
2. If the card supports the read\_wait signal, then assert it by setting the read\_wait (bit 6) in the CTRL register @0x00.
3. Clear the read\_wait bit in the CTRL register.

### 7.3.2 CE-ATA Data Transfer Commands

This section describes the CE-ATA data transfer commands. For information on the basic settings and interrupts generated for different conditions, refer to "Data Transfer Commands".

#### 7.3.2.1 Reset and Device Recovery

Before starting CE-ATA operations, the cpu should perform an MMC reset and initialization procedure. The cpu and device should negotiate the MMC TRAN state (defined by the MultiMedia Card System Specification) before the device enters the MMC TRAN state. The cpu should follow the existing MMC Card enumeration procedure in order to negotiate the MMC TRAN state. After completing normal MMC reset and initialization procedures, the cpu should query the initial ATA Task File values using RW\_REG/CMD39.

By default, the MMC block size is 512 bytes-indicated by bits 1:0 of the srcControl register inside the CE-ATA device. The cpu can negotiate the use of a 1KB or 4KB MMC block size. The device indicates MMC block sizes that it can support through the srcCapabilities register; the cpu reads this register in order to negotiate the MMC block size. Negotiation is complete when the cpu controller writes the MMC block size into the srcControl register bits 1:0 of the device.

### 7.3.2.2 ATA Task File Transfer

ATA task file registers are mapped to addresses 0x00h-0x10h in the MMC register space. RW\_REG is used to issue the ATA command, and the ATA task file is transmitted in a single RW\_REG MMC command sequence.

The cpu software stack should write the task file image to the FIFO before setting the CMDARG and CMD registers. The cpu processor then sets the address and byte count in the CMDARG-offset 0x28 in the BIU register space-before setting the CMD (offset 0x2C) register bits.

For RW\_REG, there is no command completion signal from the CE-ATA device

#### ATA Task File Transfer Using RW\_MULTIPLE\_REGISTER (RW\_REG)

This command involves data transfer between the CE-ATA device and the Module. To send a data command, the Module needs a command argument, total data size, and block size. Software can receive or send data through the FIFO.

Steps involved in an ATA Task file transfer (read or write) are:

1. Write the data size in bytes in the BYTCNT register @0x20.
2. Write the block size in bytes in the BLKSIZ register @0x1C; the Module expects a single block transfer.
3. Program the CMDARG register @0x28 with the beginning register address.

You should program the CMDARG, CMD, BLKSIZ, and BYTCNT registers according to the following tables.

- Program the Command Argument (CMDARG) register as shown below.

**Table 447. Parameters for CMDARG register**

Bits	Contents	Value
31	R/W flag	1 (write) or 0 (read)
30-24	Reserved	0
23:18	Starting register address for read/write; Dword aligned	0
17:16	Register address; Dword aligned	0
15-8	Reserved; bits cleared to 0 by CPU	0
7:2	Number of bytes to read/write; integral number of Dwords	16
1:0	Byte count in integral number of Dwords	0

- Program the Command (CMD) register as shown below.

Table 448. CMD register settings

Name	Value	Comment
start_cmd	1	
Css_expect	0	Command Completion Signal is not expected
Read_ceata_device	0/1	1 – If RW_BLK or RW_REG read
update_clock_registers_only	0	No clock parameters update command
card_number	0	Card number in use. Only zero is possible because one card is support.
Data_expected	1	
Send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	
Send_auto_stop	0	
Transfer_mode	0	Block transfer
Read_write	0/1	0 read from card, 1 - Write to card
Cmd_index	Command index	
Response_length	0	
Response_expect	1	
User-selectable		
Wait_prvdata_complete	1	0 – Sends command immediately 1 – Sends command after previous data transfer over
Check_response_crc	1	0 – Do not check response CRC 1 – Check response CRC

- Program the block size (BLKSIZ) register as shown below.

Table 449. BLKSIZ register

Bits	Value	Comment
31:16	0	Reserved bits as zeroes (0)
15:0	16	For accessing entire task file (16, 8-bit registers); block size of 16 bytes

- Program the Byte Count (BYTCNT) register as shown below.

Table 450. BYTCNT register

Bits	Value	Comment
31:0	16	For accessing entire task file(16, 8 bit registers); byte count value of 16 is used with the block size set to 16

### 7.3.2.3 ATA Payload Transfer Using RW\_MULTIPLE\_BLOCK (RW\_BLK)

This command involves data transfer between the CE-ATA device and the Module. To send a data command, the Module needs a command argument, total data size, and block size. Software can receive or send data through the FIFO.

Steps involved in an ATA payload transfer (read or write) are:

1. Write the data size in bytes in the BYTCNT register @0x20.
2. Write the block size in bytes in the BLKSIZ register @0x1C. The Module expects a single/multiple block transfer.
3. Program the CMDARG register @0x28 to indicate the Data Unit Count.  
 You should program the CMDARG, CMD, BLKSIZ, and BYTCNT registers according to the following tables.
  - Program the Command Argument (CMDARG) register as shown below.

**Table 451. Parameters for CMDARG register**

Bits	Contents	Value
31	R/W flag	1 (write) or 0 (read)
30-24	Reserved	0
23:16	Reserved	0
15:8	Data Count Unit [15:8]	Data count
1:0	Data Count Unit [7:0]	Data count

- Program the Command (CMD) register as shown below.

**Table 452. CMD register settings**

Name	Value	Comment
start_cmd	1	-
Css_expect	1	Command Completion Signal is expected; set for RW_BLK if interrupts are enabled in CE-ATA device, nIEN = 0
Read_ceata_device	0/1	1 – If RW_BLK or RW_REG read
update_clock_registers_only	0	No clock parameters update command
card_number	0	Card number in use. Only zero is possible because one card is support.
Data_expected	1	
Send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	
Send_auto_stop	0	
Transfer_mode	0	Block transfer
Read_write	0/1	0 read from card, 1 - Write to card
Cmd_index	Command index	
Response_length	0	
Response_expect	1	
User-selectable		
Wait_prvdata_complete	1	0 – Sends command immediately 1 – Sends command after previous data transfer over
Check_response_crc	1	0 – Do not check response CRC 1 – Check response CRC

- Program the block size (BLKSIZ) register as shown below.

**Table 453. BLKSIZ register**

Bits	Value	Comment
31:16	0	Reserved bits as zeroes (0)
15:0	512, 1024, 4096	MMC block size can be 512, 1024, or 4096 bytes as negotiated by CPU

- Program the Byte Count (BYTCNT) register as shown below.

**Table 454. BYTCNT register**

Bits	Value	Comment
31:0	$N \times \text{block\_size}$	byte_count should be integral multiple of block size; for ATA media access commands, byte count should be multiple of 4KB. ( $N \times \text{block\_size} = X \times 4\text{KB}$ , where N and X are integers)

#### 7.3.2.4 Sending Command Completion Signal Disable

While waiting for the Command Completion Signal (CCS) for an outstanding RW\_BLK, the cpu can send a Command Completion Signal Disable (CCSD).

- Send CCSD - Module sends CCSD to the CE-ATA device if the send\_ccsd bit is set in the CTRL register; this bit is set only after a response is received for the RW\_BLK.
- Send internal Stop command - Send internally generated STOP (CMD12) command after sending the CCSD pattern. If send\_auto\_stop\_ccsd bit is also set when the controller is programmed to send the CCSD pattern, the Module sends the internally generated STOP command on the CMD line. After sending the STOP command, the Module sets the Auto Command Done bit in the RINTSTS register.

#### 7.3.2.5 Recovery after Command Completion Signal Timeout

If timeout happened while waiting for Command Completion Signal (CCS), the cpu needs to send Command Completion Signal Disable (CCSD) followed by a STOP command to abort the pending ATA command. The cpu can program the Module to send internally generated STOP command after sending the CCSD pattern

- Send CCSD - Set the send\_ccsd bit in the CTRL register.
- Reset bit 13 of the Command register (wait\_prvdata\_complete) to 0 in order to make the Module send the command at once, even though there is a data transfer in progress.
- Send internal STOP command - Set send\_auto\_stop\_ccsd bit in the CTRL register, which programs the cpu controller to send the internally generated STOP command. After sending the STOP command, the Module sets the Auto Command Done bit in the RINTSTS register.

#### 7.3.2.6 Reduced ATA Command Set

It is necessary for the CE-ATA device to support the reduced ATA command subset. The following details discuss this reduced command set.

- IDENTIFY DEVICE - Returns 512-byte data structure to the cpu that describes device-specific information and capabilities. The cpu issues the IDENTIFY DEVICE command only if the MMC block size is set to 512 bytes; any other MMC block size has indeterminate results.

The cpu issues RW\_REG for the ATA command, and the data is retrieved through RW\_BLK.

The cpu controller uses the following settings while sending RW\_REG for the IDENTIFY DEVICE ATA command. The following lists the primary bit

- CMD register setting - data\_expected field set to 0
- CMDARG register settings:
  - Bit [31] set to 0
  - Bits [7:2] set to 128.
- Task file settings:
  - Command field of the ATA task file set to ECh
  - Reserved fields of the task file cleared to 0

- BLKSIZ register bits [15:0] and BYTCNT register - Set to 16

The cpu controller uses the following settings for data retrieval (RW\_BLK):\

- CMD register settings:
  - ccs\_expect set to 1
  - data\_expected set to 1
- CMDARG register settings:
  - Bit [31] set to 0 (Read operation)
  - Data Count set to 1 (16'h0001)
- BLKSIZ register bits [15:0] and BYTCNT register - Set to 512 IDENTIFY DEVICE can be aborted as a result of the CPU issued CMD12.
  - READ DMA EXT - Reads a number of logical blocks of data from the device using the Data-In data transfer protocol. The cpu uses RW\_REG to issue the ATA command and RW\_BLK for the data transfer.
  - WRITE DMA EXT - Writes a number of logical blocks of data to the device using the Data-Out data transfer protocol. The cpu uses RW\_REG to issue the ATA command and RW\_BLK for the data transfer.
  - STANDBY IMMEDIATE - No data transfer (RW\_BLK) is expected for this ATA command, which causes the device to immediately enter the most aggressive power management mode that still retains internal device context.
- CMD Register setting - data\_expected field set to 0
- CMDARG register settings:
  - Bit [31] set to 1
  - Bits [7:2] set to 4
- Task file settings:

- Command field of the ATA task file set to E0h
- Reserved fields of the task file cleared to 0
- BLKSIZ register bits [15:0] and BYTCNT register - Set to 16
  - FLUSH CACHE EXT - No data transfer (RW\_BLK) is expected for this ATA command. For devices that buffer/cache written data, the FLUSH CACHE EXT command ensures that buffered data is written to the device media. For devices that do not buffer written data, FLUSH CACHE EXT returns a success status. The cpu issues RW\_REG for the ATA command, and the status is retrieved through CMD39/RW\_REG; there can be error status for this ATA command, in which case fields other than the status field of the ATA task file are valid.
- The CPU uses the following settings while sending the RW\_REG for STANDBY IMMEDIATE ATA command:
  - CMD register setting - data\_expected field set to 0
  - CMDARG register settings:
    - Bit [31] set to 1
    - Bits [7:2] set to 4
  - Task file settings:
    - Command field of the ATA task file set to EAh
    - Reserved fields of the task file cleared to 0
    - BLKSIZ register bits [15:0] and BYTCNT register - Set to 16

### 7.3.3 Controller/DMA/FIFO Reset Usage

Communication with the card involves the following:

- Controller - Controls all functions of the Module.
- FIFO - Holds data to be sent or received.
- DMA - If DMA transfer mode is enabled, then transfers data between system memory and the FIFO.
- Controller reset - Resets the controller by setting the controller\_reset bit (bit 0) in the CTRL register; this resets the CIU and state machines, and also resets the BIU-to-CIU interface. Since this reset bit is self-clearing, after issuing the reset, wait until this bit is cleared.
- FIFO reset - Resets the FIFO by setting the fifo\_reset bit (bit 1) in the CTRL register; this resets the FIFO pointers and counters of the FIFO. Since this reset bit is self-clearing, after issuing the reset, wait until this bit is cleared.
  - DMA reset - Resets the internal DMA controller logic by setting the dma\_reset bit (bit 2) in the CTRL register, which abruptly terminates any DMA transfer in process. Since this reset bit is self-clearing, after issuing the reset, wait until this bit is cleared.

The following are recommended methods for issuing reset commands:

- Non-DMA transfer mode - Simultaneously sets controller\_reset and fifo\_reset; clears the RAWINTS register @0x44 using another write in order to clear any resultant interrupt.

- Generic DMA mode - Simultaneously sets `controller_reset`, `fifo_reset`, and `dma_reset`; clears the RAWINTS register @0x44 by using another write in order to clear any resultant interrupt. If a "graceful" completion of the DMA is required, then it is recommended to poll the status register to see whether the `dma_request` is 0 before resetting the DMA interface control and issuing an additional FIFO reset.
- In DMA transfer mode, even when the FIFO pointers are reset, if there is a DMA transfer in progress, it could push or pop data to or from the FIFO; the DMA itself completes correctly. In order to clear the FIFO, the software should issue an additional FIFO reset and clear any FIFO underrun or overrun errors in the RAWINTS register caused by the DMA transfers after the FIFO was reset.

### 7.3.4 Error Handling

The Module implements error checking; errors are reflected in the RAWINTS register @0x44 and can be communicated to the software through an interrupt, or the software can poll for these bits. Upon power-on, interrupts are disabled (`int_enable` in the CTRL register is 0), and all the interrupts are masked (bits 0-31 of the INTMASK register; default is 0). Error handling:

- Response and data timeout errors - For response timeout, software can retry the command. For data timeout, the Module has not received the data start bit - either for the first block or the intermediate block - within the timeout period, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the TCBCNT later, the software can decide how many bytes remain to be copied.
- Response errors - Set when an error is received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.
- Data errors - Set when error in data reception are observed; for example, data CRC, start bit not found, end bit not found, and so on. These errors could be set for any block-first block, intermediate block, or last block. On receipt of an error, the software can issue a STOP or ABORT command and retry the command for either whole data or partial data.
- Hardware locked error - Set when the Module cannot load a command issued by software. When software sets the `start_cmd` bit in the CMD register, the Module tries to load the command. If the command buffer is already filled with a command, this error is raised. The software then has to reload the command.
- FIFO underrun/overrun error - If the FIFO is full and software tries to write data in the FIFO, then an overrun error is set. Conversely, if the FIFO is empty and the software tries to read data from the FIFO, an underrun error is set. Before reading or writing data in the FIFO, the software should read
  - the `fifo_empty` or `fifo_full` bits in the Status register.
- Data starvation by cpu timeout - Raised when the Module is waiting for software intervention to transfer the data to or from the FIFO, but the software does not transfer within the stipulated timeout period. Under this condition and when a read transfer is in process, the software
  - Should read data from the FIFO and create space for further data reception. When a transmit operation is in process, the software should fill data in the FIFO in order to start transferring data to the card.

- CRC Error on Command - If a CRC error is detected for a command, the CE-ATA device does not send a response, and a response timeout is expected from the Module. The ATA layer is notified that an MMC transport layer error occurred.
- Write operation - Any MMC Transport layer error known to the device causes an outstanding ATA command to be terminated. The ERR bits are set in the ATA status registers and the appropriate error code is sent to the ATA Error register.
- If  $nIEN=0$ , then the Command Completion Signal (CCS) is sent to the cpu.

If device interrupts are not enabled ( $nIEN=1$ ), then the device completes the entire Data Unit Count if the cpu controller does not abort the ongoing transfer.

During a multiple-block data transfer, if a negative CRC status is received from the device, the data path signals a data CRC error to the BIU by setting the data CRC error bit in the RINTSTS register. It then continues further data transmission until all the bytes are transmitted.

- Read operation - If MMC transport layer errors are detected by the cpu controller, the cpu completes the ATA command with an error status.

The cpu controller can issue a Command Completion Signal Disable (CCSD) followed by a STOP TRANSMISSION (CMD12) to abort the read transfer. The cpu can also transfer the entire Data Unit Count bytes without aborting the data transfer.

## 1. Introduction

---

Many applications need a simple method of communicating data between equipment. The Universal Asynchronous Receiver Transmitter (UART) protocol is standard for such communications. The UART supports the industry standard serial interface and can be used for connecting a modem, Bluetooth IC, or a terminal emulator. The term asynchronous is used because it is not necessary to send clocking information with the data that is sent. The UART interface is fully compliant with industry standard 16C750 from various manufacturers. The UART can also function as an IrDA (Infra-Red Data Exchange) modem by setting a register bit in the UART configuration register bank.

### 1.1 Features

This module has the following features:

- Programmable baud rate with a maximum of 1049 kbaud.
- Programmable data length (5-8 bits).
- Implements only asynchronous UART.
- Transmit break character length indication.
- Programmable one to two stop bits in transmission.
- Odd/Even/Force parity check/generation.
- Frame error, overrun error and break detection.
- Automatic modem flow control.
- Independent control of transmit, receive, line status, data set interrupts and FIFO's.
- SIR-IrDA encoder/decoder (from 2400 to 115 kbaud).
- Supports interrupts.
- Supports DMA transfers.

## 2. General description

---

### 2.1 About UART

UART links are character oriented (the smallest unit of data that can be correctly received or transmitted is a character). Typical applications of asynchronous links are connections between terminals and computer equipment. Two UARTs can communicate using a system like this if parameters, such as the parity scheme and character length, are the same for both transmitter and receiver. The character format of the UART protocol is illustrated in the following figure:

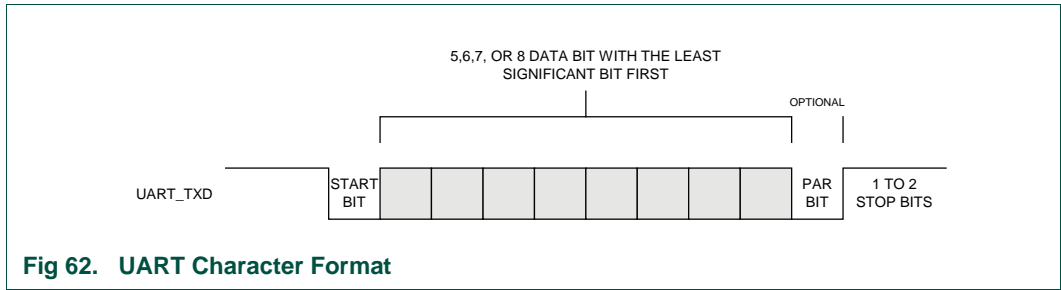

Fig 62. UART Character Format

When data is not transmitted in the UART protocol, a continuous stream of ones is transmitted, called the idle condition. Since the start bit is always a zero, the receiver can detect when real data is once again present on the line. UART also specifies an all-zeros character (start, data, parity, stop), which is used to abort a character transfer sequence.

### 2.2 About IrDA

IrDA stands for infrared (IR) Data Exchange. It's a common name for a suit of protocols for infrared exchange of data between two devices, up to 1 m or 2 m apart (20 to 30 cm for low-power devices). IrDA devices typically have throughput of up to either 115.2 Kbps (Serial IR, SIR). IrDA protocols are implemented in many (smart) mobile phones, PDAs and portable devices, printers and laptop computers. The Infrared Data Association, the industry body that specifies IrDA protocols, was originally founded by Hewlett-Packard and others.

### 2.3 Block diagram

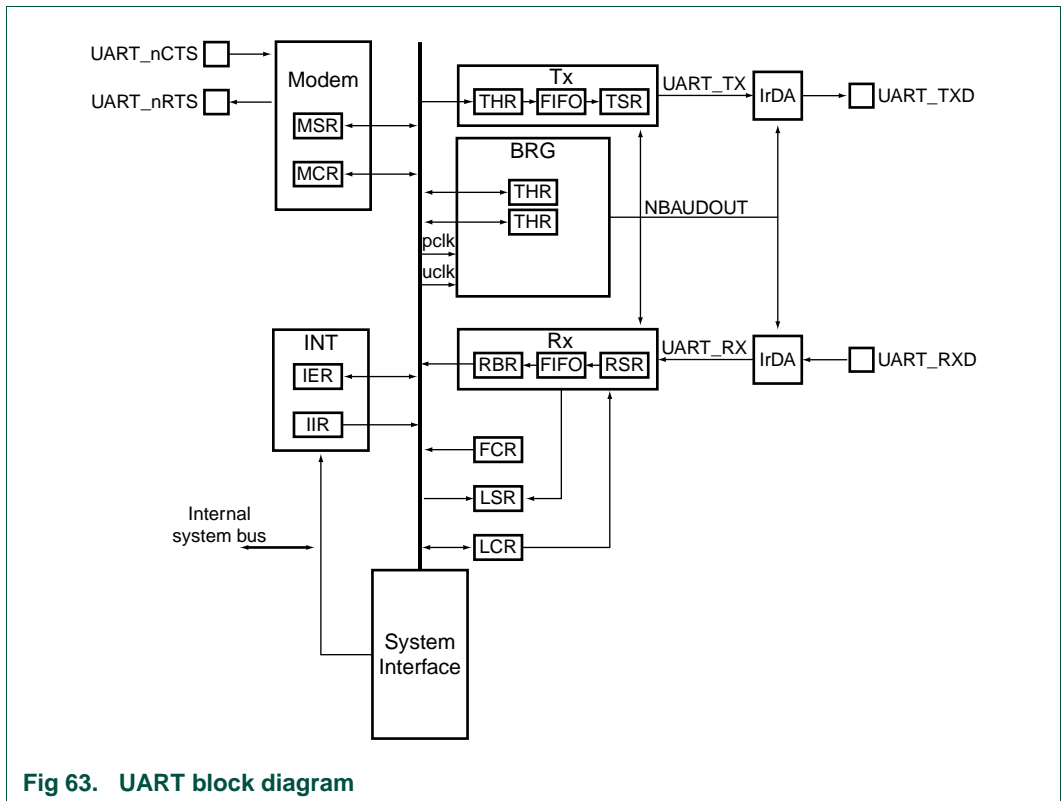

Fig 63. UART block diagram

The UART internal architecture consists of the following modules:

- A APB bus transceiver
- A UART modem block
- A Baud Rate Generator block
- Receive and transmit buffer blocks (respectively Rx, Tx)
- An IrDA block (can be enable/disabled according to the UART register settings).

The UART has two clock domains, an APB clock domain to interface to the rest of the internal system, and a clock domain dedicated to the UART serial interface.

## 2.4 Interface description

### 2.4.1 Clock signals

The UART has two clock inputs:

- The APB\_CLK operates the APB interface and the registers in the software view.
- The U\_CLK is used for UART baud-rate generation and operates most of the UART data-path including the optional IrDA.

The clocks can be asynchronous i.e. need not have a frequency or phase relation. The APB\_CLK frequency can be smaller than, equal to, or higher than the U\_CLK frequency.

**Table 455. Clock Signals of the UART**

Clock Name	Acronym	I/O	Source/ Destination	Description
UART_APB_CLK	APB_CLK	I	CGU	The APB_CLK can be switched off by an external clock gate. In this case the UART registers are not accessible from the APB bus. The UART can still receive and transmit data but will not forward interrupt and DMA status to the CPU and the DMA controller. Frequency should be between 10-50 MHz.
UART_U_CLK	U_CLK	I	CGU	The U_CLK can be switched off by an external clock gate. In this case the UART cannot receive and transmit characters; the APB interface is still operational and can be accessed without deadlocking the APB bus. Frequency should be between 10-50 MHz.

### 2.4.2 Pin connections

**Table 456. UART Signals to pins of the IC for the UART**

Name	Type	Reset	Description
UART_RXD	I	-	Serial Data Receive
UART_TXD	O	-	Serial Data Transmit
mUART_CTS_N	I	-	Modem flow control: Clear to Send
mUART_RTS_N	O	-	Modem flow control: Request to Send

### 2.4.3 Interrupt Request Signals

The UART creates one interrupt signal. The UART has two interrupt modes. If the UART is configured as NHP interrupt mode (see register overview), it will comply to the NHP interrupt standard. If the MODE.NHP bit is cleared, the UART is in standard 750 mode and interrupts should be handled via the IIR/IER registers.

### 2.4.4 Reset Signals

The CGU provides one UART global asynchronous reset signal to the UART block.

### 2.4.5 DMA Transfer Signals

The UART module implements DMA flow control using the following signals:

**Table 457. DMA signals of the UART**

Name	Type	Description
UART_RX_RDY_N	O	UART Rx receive FIFO request information.
UART_TX_RDY_N	O	UART Tx transmit FIFO request information.

## 3. Register overview

**Table 458. Register overview: UART (register base address 0x1500 1000)**

Name	R/W	Address Offset	Description
RBR	R	0x000	Receiver Buffer Register
THR	W	0x000	Transmitter Holding Register
DLL	R/W	0x000	Divisor Latch LSB
DLM	R/W	0x004	Divisor Latch MSB
IER	R/W	0x004	Interrupt Enable Register
IIR	R	0x008	Interrupt Identification Register
FCR	W	0x008	FIFO Control Register
LCR	R/W	0x00C	Line Control Register
MCR	R/W	0x010	Modem Control Register
LSR	R	0x014	Line Status Register
MSR	R	0x018	Modem status Register
SCR	R/W	0x01C	Scratch Register
-	-	0x020	Reserved
ICR	R/W	0x024	IrDA Control Register
FDR	R/W	0x028	Fractional Divider Register
-	-	0x02C	Reserved
POP	W	0x030	NHP Pop Register
MODE	R/W	0x034	NHP Mode Selection Register
-	-	0x038-0xFD4	Reserved
INTCE	W	0xFD8	Interrupt Clear Enable Register
INTSE	W	0xFDC	Interrupt Set Enable Register
INTS	R	0xFE0	Interrupt Status Register
INTE	R	0xFE4	Interrupt Enable Register

**Table 458. Register overview: UART (register base address 0x1500 1000) ...continued**

Name	R/W	Address Offset	Description
INTCS	W	0xFE8	Interrupt Clear Status Register
INTSS	W	0xFEC	Interrupt Set Status Register
-	-	0xFF0-0xFF8	Reserved

## 4. Register description

### 4.1 Receive Buffer Register

**Table 459. Receive Buffer Register (RBR, address 0x1500 1000)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7.0	RBRFirst	R	NA	In FIFO mode (FCR[0] = 1), top of Receiver FIFO. in non-FIFO mode(FCR[0] = 0), value of buffer register.

The Receiver Buffer Register (RBR) can only be accessed if the LCR, DLAB = 0, otherwise the DLL register will be accessed. The RBR register is read-only; writing this address will access the THR register.

In non-FIFO mode (i.e. when FCR[0] is not set), the RBR can store one received character. The value of the RBR can be read via this register. After reading the register the value is undefined until the next character is received.

In FIFO mode i.e. when FCR[0] is set, the value in the register represents the first character in the UART FIFO. In this mode reading a character from the RBR will pop the character from the RBR FIFO. After the read operation the RBR will have the value of the next character in the FIFO. If the FIFO is empty the value of the register will be undefined until the next character is received.

If the UART is configured as Nexperia Home Platform (NHP) compliant by setting the MODE.NHP bit then the RBR register of the UART is protected against speculative read options and reading RBR will not pop the character from the top of the FIFO. Instead the top FIFO character will be popped by writing 0x1 to the POP register.

Bit 0 is the least significant bit and is the first bit serially received. If the UART transmit/receive word length as defined in LCR[1:0] is less than 8 bits per character then the upper bits of the RBR will be 0.

### 4.2 Transmitter Holding Register (THR)

**Table 460. Transmitter Holding Register (THR, address 0x1500 1000)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7.0	THRLast	R	NA	In FIFO mode (FCR[0] = 1), top of Receiver FIFO; in non FIFO mode (FCR[0] = 0), value of buffer register

The Transmitter Holding Register (THR) can only be accessed if LCR, DLAB = 0, otherwise the DLL register will be accessed. The THR register is write-only; reading this address will access the RBR register.

In non FIFO mode (i.e. when FCR[0] is not set), the THR can store one transmit character (In an 'x50 configuration in non FIFO mode the full Tx FIFO depth can still be filled). The value for the THR can be written via this register. After writing the register the value will be transmitted on the UART serial out port (sout). New data can only be written in the register after old data has been transmitted. If new data is written before old data has been transmitted then the new data will be discarded.

In FIFO mode i.e. when FCR[0] is set, the value in the register represents the tail the UART's transmit FIFO/queue. In this mode writing a character to the THR will queue a character for transmission. If the FIFO is full any writes to the THR will be discarded.

Bit 0 is the least significant bit and is the first bit serially transmitted. If the UART transmit/receive word length as defined in LCR[1:0] is less than 8 bits per character then the upper bits of the THR will be ignored.

### 4.3 Divisor Latch register LSB (DLL)

**Table 461. Divisor register Latch LSB (DLL, address 0x1500 1000)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-	-	-	Reserved
7:0		R/W	0x1	Least significant byte of the divisor latch value

The Divisor Latch LSB register (DLL) can only be accessed if LCR.DLAB = 1. If LCR.DLAB = 0 reading from and writing to this address will access RBR and THR. The divisor value is 16 bits of which the most significant bits are stored in the DLM register and the least significant bits are defined in the DLL register.

For an optimal baud-rate the minimum value of the divisor should be set to 3.

The value of the DLL should not be modified while transmitting/receiving data or data may be lost or corrupted.

### 4.4 Divisor latch register MSB

The Divisor Latch MSB register (DLM) can only be accessed if LCR, DLAB = 1. If LCR.DLAB = 0 reading and writing this address will access the IER register.

The value of the DLM should not be modified while transmitting/receiving data or data may be lost or corrupted.

**Table 462. Divisor latch register MSB (DLM, address 0x1500 1004)**

Bit	Symbol	R/W	Reset Value	Description
31:8	reserved	R	0x0	reserved for future use
7:0	DLLVal	R/W	0x1	Most significant byte of the divisor latch value

## 4.5 Interrupt Enable Register (IER)

**Table 463. Interrupt Enable Register (IER, address 0x1500 1004)**

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9	-	-	-	Reserved
8	-	-	-	Reserved
7	CTSIntEn	R/W	0x0	If auto-cts mode is enabled this enables/disables the modem status interrupt generation on a mUART_CTS_N signal transition. If auto-cts mode is disabled a mUART_CTS_N transition will generate an interrupt if MSIntEn is set.
6:4				Reserved
3	MSIntEn	R/W	0x0	Modem Status interrupt enable
2	RLSIntEn	R/W	0x0	Receiver Line Status interrupt enable
1	THREIntEn	R/W	0x0	Transmitter Holding Register Empty interrupt enable
0	RDAIntEn	R/W	0x0	Receive Data Available interrupt enable,

The IER can only be accessed if LCAR, DLAB = 0, otherwise the DLM register will be accessed. The IER register can be read and written.

The IER masks the interrupts from receiver ready, transmitter empty, line status and modem status registers. These interrupts would normally be seen in the IIR register and on the interrupt request output pin (uart\_intreq).

In normal operation a mUART\_CTS\_N signal transition will generate a Modem Status interrupt unless the interrupt has been disabled by clearing the MSIntEn bit in the IER register. In auto-cts mode a transition on mUART\_CTS\_N will trigger an interrupt only if both the MSIntEn and the CTSIntEn bits are set.

In Nexperia Home Platform compliant systems software should use the INTSS and INTSE registers for implementing interrupt service routines.

## 4.6 Interrupt Identification Register (IIR)

**Table 464. Interrupt Identification Register (IIR, address 0x1500 1008)**

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9	-	-	-	Reserved
8	-	-	-	Reserved
7:6	FIFOEn	R	0x0	Copies of FCR[0]
5:4				Reserved
3:1	IntId	R	0x0	Interrupt identification
0	IntStatus	R	0x0	Interrupt status. If 0 then interrupt is pending; if 1 no interrupt is pending

Bits [7:6] of this register are copies of the FCR.FIFOEn bit.

If the `IntStatus` bit is 0, the `IntId` bits identify the type of interrupt according to [Table 22–465](#). If the `IntStatus` bit is 1 no interrupt is pending and the `IntId` bits will be zero.

**Table 465. Interrupt Identification and Priorities**

INTD	Priority	Type	SET	CLEAR
0x3	1 (highest)	Receiver Line Status	Set on an overrun error, parity error, framing error or break indication	Reading the LSR
0x2	2	Received Data Available	Receiver data available (FIFO disabled) or trigger level reached in FIFO mode (FIFO enabled)	Reading the RBR (FIFO disabled) or the FIFO level drops below the trigger level (FIFO enabled).
0x6	2	Character time-out; only generated if the FIFO is enabled	Set on an overrun error, parity error, framing error or break indication	Reading the RBR
0x1	3	Transmitter Holding Register empty	Transmitter Holding Register empty (THRE)	Reading the IIR if IIR value is 0x1, or writing to THR
0x0	4 (lowest)	Modem status	Set on transition of <code>cts_an</code>	Reading the MSR

The IIR only indicates an interrupt if the corresponding bit in the IER register is set.

If multiple interrupts are pending only the highest priority interrupt will be indicated in the `IntId` bits of the IIR. Only after clearing a higher priority interrupt a low priority interrupt will be indicated. The UART provides four prioritized levels of interrupts:

Priority 1 - Receiver line status (highest priority)

Priority 2 - Receiver data available or receiver character time-out

Priority 3 - Transmitter holding register empty

Priority 4 - Modem status (lowest priority)

Interrupts can be cleared by reading the register causing the interrupt. The LSR, THRE can be cleared either by reading the IIR or writing to the THR register. The LSR, THRE interrupt will only be cleared by an IIR read if the LSR, THRE interrupt is the highest pending interrupt.

This interrupt is activated when THR FIFO is empty provided certain initialization conditions have been met. These initialization conditions are intended to give the THR FIFO a chance to fill up with data to eliminate many LSR, THRE interrupts from occurring at system start-up. The initialization conditions implement a one character delay minus the stop bit whenever `THRE=1` and there have not been at least two characters in the LSR, THR at one time since the last LSR, `THRE=1` event.

This delay is provided to give CPU time to write data to THR without a THRE interrupt to decode and service. A LSR, THRE interrupt is set immediately if the THR FIFO has held two or more characters at one time and currently, the THR is empty.

Note: the interrupt register can indicate multiple interrupts concurrently.

In Nexperia Home Platform compliant systems software should use the INTSS and INTSE register for implementing interrupt service routines since the LSR, THRE bit is not protected for speculative read operations

## 4.7 FIFO Control Register (FCR)

**Table 466. FIFO Control Register (FCR, address 0x1500 1008)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7:6	RxTrigLevel	W	0x0	Receiver trigger level selection; The Rx FIFO can store 64 characters in total. RxTrigLevel = 0x0: trigger point at character 1 RxTrigLevel = 0x1: trigger point at character 16 RxTrigLevel = 0x2: trigger point at character 32 Rx TrigLevel = 0x3: trigger point at character 56
5:4				Reserved
3	DMAMode	W	0x0	DMA mode select. When IIR, FIFOEn is set, setting DMAMode causes the rx_rdy_n, and tx_rdy_n to change from mode 0 to mode 1.
2	TxFIFORst	W	0x0	Transmitter FIFO reset. When set clears all bytes in the transmit FIFO and resets its counter to 0. The TSR is not cleared. The logic 1 that is written to this bit position is self-clearing.
1	RxFIFORst	W	0x0	Receiver FIFO reset. When set clears all bytes in the receiver FIFO and resets its counter. The RSR is not cleared. The logic 1 that is written to this bit position is self-clearing.
0	FIFOEnable	W	0x0	Transmit and receive FIFO enable. 0: UART Rx and Tx FIFOs disabled. 1: UART Rx and Tx FIFOs enabled and other FCR bits activated.

The FIFO Control Register (FCR) is write-only; reading this address will access the IIR register. The value of the FCR should not be modified while receiving/transmitting data or data might get lost or corrupted.

## 4.8 Line Control Register (LCR)

**Table 467. Line Control Register (LCR, address 0x1500 100C)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7	DLAB	R/W	0x0	Divisor Latch Access bit. If set enables access to the divisor latch registers, if cleared enables access to the RBR, THR, IER registers.
6	BrkCtrl	R/W	0x0	Break control bit. BrkCtrl is set to force a break condition; i.e., a condition where sout is forced to the spacing (low) state. When BrkCtrl is cleared, the break condition is disabled and has no effect on the transmitter logic; it only affects the serial output.

**Table 467. Line Control Register (LCR, address 0x1500 100C)**

Bit	Symbol	R/W	Reset Value	Description
5	ParStick	R/W	0x0	If parity is enabled by setting the ParEn bit the ParStick bit enables the stick parity mode.
4	ParEven	R/W	0x0	If parity is enabled by setting the ParEn bit the ParEvenSel bit selects between even, odd, stick 0 and stick 1 parity.
3	ParEn	R/W	0x0	Parity enable. Setting this bit appends a parity bit to each transmission and the receiver checks each word for parity errors. Clearing this bit disables parity transmission and receiver parity checking.
2	StopBitNum	R/W	0x0	Number of stop bits selector. The number of stop bits depends on the value of WdLenSel and StopBitNum.
1:0	WdLenSel	R/W	0x0	Word length selector

**Table 468. UART Parity Generation Options**

LCR.PAREN	LCR.PAREVEN	LCR.PARSTICK	DESCRIPTION
0	x	x	Parity is disabled. No parity bit will be transmitted and no parity will be checked during receive.
1	0	0	Odd parity mode. Data+parity bit will have an odd number of 1s
1	1	0	Even parity mode. Data+parity bit will have an even number of 1s
1	0	1	Stick 1 mode: parity is always 1
1	1	1	Stick 0 mode: parity is always 0

The next table lists the word length and stop bit options available in the UART. Apart from the BrkCtrl bit the value of the LCR should not be modified while transmitting/receiving data or data might get lost or corrupted.

**Table 469. UART Character Length and Stop Bits Generation Options**

LCR.WDLENS EL	LCR.STOPBIT	CHARACTER LENGTH	NUMBER OF STOP BITS
0x0	0	5	1
0x1	0	6	1
0x2	0	7	1
0x3	0	8	1
0x0	1	5	1.5
0x1	1	6	2
0x2	1	7	2
0x3	1	8	2

## 4.9 MCR (Modem Control Register)

**Table 470. Modem Control Register (MCR, address 0x1500 1010)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7	AutoCTSEn	R/W	0x0	Auto-cts flow control enable
6	AutoRTSEn	R/W	0x0	Auto-rts flow control enable
5				Reserved
4	LoopEn	R/W	0x0	Loop-back mode enable. When LoopEn is set, registers MCR[3:0] are forced to "0000"
3	-	R/W	0x0	Reserved
2	-	R/W	0x0	Reserved
1	RTS	R/W	0x0	Request To Send. If the AutoRTSEn bit is set the RTS bit is read-only and will reflect the current state of the mUART_RTS_N output. If the AutoRTSEn is cleared then the RTS bit is the inverse control for the mUART_RTS_N output.
0	-	R/W	0x0	Reserved

## 4.10 LSR (Line Status Register)

**Table 471. Line Status Register (LSR, address 0x1500 1014)**

Bit	Symbol	R/W	Reset Value	Description
31:4	-			Reserved
7	RxEr	R	0x0	Error in receiver FIFO. 0 = No error (normal default condition). 1 = At least one parity error, framing error or break indication is in the current FIFO data. This bit is cleared when LSR register is read.
6	TEMT	R	0x1	Transmitter empty: TSR and THR are empty. This bit is set to a logic 1 whenever the transmit holding register and the transmit shift register are both empty. It is reset to logic 0 whenever either the THR or TSR contains a data character. In the FIFO mode, this bit is set to '1' whenever the transmit FIFO and transmit shift register are both empty.
5	THRE	R	Undefined	Transmitter Holding Register empty. This bit indicates that the UART is ready to accept a new character for transmission. In addition, this bit causes the UART to issue an interrupt to CPU when the THR interrupt enable is set. The THRE bit is set to a logic 1 when a character is transferred from the transmit holding register into the transmitter shift register. The bit is reset to a logic 0 concurrently with the loading of the transmitter holding register by the CPU. In the FIFO mode, this bit is set when the transmit FIFO is empty; it is cleared when at least 1 byte is written to the transmit FIFO.

Table 471. Line Status Register (LSR, address 0x1500 1014) ...continued

Bit	Symbol	R/W	Reset Value	Description
4	BI	R <sup>[1]</sup>	Undefined	Break indication. 0 = No break condition (normal default condition). 1 = The receiver received a break signal (RX was a logic 0 for one character frame time). In the FIFO mode, only one break character is loaded into the FIFO. This bit is cleared when the LSR register is read.
3	FE	R <sup>[1]</sup>	Undefined	Framing error. 0 = No framing error (normal default condition). 1 = Framing error. The receive character didn't have a valid stop bit(s). In the FIFO mode, this error is associated with the character at the top of the FIFO.
2	PE	R <sup>[1]</sup>	Undefined	Parity error. 0 = No parity error (normal default condition). 1 = Parity error. The receive character does not have correct parity information and is suspect. In the FIFO mode, this error is associated with the character at the top of the FIFO. This bit is cleared when the LSR register is read.
1	OE	R <sup>[1]</sup>	Undefined	Overrun error. 0 = No overrun error (normal default condition). 1 = Overrun error. A data overrun error occurred in the receive shift register. This happens when additional data arrives while the FIFO is full. In this case, the previous data in the shift register is overwritten. Note that under this condition, the data byte in the receive shift register is not transferred into the FIFO; therefore the data in the FIFO is not corrupted by the error. This bit is cleared when the LSR register is read.
0	DR	R	0x0	Data ready 0 = No data in receive holding register or FIFO (normal default condition). 1 = Data has been received and is saved in the receive holding register or FIFO.

[1] In Nexperia Home Platform compliant systems SW should not use the BI/FE/PE/OE bits in the LSR since these are sensitive to speculative read operations. The corresponding INTSS bits should be used instead. Reading LSR, IIR or INTSS will not have side effects on the value of the bits in INTSS.

Bytes are transferred from THR to TSR as soon as 50% of the start bit has been transmitted by the TSR. The LSR.THRE bit is updated as soon as a byte has been transferred from THR to TSR or if a byte is written into the THR. The LSR.TEMT bit is updated as soon as 50% of the first stop bit has been transmitted or if a byte is written into the THR.

## 4.11 MSR (Modem Status Register)

**Table 472. Modem Status Register (MSR, address 0x1500 1018)**

Bit	Symbol	R/W	Reset Value	Description
31:5	-			Reserved
4	CTS	R <sup>[1]</sup>	0x0	Clear To Send. CTS functions as a modem flow control signal input if it is enabled. Flow control (when enabled) allows starting and stopping the transmissions based on the external modem CTS signal. A logic 1 at the CTS pin will stop the UART transmissions as soon as current character has finished transmission. Normally CTS is the complement of the mUART_CTS_N input. However, in the loop-back mode, this bit is equivalent to the RTS bit in the MCR register.
3:1	-			Reserved
0	DCTS	R <sup>[1]</sup>	0x0	Delta Clear To Send. This bit is set as soon as CTS changes its value. The bit is cleared by a MSR read.

[1] In Nexperia Home Platform compliant systems SW should not use the BI/FE/PE/OE bits in the LSR since these are sensitive to speculative read operations. The corresponding INTSS bits should be used instead. Reading LSR, IIR or INTSS will not have side effects on the value of the bits in INTSS.

## 4.12 SCR (Scratch Register)

**Table 473. Scratch Register (SCR, address 0x1500 101C)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7:0	SCRVal	R/W	0x0	Scratch Value

The scratch register is not used by the UART. It can be used by software as a temporary storage.

## 4.13 ICR (IrDA Control Register)

**Table 474. IrDA Control Register (ICR, address 0x1500 1024)**

Bit	Symbol	R/W	Reset Value	Description
31:6	-			Reserved
5:3	PulseDiv	R/W	0x0	Configures of pulse in fixed pulse width mode. Only relevant if FixPulseEn is set.
2	FixPulseEn	R/W	0x0	Enables IrDA fixed pulse width mode
1	IrDAInv	R/W	0x0	If true the serial input is inverted; if false the input is not inverted. The serial output is not affected by the value of this bit.
0	IrDAEn	R/W	0x0	If true, enable IrDA; if false disable IrDA and pass UART sin/sout transparently.

The value of the ICR should not be modified while transmitting/receiving data or data may be lost or corrupted.

The IrDA.PulseDiv bits are used for configuring the pulse width of the fixed pulse width mode of the UART. The value of these bits should be configured such that the resulting pulse width is at least  $1.63 \mu\text{s}$   $T_{U\_CLK}$  is the period time of clock U\_CLK.

**Table 475. IrDA Pulse Width**

IRDA.FIXPULSEEN	IRDA.PULSEDIV	IRDA TRANSMITTERPULSE WIDTH [US]
0	x	3 / (16 x baud-rate)
1	0	2 x $T_{u\_clk}$
1	1	4 x $T_{u\_clk}$
1	2	8 x $T_{u\_clk}$
1	3	16 x $T_{u\_clk}$
1	4	32 x $T_{u\_clk}$
1	5	64 x $T_{u\_clk}$
1	6	128 x $T_{u\_clk}$
1	7	256 x $T_{u\_clk}$

#### 4.14 FDR (Fractional Divider Register)

**Table 476. Fractional Divider Register (FDR, address 0x1500 1028)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-			Reserved
7:4	MulVal	R/W	0x1	Baud-rate pre-scaler multiplier value
3:0	DivAddVal	R/W	0x0	Baud-rate generation pre-scaler divisor value

The FDR register controls the clock pre-scaler for the baud rate generation. The clock can be pre-scaled by a value of  $MulVal / (MulVal + DivAddVal)$ . For details see [Section 22–5.5](#).

The value of MulVal and DivAddVal should comply to the following expressions:

- $1 \leq MulVal \leq 15$
- $0 \leq DivAddVal \leq 14$
- $DivAddVal < MulVal$

If the register value does not comply to the above expression, then the fractional divider output is undefined.

If DivAddVal is zero then the fractional divider is disabled and the clock will not be divided.

The value of the FDR should not be modified while transmitting/receiving data or data may be lost or corrupted.

## 4.15 NHP POP Register

Table 477. NHP POP Register (POP, address 0x1500 1030)

Bit	Symbol	R/W	Reset Value	Description
31:1	-			Reserved
0	PopRBR	W	0x0	Setting this bit will pop the first item from the Receiver Buffer Register's FIFO as if RBR were read in non NHP mode. The bit will clear automatically.

The POP register is a write-only register. Reading the register will return 0x0.

In 'NHP mode' which protects the UART from speculative reads the PopRBR bit in the POP register can be used to pop the first data element from the RBR FIFO as if the RBR register were read in non 'NHP mode'.

Typically in a NHP mode application each RBR read operation is followed by writing the PopRBR bit to remove the top read data from the FIFO.

## 4.16 Mode Selection Register

Table 478. Mode Selection Register (Mode, 0x1500 1034)

Bit	Symbol	R/W	Reset Value	Description
31:1	-			Reserved
0	NHP	R/W	0x0	Setting this bit will switch the UART in 'NHP mode' and protect the UART RBR from speculative reads; RBR needs to be popped explicitly via the POP register. Intreq is derived from INTS instead of IIR. Clearing the bit will switch the UART in 'x50 mode'.

After reset the UART will be in non NHP compliant, normal 750-compliant mode in which read operations will have side effects. After setting the NHP bit the UART will be in NHP compliant mode which will have two implications:

- RBR read operations will have no side effects. LSR, IIR and MSR reads will still have side effects, in NHP mode the speculative read sensitive bits in the LSR/IIR/MSR registers should not be used by SW. Instead SW should use the INTS register for determining the state of modem, line and interrupt.
- In NHP mode the uart\_intreq output will be derived from the INTS register instead of the IIR register.

## 4.17 INTCE (Interrupt Clear Enable Register)

Table 479. Interrupt Clear Enable Register (INTCE, address 0x1500 1FD8)

Bit	Symbol	R/W	Reset Value	Description
31:16	-	-	-	Reserved
15	OEIntEnClr	W	0x0	Overrun Error Interrupt Enable Clear
14	PEIntEnClr	W	0x0	Parity Error Interrupt Enable Clear

**Table 479. Interrupt Clear Enable Register (INTCE, address 0x1500 1FD8)**

Bit	Symbol	R/W	Reset Value	Description
13	FEIntEnClr	W	0x0	Frame Error Interrupt Enable Clear
12	BIIntEnClr	W	0x0	Break Indication Interrupt Enable Clear
11:10	-	W	0x0	Reserved
9	ABTOIntEnClr	W	0x0	Auto-Baud Time-Out Interrupt Enable Clear
8	ABEOIntEnClr	W	0x0	End of Auto-Baud Interrupt Enable Clear
7	-			Reserved
6	RxDAIntEnClr	W	0x0	Receiver Data Available Interrupt. Enable Clear
4	THREIntEnClr	W	0x0	Transmitter Holding Register Empty Interrupt Enable Clear
3:1	-	-	-	Reserved
0	DCTSIntEnClr	W	0x0	Delta Clear To Send Interrupt Enable Clear

The register bits are one-shot registers and automatically cleared.

#### 4.18 INTSE (Interrupt Set Enable Register)

**Table 480. Interrupt Set Enable Register (INTSE, address 0x1500 1FDC)**

Bit	Symbol	R/W	Reset Value	Description
31:16	-			Reserved
15	OEIntEnSet	W	0x0	Overrun Error Interrupt Enable Set
14	PEIntEnSet	W	0x0	Parity Error Interrupt Enable Set
13	FEIntEnSet	W	0x0	Frame Error Interrupt Enable Set
12	BIIntEnSet	W	0x0	Break Indication Interrupt Enable Set
11:10	-			Reserved
9	ABTOIntEnSet	W	0x0	Auto-Baud Time-Out Interrupt Enable Set
8	ABEOIntEnSet	W	0x0	End of Auto-Baud Interrupt Enable Set
7	-			Reserved
6	RxDAIntEnSet	W	0x0	Receiver Data Available Interrupt. Enable Set
5	RxTOIntEnSet	W	0x0	Receiver Time-Out Interrupt Enable Set
4	THREIntEnSet	W	0x0	Transmitter Holding Register Empty Interrupt Enable Set
3:1	-	-	-	Reserved
0	DCTSIntEnSet	W	0x0	Delta Clear To Send Interrupt Enable Set

The register bits are one-shot registers and automatically cleared.

## 4.19 INTS (Interrupt Status Register)

**Table 481. Interrupt Status Register (INTS, address 0x1500 1FE0)**

Bit	Symbol	R/W	Reset Value	Description
31:16	-			Reserved
15	OEInt	R	0x0	Overrun Error Interrupt. Set if RBR overrun. Cleared by setting INTCS.OEIntClr
14	PEInt	R	0x0	Parity Error Interrupt. Set if top of RBR has parity error. Cleared by popping RBR.
13	FEInt	R	0x0	Frame Error Interrupt. Set if top of RBR has framing error. Cleared by popping RBR.
12	BIInt	R	0x0	Break Indication Interrupt. Set if top of RBR has break indication. Cleared by popping RBR.
11:10	-			Reserved
9	ABTOInt	R	0x0	Auto-Baud Time-Out Interrupt. Set on auto-baud time-out. Cleared by setting INTCS.ABTOIntClr
8	ABEOInt	R	0x0	End of Auto-Baud Interrupt. Set at end of auto-baud. Cleared by setting INTCS.ABEOIntClr.
7	-			Reserved
6	RxDAInt	R	0x0	Receiver Data Available Interrupt. Cleared by popping RBR below FIFO level.
5	RxTOInt	R	0x0	Receiver Time-Out Interrupt. Cleared by popping RBR, receiving new character or setting the INTCS.RxTOIntClr bit.
4	THREInt	R	0x0	Transmitter Holding Register Empty Interrupt. Set if THR is empty. Cleared by writing THR or setting INTCS.THREIntClr
3:1	-	-	-	Reserved
0	DCTSInt	R	0x0	Delta Clear To Send Interrupt. Set on change of CTS. Cleared by setting INTCS.DCTSIntClr.

Only a limited number of bits from the NHP Interrupt Status Register can be set and cleared by software. The INTS.RxDAInt/PEInt/FEInt/BIInt bits cannot be set/cleared from SW. These bits are controlled by HW.

## 4.20 INTE (Interrupt Enable Register)

**Table 482. Interrupt Enable Register (INTE, address 0x1500 1FE4)**

Bit	Symbol	R/W	Reset Value	Description
31:16	-			Reserved
15	OEIntEn	R	0x0	Overrun Error Interrupt Enable
14	PEIntEn	R	0x0	Parity Error Interrupt Enable
13	FEIntEn	R	0x0	Frame Error Interrupt Enable
12	BIIntEn	R	0x0	Break Indication Interrupt Enable
11:10	-			Reserved
9	ABTOIntEn	R	0x0	Auto-Baud Time-Out Interrupt Enable
8	ABEOIntEn	R	0x0	End of Auto-Baud Interrupt Enable
7	-			Reserved

**Table 482. Interrupt Enable Register (INTE, address 0x1500 1FE4) ...continued**

Bit	Symbol	R/W	Reset Value	Description
6	RxDAIntEn	R	0x0	Receiver Data Available Interrupt. Enable
5	RxTOIntEn	R	0x0	Receiver Time-Out Interrupt Enable
4	THREIntEn	R	0x0	Transmitter Holding Register Empty Interrupt Enable
3:1	-	-	-	Reserved
0	DCTSIntEn	R	0x0	Delta Clear To Send Interrupt Enable

## 4.21 INTCS (Interrupt Clear Status Register)

**Table 483. Interrupt Clear Status Register (INTCS, address 0x1500 1FE8)**

Bit	Symbol	R/W	Reset Value	Description
31:16	-			Reserved
15	OElntClr	W	0x0	Overrun Error Interrupt Clear
14:10	-			Reserved
9	ABTOIntClr	W	0x0	Auto-Baud Time-Out Interrupt Clear. Alias of the ACR.ABTOIntClr bit
8	ABEOIntClr	W	0x0	End of Auto-Baud Interrupt Clear. Alias of the ACR.ABEOIntClr bit
7:6	-			Reserved
5	RxTOIntClr	W	0x0	Receiver Time-Out Interrupt Clear
4	THREIntClr	W	0x0	Transmitter Holding Register Empty Interrupt Clear
3:1	-	-	-	Reserved
0	DCTSIntClr	W	0x0	Delta Clear To Send Interrupt Clear

The register bits are one-shot registers and automatically cleared.

## 4.22 INTSS (Interrupt Set Status Register)

**Table 484. Interrupt Set Status Register (INTSS, address 0x1500 FEC)**

Bit	Symbol	R/W	Reset Value	Description
31:16	-			Reserved
15	OElntSet	W	0x0	Overrun Error Interrupt Set
14:10	reserved	W	0x0	reserved for future use
9	ABTOIntSet	W	0x0	Auto-Baud Time-Out Interrupt Set
8	ABEOIntSet	W	0x1	End of Auto-Baud Interrupt Set
7:6	-			Reserved
5	RxTOIntSet	W	0x0	Receiver Time-Out Interrupt Set
4	THREIntSet	W	0x0	Transmitter Holding Register Empty Interrupt Set
3:1	-	-	-	Reserved
0	DCTSIntSet	W	0x0	Delta Clear To Send Interrupt Set

The register bits are one-shot registers and automatically cleared.

## 5. Functional Description

### 5.1 Serial Interface

[Figure 22–64](#) shows the protocol on the serial interfaces (sin\_a, sout) of the UART.

**Fig 64. UART Serial Interface Protocol**

The UART line control register configures the following:

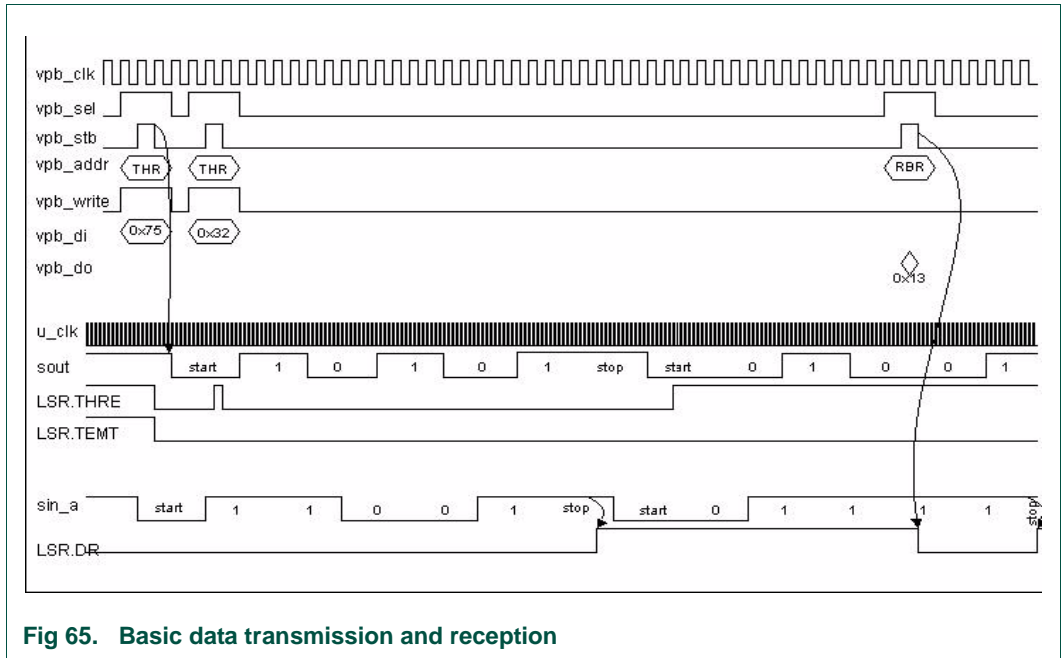

- The number of bits in a receive and transmit character  
The parity type: no/even/odd/stick-high/stick-low parity  
The number of stop bits: 1, 1.5 or 2.

The length of each bit on the serial interface corresponds to  $16 \times \text{baudout\_n}$  pulses for transmit and  $16 \times \text{baudin\_an}$  pulses for receive

The character time of a UART is defined as the time it takes to transmit or receive a single character including start bit, optional parity bit, and all stop bits.

### 5.2 Basic receive and transmit

[Figure 22–65](#) illustrates a basic UART transmission and reception.

**Fig 65. Basic data transmission and reception**

In this example two characters are written via the APB interface in the THR FIFO. After some clock domain synchronization delays the TSR will read the character from the FIFO and start transmission.

After writing the THR the THRE (Transmitter Holding Register Empty) bit in the Line status Register will be de-asserted together with the TEMT (Transmitter Empty) bit in the same register. The THRE bit will get asserted as soon as the character is transferred from the THR to the TSR i.e. as soon as THR is empty again. The TEMT bit will remain de-asserted as long as there is a character in the THR or TSR.

In this example only the five least significant bits in the byte get transmitted i.e. the LCR.WdLenSel bits are set to 0x0.

While transmitting data the UART receives data on its sin\_a input. After receiving the stop bit the data is written in the RBR and the Data Ready bit in the Line Status Register is set (LSR.DR = 1). The CPU reads the character from the RBR which clears the LSR.DR bit.

### 5.3 Loop-back mode

The UART's loop-back mode is activated by setting the MCR.LoopEn bit. In loop-back mode the UART's serial output is looped back to the serial input. Activating the modem loop-back will also loop-back the modem output signals to the modem inputs signals. These loop-backs are realized internally in the UART. In loop-back mode the UART's output pins will be inactive (high). In loop-back mode the UART's input will be disconnected.

Note that loop-back can be used in IrDA mode on the IrDA signals.

## 5.4 Break mode

Transmission of a break condition is controlled by the LCR.BrkCtrl bit. When enabled (setting the bit), the Break control bit causes a break condition to be transmitted. While break control is enabled the UART's output is forced to a low (logic 0) state. This condition exists until disabled by setting LCR.BrkCtrl to a logic 0. On the receiver side break conditions are detected in the LSR.BI bit. In the FIFO mode, only one break character is loaded into the FIFO. Receiving a break condition will trigger a Receiver Line Status interrupt if the interrupt is enabled.

## 5.5 Baud-rate generation

The UART baud-rate generator generates the UART baud-rate for transmission. A single character bit is transmitted in  $N \times \text{baudout}_n$  clock cycles, where  $N = 16$ . The UART receiver uses  $16 \times \text{baudin}_n$  to capture a single character bit. When the transmitter and receiver use the same baud-rate, an external loop-back can connect the  $\text{baudout}_n$  output to the  $\text{baudin}_n$  input. [Figure 22-66](#) illustrates the UART baud-rate generator architecture.

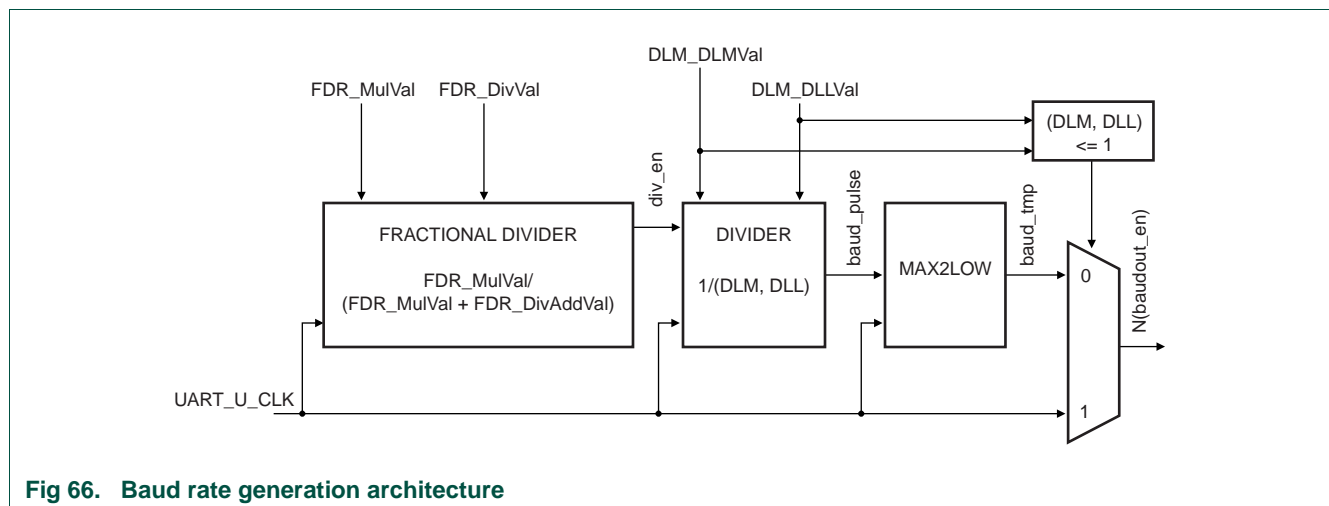

Fig 66. Baud rate generation architecture

The baud-rate generator consists of the following:

- A  $\text{MulVal}/(\text{MulVal}+\text{DivAddVal})$  fraction divider. The fractional divider can multiply the  $u\_clk$  frequency by an  $\text{MulVal}/(\text{MulVal}+\text{DivAddVal})$  ratio, where  $\text{MulVal}$  and  $\text{DivAddVal}$  both are 4 bits values. The  $\text{MulVal}/(\text{MulVal}+\text{DivAddVal})$  ratio can be programmed through the Fractional Divider Register (FDR). The fractional divider can be bypassed by defining  $\text{DivAddVal}$  to zero.
- A  $1/X$  divider. The  $1/X$  can divide the clock generated by the fractional divider by another 16-bit value  $X$ . The 16-bit  $X$  divisor value consists of two parts: a most significant part (Divisor Latch MSB) and a least significant part (Divisor Latch LSB). DLL and DLM can be programmed via the corresponding registers
- A max2low circuit which limits the low time of the  $\text{baudout}_n$  to a maximum of two  $u\_clk$  cycles.
- A multiplexer and control logic passes the  $u\_clk$  to the  $\text{baudout}_n$  output if the divisor value is smaller than or equal to one, otherwise the  $\text{baudout}_n$  will be generated by the dividers.

Figure 22–67 illustrates three examples of the baud-rate generator.

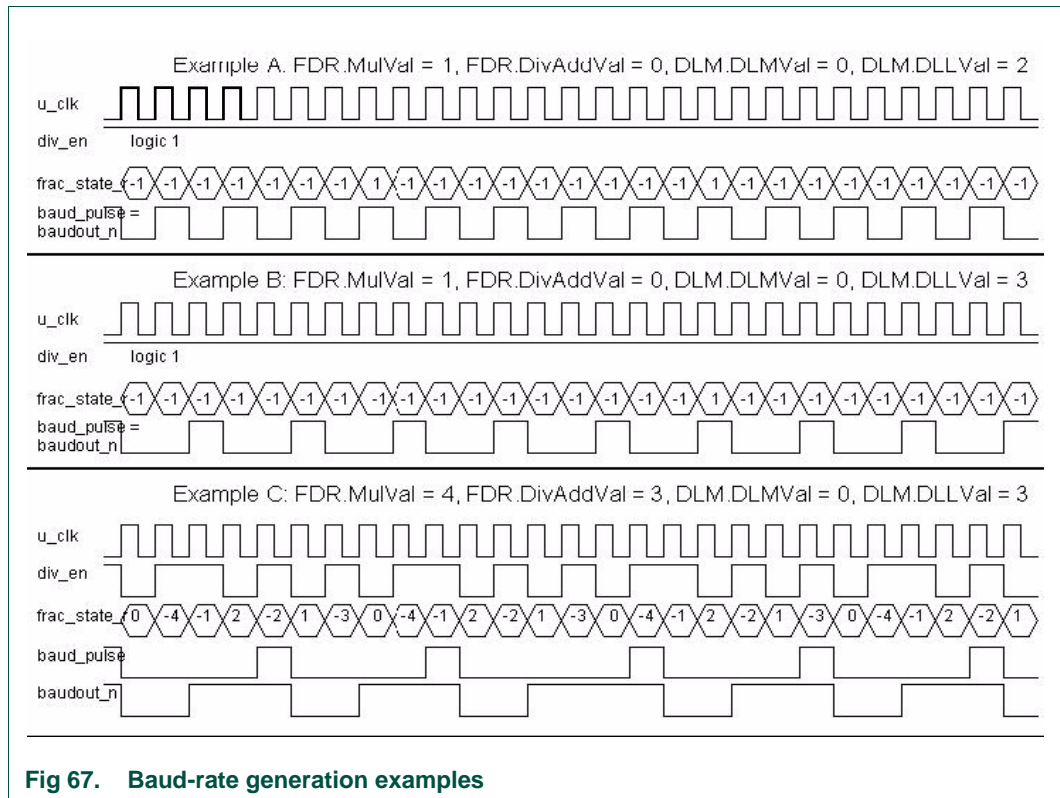

Fig 67. Baud-rate generation examples

In example A the fractional divider is bypassed while the second divider is dividing by 2. In example B the fractional divider is bypassed while the second divider is dividing by 3. In example C the fractional divider is multiplying the clock by  $4/(3+4)=4/7$  while the second divider divides by 3.

Table 22–485 lists the baud-rates for UART\_U\_CLK = 12 MHz. All baud rates were calculated with and without the fractional divider. Note that the error between actual baud rate and desired baud rate is always smaller when using the fractional divider clock pre-scaling.

Table 485. Baud rates for UART\_U\_CLK = 12 MHz

desired UART baudrate [Hz]	Fractional divider off (DivAddVal = 0)			Fractional divider on (DivAddVal > 0)				
	actual UART baudrate [Hz]	{DLM, DLL} divisor used to generate 16X Baud-rate	Relative error %	actual UART baudrate	Relative error %	{DLM, DLL} divisor used to generate 16X Baud-rate	DivAddVal [dec]	MulVal [dec]
50	50	15000	0.000	50	0.0000	15000	0	2

750000	750000	1	0.000	750000	0.0000	1	0	1

### 5.5.1 Algorithm to determine fractional divider settings

The FDR register ([Table 22–476](#)) controls the clock pre-scaler for the baud rate generation. The reset value of the register keeps the fractional capabilities of UART disabled making sure that UART is fully software and hardware compatible with UARTs not equipped with this feature.

The UART baud rate can be calculated as:

(3)

$$UART_{baudrate} = \frac{UCLK}{16 \times (256 \times DLM + DLL) \times \left(1 + \frac{DivAddVal}{MulVal}\right)}$$

Where U\_CLK is the peripheral clock, DLM and DLL are the standard UART baud rate divider registers, and DIVADDVAL and MULVAL are UART fractional baud rate generator specific parameters.

The value of MULVAL and DIVADDVAL should comply to the following conditions:

1.  $1 \leq MulVal \leq 15$
2.  $0 \leq DivAddVal \leq 14$
3.  $DivAddVal < MulVal$

The value of the FDR should not be modified while transmitting/receiving data or data may be lost or corrupted.

If the FDR register value does not comply to these requests, the fractional divider output is undefined. If DivAddVal is zero, the fractional divider is disabled, and the clock will not be divided.

#### 5.5.1.1 Baud rate calculation

UART can operate with or without using the Fractional Divider. In real-life applications it is likely that the desired baud rate can be achieved using several different Fractional Divider settings. The following algorithm illustrates one way of finding a set of DLM, DLL, MulVal, and DivAddVal values. Such set of parameters yields a baud rate with a relative error of less than 1.1% from the desired one.

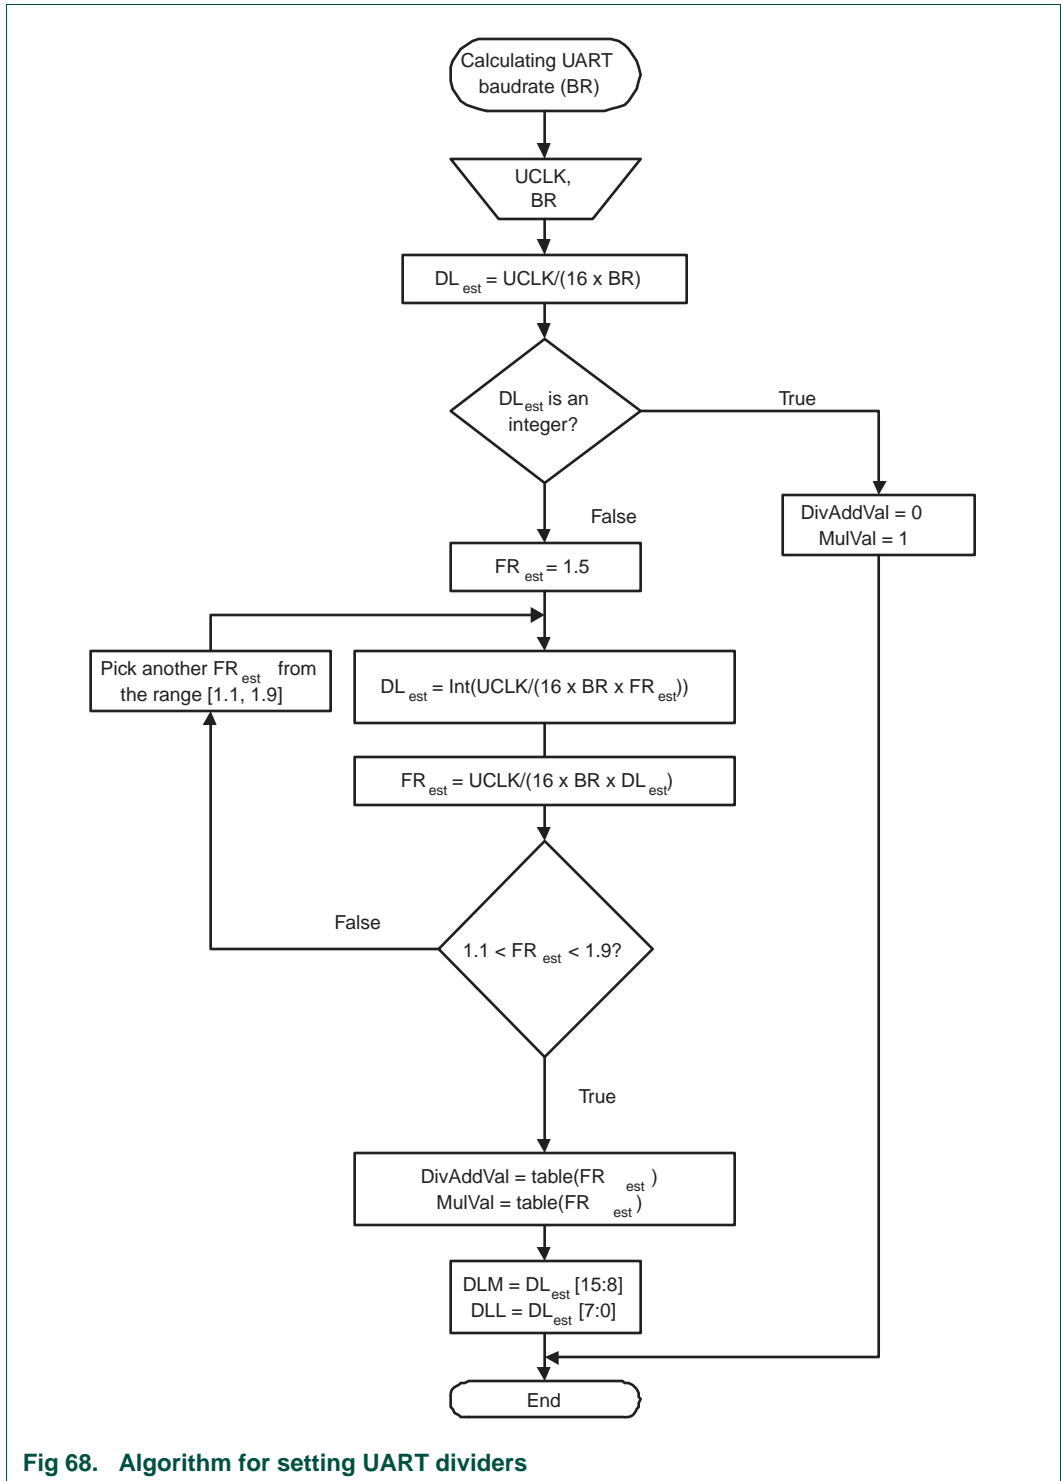

Fig 68. Algorithm for setting UART dividers

Table 486. Fractional Divider setting look-up table

FR	DivAddVal/ MulVal	FR	DivAddVal/ MulVal	FR	DivAddVal/ MulVal	FR	DivAddVal/ MulVal
1.000	0/1	1.250	1/4	1.500	1/2	1.750	3/4
1.067	1/15	1.267	4/15	1.533	8/15	1.769	10/13
1.071	1/14	1.273	3/11	1.538	7/13	1.778	7/9

1.100	1/10	1.333	1/3	1.583	7/12	1.833	5/6
1.111	1/9	1.357	5/14	1.600	3/5	1.846	11/13
1.125	1/8	1.364	4/11	1.615	8/13	1.857	6/7
1.133	2/15	1.375	3/8	1.625	5/8	1.867	13/15
1.143	1/7	1.385	5/13	1.636	7/11	1.875	7/8
1.154	2/13	1.400	2/5	1.643	9/14	1.889	8/9
1.167	1/6	1.417	5/12	1.667	2/3	1.900	9/10
1.182	2/11	1.429	3/7	1.692	9/13	1.909	10/11
1.200	1/5	1.444	4/9	1.700	7/10	1.917	11/12
1.214	3/14	1.455	5/11	1.714	5/7	1.923	12/13
1.222	2/9	1.462	6/13	1.727	8/11	1.929	13/14
1.231	3/13	1.467	7/15	1.733	11/15	1.933	14/15

**Example 1: UART\_PCLK = 14.7456 MHz, BR = 9600:** According to the provided algorithm  $DL_{est} = U\_CLK / (16 \times BR) = 14.7456 \text{ MHz} / (16 \times 9600) = 96$ . Since this  $DL_{est}$  is an integer number, DivAddVal = 0, MulVal = 1, DLM = 0, and DLL = 96.

**Example 2: UART\_PCLK = 12 MHz, BR = 115200:** According to the provided algorithm  $DL_{est} = U\_CLK / (16 \times BR) = 12 \text{ MHz} / (16 \times 115200) = 6.51$ . This  $DL_{est}$  is not an integer number and the next step is to estimate the FR parameter. Using an initial estimate of  $FR_{est} = 1.5$  a new  $DL_{est} = 4$  is calculated and  $FR_{est}$  is recalculated as  $FR_{est} = 1.628$ . Since  $FR_{est} = 1.628$  is within the specified range of 1.1 and 1.9, DivAddVal and MulVal values can be obtained from the attached look-up table.

The closest value for  $FR_{est} = 1.628$  in the look-up [Table 22–486](#) is FR = 1.625. It is equivalent to DivAddVal = 5 and MulVal = 8.

Based on these findings, the suggested UART setup would be: DLM = 0, DLL = 4, DivAddVal = 5, and MulVal = 8. According to [Equation 22–3](#), the UART's baud rate is 115384. This rate has a relative error of 0.16% from the originally specified 115200.

Comparison with [Table 22–485](#) shows that for this baud rate, several different combinations of parameters DLM, DLL, DivAddVal, and MulVal can produce the same actual baud rate.

## 6. Power optimization

---

The UART module has an asynchronous clock domain crossing, allowing the APB clock frequency to be independent from the Baud Generator clock frequency. This allows power saving by lowering the APB bus frequency while receiving and transmitting on the serial interface, with the same unchanged Baud Generator clock frequency.

Furthermore, when using the UART try to comply with the following guidelines:

- Operate at a low baud rate, when possible.
- When communicating at a low baud rate, you must reduce the U\_CLK accordingly.
- Independently from the baud rate, you must reduce the APB\_CLK if possible.
- Switch off the clocks when the device is not in use.
- Reduce the amount of interrupt routines.
- Use the FIFO for a more efficient data transfer.

## 1. Introduction

---

The LCD interface contains logic to interface to 6800 (Motorola) and 8080 (Intel) compatible LCD controllers with 4/8/16 bit modes. This module also supports a serial interface mode. The speed of the interface can be adjusted in software to match the speed of the connected LCD display.

This module has the following features:

- 4/8/16 bit parallel interface mode: 6800-series, 8080-series.
- Serial interface mode.
- Multiple frequencies for the 6800/8080 bus selectable to support high and low speed controllers.
- Supports polling the busy flag from LCD controller to off load the CPU from polling.
- Contains a 16 byte FIFO for sending control and data information to the LCD controller.
- Supports maskable interrupts.
- Supports DMA transfers.

## 2. General description

---

The LCD interface is compatible with the 6800 bus standard and the 8080 bus standard, with one address pin (RS) for selecting the data or instruction register.

The LCD interface makes use of a configurable clock (programmed in the CGU) to adjust the speed of the 6800/8080 bus to the speed of the connected peripheral.

## 2.1 Block diagram

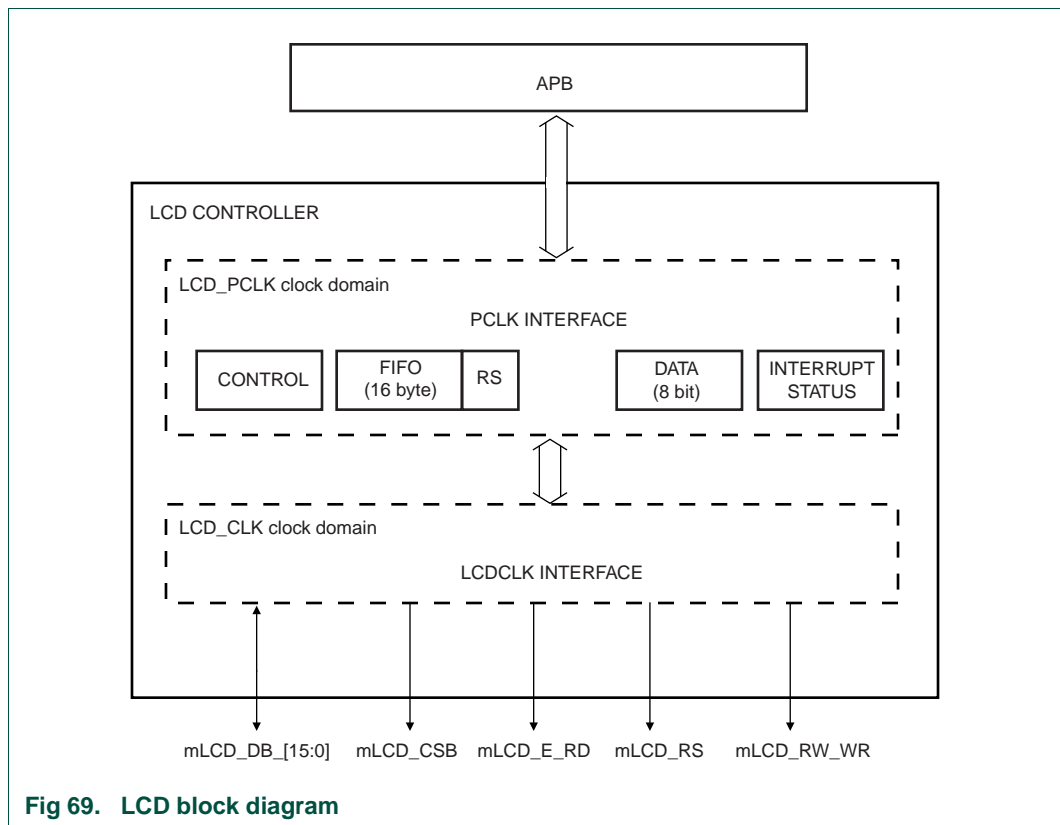

Fig 69. LCD block diagram

## 2.2 Interface description

### 2.2.1 Clock signals

Table 487. Clock signals of the LCD interface module

Clock name	Acronym	I/O	Source	Description
LCD_PCLK	PCLK	I	CGU	APB CLK
LCD_CLK	LCDCLK	I	CGU	Clock used for data and control flow towards the external LCD Controller

The LCD\_CLK is configurable to match the clock frequency of external LCD Controller.

### 2.2.2 External pin connections

Table 488. External signals of the LCD interface module

Name	Type (func)	Description
mLCD_CSB	O	Chip Select for external LCD-Controller. Default active HIGH.
mLCD_RS	O	Register Select (also seen as A0) '1' = Data, '0' = Instruction

**Table 488. External signals of the LCD interface module** ...continued

Name	Type (func)	Description
mLCD_RW_WR	O	Read Write / WRITE: Read/write in 6800 mode, Write in 8080 mode
mLCD_E_RD	O	Enable / Read: Enable in 6800 mode, Read in 8080 mode
mLCD_DB_[15:0]	I/O	Bi-directional data bus

### 2.2.3 Interrupt request signals

The LCD controller block provides one interrupt output. This interrupt has four possible functions: LCD FIFO EMPTY, LCD FIFO HALF EMPTY, LCD FIFO OVERRUN, LCD READ VALID (see [Section 23–5.1](#)). The valid function at any give time can be read from the LCD interface status register ([Table 23–490](#)).

### 2.2.4 Reset signals

The LCD interface is reset by a APB bus Reset.

2.2.5 LCD timing

(1) In 8-bit mode, the data D[7:0] is output on LCD\_DB[15:8] pins.

Fig 70. Timing diagram

### 3. Register overview

**Table 489. Register overview: LCD (register base address 0x1500 0400)**

Name	R/W	Address offset	Description	Reset Value
LCD_STATUS	R	0x000	Status register	0x0
LCD_CONTROL	R/W	0X004	Control register	0x0000 3CF0
LCD_INT_RAW	R	0X008	Interrupt Raw register	0X0000 0003
LCD_INT_CLEAR	W	0x00C	Interrupt Clear register	0x0
LCD_INT_MASK	R/W	0x010	Interrupt Mask Register	0x0000 000F
LCD_READ_CMD	W	0x014	Read Command register	0x0
LCD_INST_BYTE	R/W	0x020	Instruction Byte Register	0x0
LCD_DATA_BYTE	R/W	0x030	Data Byte Register	0x0
LCD_INST_WORD	W	0x040	Instruction Word register	0x0
LCD_DATA_WORD	W	0x080	Data Word register	0x0

### 4. Register description

#### 4.1 LCD interface Status Register

Read only. This register stores the interrupt status; the busy bit and the FIFO counter value.

**Table 490. LCD interface Status Register (LCD\_STATUS, address 0x1500 0400)**

Bit	Symbol	Access	Reset Value	Description
31:10	Reserved	-	-	Reserved
9:5	LCD_COUNTER	R	0x00000	current value of the FIFO counter. 0x00 means empty.
4	LCD_INTERFACE_BUSY	R	0x1	LCD interface is still reading the value from the controller
3	LCD_INT_READ_VALID	R	0x0	value read from the LCD controller is valid and not masked in the LCD_INT_MASK register
2	LCD_INT_FIFO_OVERRUN	R	0x0	value being written is larger than the FIFO can hold and not masked in the LCD_INT_MASK register
1	LCD_INT_FIFO_HALF_EMPTY	R	0x0	FIFO is less than half full (when LCD_counter < 8) and not masked in the LCD_INT_MASK register
0	LCD_INT_FIFO_EMPTY	R	0x0	FIFO is empty (LCD_counter = 0) and not masked in the LCD_INT_MASK register

#### 4.2 LCD interface Control register

Read/write. This register stores the control bits used by the LCD interface.

**Table 491. LCD interface Control register (LCD\_CONTROL, address 0x1500 404)**

Bit	Symbol	Access	Reset Value	Description
31:21	Reserved	-	-	Reserved
20	BYASYNC_RELCLK	R/W	0x0	Bypass the logic which assumes asynchronous relation between PCLK & LCDCLK
19	IF_16	R/W	0x0	Interface to 16 bit LCD-Controller. If set, overrides the IF (bit 3)
18	LOOPBACK	R/W	0x0	'0' = Normal Operation '1' = LCD Interface in Loopback mode
17	MSB_FIRST	R/W	0x0	8-bit mode: Don't care.  4-bit mode: '0' means that bits 3-0 will be transmitted first. '1' means that bits 7-4 will be transmitted first.  Serial mode: '0' means that bit 0 will be transmitted first. '1' means that bit 7 will be transmitted first.
16	INVERT_E_RD	R/W	0x0	Intel 8080 mode (MI = 0): '0' = E_RD output pin will be active low '1' = E_RD output pin will be active high  Motorola 6800 mode (MI = 1): '0' = E_RD output pin will be active high '1' = E_RD output pin will be active low
15	INVERT_CS	R/W	0x0	'1' = Chip select output will be active low '0' = Chip select output will be active high
14	BUSY_RS_VALUE	R/W	0x0	'0' = busy check will happen on RS = '0'. '1' = busy check will happen on RS = '1'. Don't care if BUSY_FLAG_CHECK = '0'
13:10	BUSY_BIT_NR	R/W	0xF	This 4 bit value stores the bit of the 6800/8080 bus which represents the busy flag. Don't care if BUSY_FLAG_CHECK = '0'
9	BUSY_VALUE	R/W	0x0	'0' = if the checked bit equals to '0' that the LCD controller is not busy. '1' = if the checked bit equals to '1' that the LCD controller is busy. Don't care if BUSY_FLAG_CHECK = '0'
8	BUSY_FLAG_CHECK	R/W	0x0	'0' will disable the busy-flag checking '1' will enable the busy-flag-checking
7:6	SERIAL_READ_POS	R/W	0x3	Parallel mode (PS = 0): Dont care Serial Mode (PS=1): '00xx' = Sampling done at the beginning of the cycle '01xx' -- Sampling done at 0.25 * cycle '10xx' -- Sampling done at 0.5 * cycle '11xx' -- Sampling done at 0.75 * cycle See <a href="#">Figure 23–71</a> .

**Table 491. LCD interface Control register (LCD\_CONTROL, address 0x1500 404) ...continued**

Bit	Symbol	Access	Reset Value	Description
5:4	SERIAL_CLK_SHIFT	R/W	0x3	Parallel mode (PS = 0): Don't care Serial Mode (PS=1): 'xx00' -- clock mode 0 'xx01' -- clock mode 1 'xx10' -- clock mode 2 'xx11' -- clock mode 3
3	IF (8bit/4bit)	R/W	0x0	'0' = put the LCD interface in 8 bit mode '1' = put the LCD interface in 4 bit mode. Do not care if PS = '1' Do not care if IF_16 = '1'
2	MI (Motorola 6800/Intel 8080)	R/W	0x0	'0' = put the LCD interface in 8080 mode. '1' = put the LCD interface in 6800 mode. Do not care if PS='1'
1	PS (Parallel/Serial)	R/W	0x0	'0' = put LCD interface in parallel mode '1' = put the LCD interface in serial mode
0	Reserved	R/W	0x0	Reserved

### 4.3 LCD interface Interrupt raw register

This register contains the status of the interrupts, without any masking.

**Table 492. LCD interface Interrupt Raw register (LCD\_INT\_RAW, address 0x1500 0408)**

Bit	Symbol	Access	Reset Value	Description
31:4	Reserved	-	-	Reserved
3	LCD_INT_READ_VALID_RAW	R	0x0	Is set when the value that has been read from the LCD controller is valid.
2	LCD_INT_OVERRUN_RAW	R	0x0	Is set when FIFO overrun occurs.
1	LCD_INT_FIFO_HALF_EMPTY_RAW	R	0x0	Is set when the FIFO is less than half full (when LCD_counter < 8)
0	LCD_INT_FIFO_EMPTY_RAW	R	0x0	Is set when the FIFO is empty (LCD_counter = 0)

### 4.4 LCD interface Interrupt Clear register

Write only. Writing to this register clears the selected interrupts.

**Table 493. LCD interface Interrupt Clear register (LCD\_INT\_CLEAR, address 0x1500 040C)**

Bit	Symbol	Access	Reset Value	Description
31:4	Reserved	-	0x0	Reserved
3	LCD_INT_READ_VALID_CLR	W	0x0	Clear Interrupt caused by Valid Read

**Table 493. LCD interface Interrupt Clear register (LCD\_INT\_CLEAR, address 0x1500 040C)**

Bit	Symbol	Access	Reset Value	Description
2	LCD_FIFO_OVERRUN_CLR	W	0x0	Clear Interrupt caused by FIFO Overrun
1	LCD_INT_FIFO_HALF_EMPTY_CLR	W	0x0	Clear Interrupt caused by FIFO Half Empty
0	LCD_INT_FIFO_EMPTY_CLR	W	0x0	Clear Interrupt caused by FIFO Empty

#### 4.5 LCD interface Interrupt Mask register

Read/write. This register contains the masking information for the interrupt. If a mask bit equals to `1' than that specific interrupt won't be used as a source for the IRQ to the CPU.

**Table 494. LCD interface Interrupt Mask register (LCD\_INT\_MASK, address 0x1500 0410)**

Bit	Symbol	Access	Reset Value	Description
31:4	Reserved	-	0x0	Reserved
3	LCD_READ_VALID_MASK	R/W	0x1	Interrupt mask for Valid Read
2	LCD_FIFO_OVERRUN_MASK	R/W	0x1	Interrupt mask for FIFO Overrun
1	LCD_FIFO_HALF_EMPTY_MASK	R/W	0x1	Interrupt mask for FIFO Half Empty
0	LCD_FIFO_EMPTY_MASK	R/W	0x1	Interrupt mask for FIFO Empty

#### 4.6 LCD interface Read Command register

Write only. Writing to this register will result in a read operation on the LCD Interface bus. A write to this register during a read operation will trigger a new read, and will discard the old.

Writing `0x00' will result in a read on the INST\_BYTE (see [Table 23–496](#)).

Writing `0x01' will result in a read in DATA\_BYTE (see [Table 23–497](#)).

If a read is finished (valid) the byte can be read in either LCD\_INST\_BYTE or LCD\_DATA\_BYTE.

**Table 495. LCD interface Read Command register (LCD\_READ\_CMD, address 0x1500 0414)**

Bit	Symbol	Access	Reset Value	Description
31:1	Reserved	-	-	Reserved
0	LCD_READ_COMMAND	W	0x0	'1' = read on the INST_BYTE '0' = read in DATA_BYTE

#### 4.7 LCD interface Instruction Byte register

Read/write. Writing to this register will write one byte into the FIFO, tagged as instruction.

Reading from this register will return the data read from the LCD controller. The data can be considered valid if the interrupt: LCD\_INT\_DATA\_VALID occurred, or if bit `LCD\_INTERFACE\_BUSY' reads `0'.

**Table 496. LCD interface Instruction Byte register (LCD\_INST\_BYTE, address 0x1500 0420)**

Bit	Symbol	Access	Reset Value	Description
31:8 / 31:16	Reserved	-	-	16 bit mode = 31:16 Reserved 8 bit mode = 31:8 Reserved
15:0 / 7:0	INST_BYTE	R/W	0x00	16 bit mode = 15:0 Instruction 8 bit mode = 7:0 Instruction

#### 4.8 LCD interface Data Byte register

Read/write. Writing to this register will write one byte into the FIFO, tagged as data.

Reading from this register will return the data read from the LCD controller. The data can be considered valid if the interrupt LCD\_INT\_DATA\_VALID occurred, or if bit 'LCD\_INTERFACE\_BUSY' reads '0'

**Table 497. LCD interface Data Byte register (LCD\_DATA\_BYTE, address 0x1500 0430)**

Bit	Symbol	Access	Reset Value	Description
31:8 / 31:16	Reserved	-	-	16 bit mode = 31:16 Reserved 8 bit mode = 31:8 Reserved
15:0 / 7:0	DATA_BYTE	R/W	0x00	16 bit mode = 15:0 Data 8 bit mode = 7:0 Data

#### 4.9 LCD interface Instruction Word register

Word write only. Writing to this register writes the 32-bit value into the FIFO, tagged as instruction. Burst writes are allowed. The LSB byte of the word will be transmitted out of the FIFO first.

**Table 498. LCD interface Instruction Word register (LCD\_INST\_WORD, address 0x1500 0440)**

Bit	Symbol	Access	Reset Value	Description
31: 0	INST_WORD	W	0x0	32 bit Instruction Word

#### 4.10 LCD interface Data Word register

Word write only. Writing to this register writes the 32-bit value into the FIFO, tagged as data. Burst writes are allowed. The LSB byte of the word will be transmitted out of the FIFO first.

**Table 499. LCD interface Data Word Register (LCD\_DATA\_WORD, address 0x1500 0480)**

Bit	Symbol	Access	Reset Value	Description
31: 0	DATA_WORD	W	0x0	32 bit Data Word

## 5. Functional description

### 5.1 Interrupt generation

An interrupt is generated on the following occasions:

- When the FIFO is empty (LCD\_FIFO\_EMPTY).
- When the FIFO is half empty (LCD\_FIFO\_HALF\_EMPTY).
- When the FIFO is overrun (LCD\_FIFO\_OVERRUN).
- When the requested instruction/data register is valid (LCD\_READ\_VALID).

Any of these interrupts can be masked individually to keep them from generating an interrupt to the CPU, by using the LCD\_INT\_MASK register. The interrupts after masking can be read in the LCD\_STATUS register. Writing a `1` in the mask register will mask the interrupt. The status of the interrupts without masking can be read in the `LCD\_INT\_RAW` register.

## 5.2 Clearing the interrupts

An interrupt can be cleared by writing a `1` to the respective bit in the LCD\_INT\_CLR register. If the interrupt has not been solved, for instance the FIFO is still empty, this will re-set the interrupt, when not masked.

## 5.3 Using DMA flow control

All data transfers towards the LCD interface can be done using the DMA and the corresponding flow control, reducing CPU interrupting.

The DMA has the ability to transfer blocks of data from memory and the LCD FIFO while checking the FIFOLEVEL flow control before sending data. This way data will only be sent when the LCD interface has space left in its local FIFO.

This construction allows much larger blocks of data to be transported to the LCD interface than the maximal 16 bytes of the FIFO at a time.

If the external LCD controller supports it, a single enable command to the DMA controller may refresh the complete LCD screen, making the LCD-controller a very low CPU-intensive piece of hardware.

It requires a single DMA channel to transfer data to the LCD interface. If a linked-list must be supported, then two sequential channels are required. See the DMA chapter of this document for more info.

LCD-reading is not supported with DMA flow control.

## 6. Power optimization

---

To reduce the power consumption, this module uses a gated clock. The clock coming from the CGU will be disabled when the module is not in use.

## 7. Programming guide

---

### 7.1 Resetting the external LCD controller

A GPIO pin or the system reset can be used to act as a reset signal for the external LCD controller. In some cases a simple instruction to the controller is enough to perform the reset.

## 7.2 FIFO

A 16 byte write FIFO (First In First Out memory) is implemented in the LCD interface which will store both instructions and data. This way the CPU can write multiple bytes or words to the LCD interface instead of just one and doesn't have to wait for the LCD controller to finish for a new write action.

Information to the LCD controller can be written in the LCD\_INST\_WORD or LCD\_DATA\_WORD register. If the total amount of data written is bigger than the FIFO can store, the 'FIFO\_overn' interrupt will be set, and the last byte or word will not be written into the FIFO.

If a word is written into the FIFO, the LSB byte (bits 7-0) will be put on the data pins first.

A status pin indicating that the FIFO is at least half empty is connected at top-level, so the Simple DMA controller can decide when it is allowed to transfer data and when it is not allowed.

## 7.3 Operational modes

The LCD Interface has four modes for outputting data: 16-bit mode, 8-bit mode, 4-bit mode and serial-mode.

### 7.3.1 16-bit mode

The LCD\_CONTROL register also has IF\_16 bit to enable 16-bit mode. When this bit is set, the IF bit becomes don't care. When IF\_16 bit is reset, then IF bit decides between 8-bit or 4-bit mode.

The FIFO remains 8-bit wide. The LDCCLK interface state machine consecutively reads 2 bytes from the FIFO. To announce the consecutive read to the PCLK interface state machine, the 'continue FIFO' signal was added. This way the 16-bit functionality is added to the hardware. It is backwards compatible. So in 8-bit mode, the LCD interface writes (to the outside world) 1 byte, and in 16-bit mode it writes 2 bytes. Similarly on a READ action (LCD-Interface reading from external LCD-Controller), 8-bit data is read in 8-bit mode, and 16-bit data is read in 16-bit mode.

### 7.3.2 8-bit mode

The most significant byte of the databus is used in 8-bit mode. It means the [7:0] bits of the databus of the external controller should be connected to the [15:8] bits of the databus interface of the LCD interface.

At each shift of the FIFO, the last byte inside the FIFO will be put on the data pins, and pin LCD\_RS will indicate if the data is an instruction or data value.

In read mode the data on pins LCD\_DB[15:8] will be sampled by the LCD interface.

### 7.3.3 4-bit mode

The most significant nibble of the databus is used in 4-bit mode. It means the [3:0] bits of the databus of external controller should be connected to the [15:12] bits of the databus interface of the LCD interface.

At each shift of the FIFO, the last byte from the FIFO will be split, where the order depends on the 'MSB\_first' from the control register. When set to '1', bit 7-4 from the FIFO byte will be put first, or read first, at the data pins, and then bit 3-0. When set to '0' bits 3-0 will be written or read first, and then bits 7-4.

### 7.3.4 Serial mode

At each shift of the FIFO, the last FIFO byte will be split in 8 separate bits and be put on data pin LCD\_DB14 (serial data in) and LCD\_DB15 (serial data out), where the bit-order depends on the 'MSB\_first' from the control register.

When set to '0', then first bit 0 and last bit 7 will be written/read first, else the order is from 7 down to 0.

Signal LCD\_RS is included for each 8 bits and indicates an instruction or data. Not all controllers require this signal in serial mode, but can be used if required.

## 7.4 Writing data

There are 2 modes by which information can be sent out on the 6800/8080 bus. These can be addressed, by using the following registers:

### LCD\_INST\_BYTE/LCD\_INST\_WORD

Writing to one of these registers will add the contents to the FIFO, tagged as instruction.

- To write a word into the FIFO: write the word to register LCD\_INST\_WORD. The LSB byte of the word will be transmitted first out of the FIFO.
- To write a byte (8-bit mode) or half-word (16-bit mode) into the FIFO: write the byte(8-bit mode) or half-word(16-bit mode) to register LCD\_INST\_BYTE.

**Remark:** The separation of bytes and words is necessary, because the APB assumes all data to be 32 bit wide.

### LCD\_DATA\_BYTE / LCD\_DATA\_WORD

Writing to these registers will add the contents to the FIFO, tagged as data.

To write a word into the FIFO: write the word to address: LCD\_DATA\_WORD. The LSB byte of the word will be transmitted first out of the FIFO.

To write a byte(8-bit mode) or half-word(16-bit mode) into the FIFO: write the byte(8-bit mode) or half-word(16-bit mode) to register LCD\_DATA\_BYTE.

## 7.5 Reading data

Reads from the LCD controller are quite rare. Normally only writes are performed to a LCD controller. Therefore a simple double byte register is used to store the byte / half-word that has been read from the 6800/8080 bus.

The LCD controller is a slow peripheral. When the CPU requests information from the 6800/8080 bus, it will not be available directly. To read the data register or the instruction register, the CPU has to wait a while before the data becomes valid.

The read procedure is as follows:

1. Write the following in the LCD\_READ\_CMD register:
  - 0x0' for initiating a read on INST\_BYTE (RS=0)
  - 0x1' for initiating a read on DATA\_BYTE (RS=1)
2. Wait until an IRQ arrives, and check the `LCD\_read\_valid' bit of the STATUS register  
or  
keep polling the LCD\_INTERFACE\_BUSY bit of the STATUS register. `0' means valid.
3. If the returned value is valid, the byte can be read from the LCD\_INST\_BYTE or LCD\_DATA\_BYTE register. A write to LCD\_READ\_CMD will initiate a new read on the LCD bus.

If the LCD\_INST\_BYTE or LCD\_DATA\_BYTE register is read, the LCD\_INTERFACE\_BUSY bit of the CONTROL register stays logical `0' until a new read is started.

## 7.6 Combined Writing and reading data

A read operation can be performed at any time. The read-request is stored (queued), and as soon as the write FIFO is empty, the read operation will be executed. Only one read request is stored, so if there were multiple read requests (which is considered invalid), the last one will be executed.

Note: A write operation after a read operation, which is still queued or has not completed its cycle, is considered invalid. The read operation will be discarded or aborted and the LCD interface will enter or stay (if the LCD interface did not start reading yet) in write mode. The written value is stored in the FIFO as being a regular write transfer, and the LCD interface will proceed normally, without executing the read command.

## 7.7 Using wait states

The LCD controller does not support waitstates. If the LCD bus needs to be made slower, it is best to reduce the LCD\_CLK speed in the CGU.

## 7.8 Serial mode

The LCD interface can be put in serial mode by setting bit `PS' of LCD\_CONTROL register to `1'.

### 7.8.1 Serial writes

In this mode, the FIFO will be used to shift the data on a bit-by-bit basis on pin LCD\_DB15 of the LCD interface. The `MSB\_first' bit of the control register controls if the MSB or LSB bit is transmitted first:

- `0' to select LSB first (first bit 0, then 1,2,3,4,5,6,7).
- `1' to select if the serial data is transmitted with MSB first (so first bit 7, then 6,5,4,3,2,1,0)

This is depending on how the LCD controller accepts serial information.

If the FIFO runs empty, the LCD\_FIFO\_empty bit of the raw-status interrupt register will be set, and the serial clock output will be disabled, until new data is available in the FIFO.

The LCD\_RS output can be used to select the data or instruction register of the LCD controller.

**7.8.2 Serial reads**

Serial reading uses the same commands as parallel reading.

Reading the serial data is done on pin LCD\_DB14 of the 6800/8080 bus. The 'MSB\_first' bit controls which bit is sampled first:

- '0' to select that the first sampled bit will be stored in the LSB bit
- '1' to select that the first sampled bit will be stored in the MSB bit.

Eight clock cycles are generated on the serial clock, and the serial input will be sampled for 8 cycles.

Now the information in the LCD\_DATA\_BYTE register is valid and can be read.

**7.8.3 Serial clock timing**

The serial output clock 'SCL' can be set to four modes to comply to the specifications of the LCD controller. Each mode is a 25% shift of the previous mode. The clock mode is set by writing to the 'serial\_clk\_shift' location of the control register.

For reading, register location 'serial\_read\_pos' of the control register determines at which position the data is sampled by the LCD interface. See [Figure 23–71](#).

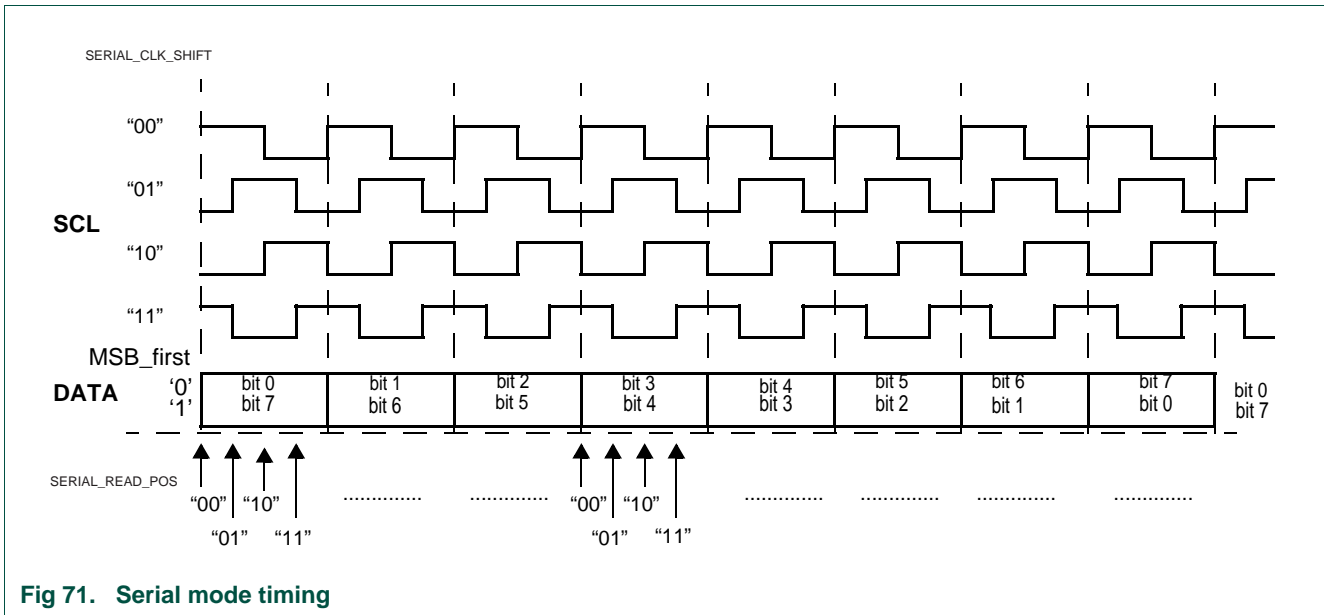

Fig 71. Serial mode timing

**7.9 Checking the busy flag of the LCD controller**

Most LCD controllers contain a status register with a bit that represents the busy flag. If available, this flag has to be polled before a read or write can be performed from or to the LCD controller.

To off-load the CPU from polling the LCD controller before each access, an option is included that the LCD interface takes over this polling for data read, data write and instruction write accesses.

To enable the busy-flag checking, set the following bits in the CONTROL register:

- **BUSY\_FLAG\_CHECK'**: set to `1' to enable the busy-flag-checking
- **BUSY\_BIT\_NR'**: Set which bit number has to be checked for the busy flag. Don't care if **BUSY\_FLAG\_CHECK** = `0'
- **BUSY\_RS\_VALUE'**: Set which address (RS value) has to be checked for the busy flag.
  - when `0' then register belonging to RS='0' will be checked.
  - when `1' the register belonging to RS='1' will be checked.
 Don't care if **BUSY\_FLAG\_CHECK** = `0'
- **BUSY\_VALUE'**: Set if a logic `0' or `1' represents the busy flag. Don't care if **BUSY\_FLAG\_CHECK** = `0'

Note: Reading the register from the LCD controller set by **BUSY\_RS\_VALUE** will return the value of that register, without checking for the busy-flag first.

The busy-flag-checking can only be used if one of the two LCD controller registers have a bit that represents the `busy' value. If this bit is not available, the busy-flag-checking feature has to be disabled and a slower clock has to be used to ensure reading or writing a valid value.

## 7.10 Loop back mode

Setting the register `LOOPBACK' of the CONTROL register to `1', will set the LCD interface in loop back-mode.

Internally, the LCD data output is connected to the LCD data input. The programmer can test correct behavior of the LCD interface, by doing the following:

- Place the LCD interface in parallel, 8-bit mode
- Write a single byte to the LCD\_DATA\_BYTE register
- Write `0x01' to the LCD\_READ\_CMD register to request a bus read
- Poll the status bit, or wait for the `valid' interrupt (if MASK is cleared)
- If valid, read the byte from LCD\_DATA\_BYTE register
- Compare this value with the written value

To ensure correctness of the test, perform the above a couple of times, with different values.

## 7.11 Clock relation PCLK and LCDCLK

The LCDCLK and the PCLK (see [Table 23–487](#)) can be totally independent from each other. The PCLK logic samples the LCDCLK and uses this as a timing reference. Internally the LCDCLK is converted to pulses at each rising edge of the PCLK.

The PCLK should run at least 2 times as fast as the LCDCLK. The LCDCLK should have the `clock\_stretching' option enabled when it is configured.

Every 5 LCDCLK cycles means one LCD bus cycle.

If Busy flag checking is enabled each write will take 10 cycles, since each write is accompanied by a read.

### 7.12 MSB\_FIRST bit of Control Register

In 8-bit mode, value of MSB\_FIRST is do not care. In 8-bit mode, it always works as LSB\_FIRST. This feature was there because the fifo is 8-bit wide, and while sending data out, it can be programmed which bit / nibble of that 8 bit should go out first. Now although the databus was extended to 16-bit wide, the fifo width was kept as it was = 8-bit. Hence in 8-bit mode, there is no extra facility. Whatever is available at the end of FIFO, will come out first. And the FIFO is fed from its input side as LSB\_FIRST protocol. (LS-Byte of the 32-bit word written to IP via APB bus.).

## 1. Introduction

---

The LPC315x contains two I<sup>2</sup>C Master / Slave interfaces (I<sup>2</sup>C).

### 1.1 Features

This module has the following features:

- **I<sup>2</sup>C0-bus interface:** The I<sup>2</sup>C0-bus interface is a standard I<sup>2</sup>C-compliant bus interface with open-drain pins. This interface supports functions described in the I<sup>2</sup>C-bus specification for speeds up to 400 kHz. This includes multi-master operation and allows powering off this device in a working system while leaving the I<sup>2</sup>C-bus functional.
- **I<sup>2</sup>C1-bus interface:** The I<sup>2</sup>C1-bus interface is internally connected to the analog die and used to access the analog die registers for the audio codec with the stereo ADC and DAC, the RTC, the PSU, the Li-ion charger, and the charge pump. All blocks in the analog die behave like one I<sup>2</sup>C slave device to the I<sup>2</sup>C1 interface. The 7 bit slave address is 0x0C (0001100). See [Section 30–3](#) for details on the I<sup>2</sup>C1 protocol.
- Supports normal mode (100 kHz SCL) and fast mode (400 kHz SCL).
- Interrupt support.
- Supports DMA transfers (single).
- Four modes of operation:
  - Master transmitter
  - Master receiver
  - Slave transmitter
  - Slave receiver

## 2. General description

---

There are two I<sup>2</sup>C interfaces in the LPC315x. These I<sup>2</sup>C blocks can be configured as a master, multimaster or slave supporting clock rates up to 400 kHz. The I<sup>2</sup>C blocks also support 7 or 10 bit addressing. Each has a four word FIFO for both transmit and receive. An interrupt signal is available from each block.

There is a separate slave transmit FIFO. The slave transmit FIFO (TXS) and its level are only available when the controller is configured as a Master/Slave device and is operating in a multi-master environment. Separate TX FIFOs are needed in a multi-master because a controller might have a message queued for transmission when an external master addresses it to become a slave-transmitter, a second source of data is needed.

A typical I<sup>2</sup>C-bus configuration is shown in [Figure 24–72](#). Depending on the state of the direction bit (r/w), two types of data transfers are possible on the I<sup>2</sup>C-bus:

Data transfer from a master transmitter to a slave receiver. The first byte transmitted by the master is the slave address. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte.

Data transfer from a slave transmitter to a master receiver. The first byte (the slave address) is transmitted by the master. The slave then returns an acknowledge bit. Next follows the data bytes transmitted by the slave to the master. The master returns an acknowledge bit after all received bytes other than the last byte. At the end of the last received byte, a “not acknowledge” is returned. The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a repeated START condition. Since a repeated START condition is also the beginning of the next serial transfer, the I<sup>2</sup>C-bus will not be released.

Each of the I<sup>2</sup>C interfaces on the LPC315x contains a four byte FIFO, allowing more data to be transferred before additional software attention is needed.

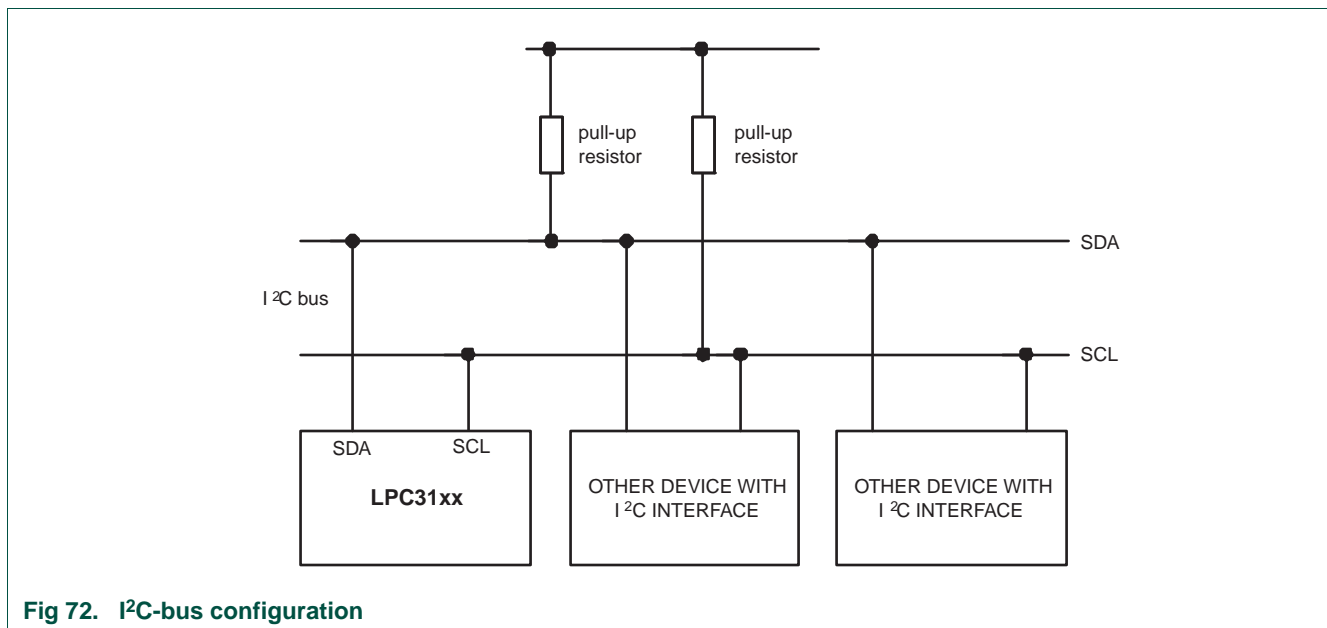

Fig 72. I<sup>2</sup>C-bus configuration

## 2.1 Block diagram

The ARM Peripheral Bus interface (APB) provides a communication link between the CPU and the I2C controller. The shift register handles serializing/de-serializing data and counting bits of a byte. The Rx and Tx Control blocks count bytes and handling byte acknowledgement. The Master and Slave control blocks can each enable or disable the Rx and Tx control and also handle transferring data between the shift register and the Rx and Tx FIFOs. SDAOUT is driven either by shift register data, acknowledge signals, or the Master control for creating START or STOP conditions. SCLOUT is driven by the Master control generating a clock or by the Slave control extending the clock of an external master.

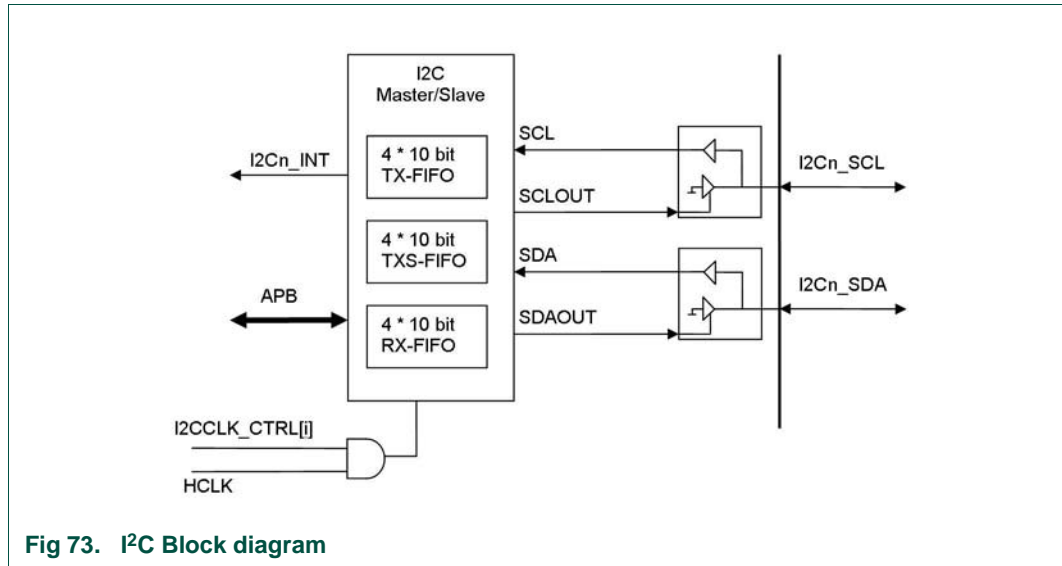

Fig 73. I<sup>2</sup>C Block diagram

## 2.2 Interface description

### 2.2.1 Clock signals

Table 500. Clock signals of the I<sup>2</sup>C Master/Slave Interface

Clock name	Acronym	I/O	Source/destination	Description
I2C_SCL0/1	SCL	I/O	Pin	Serial Clock. This is the current value of the I2C serial clock input from a pad.
I2C0/1_PCLK	HCLK	I	CGU	APB Clock. The single clock domain reference for the I2C. This signal is un-buffered.

### 2.2.2 Pin connections

Table 501. Signals to pins of the IC for the I<sup>2</sup>C Master/Slave Interface

Name	Type	Reset value	Description	Pad connection
I2C_SCL0	I/O	-	Serial Clock. This is the current value of the I2C serial clock input from a pad.	pinned out
I2C_SDA0	I/O	-	Serial Data. This is the current value of the I2C serial data line input from a pad.	pinned out
I2C_SCL1	I/O	-	Serial Clock. This is the current value of the I2C serial clock.	internally connected to analog die
I2C_SDA1	I/O	-	Serial Data. This is the current value of the I2C serial data line input.	internally connected to analog die

**Table 502. Auxiliary pin signals of the I<sup>2</sup>C Master/Slave interface**

Name	Type	Reset value	Description
SCLOUT	O	1	Transmitter Clock. This drives the external serial clock line low or allows it to float high.
SDAOUT	O	1	Transmitter Data. This drives the external serial data line low or allows it to float high.
SCANTESTMODE	I	0	Scan test enabled. This signal is active during scan testing to avoid bus contention on the PD bus.

### 2.2.3 Interrupt requests

The I2C0/1 interfaces produce one (active LOW) interrupt each. The reason for the interrupt is encoded in the status register (STS). There are several possible interrupt types: transfer completed, arbitration failure, missing acknowledge, need more data, Tx FIFO has room for more data, or data has been received. The interrupt signal NINTR is a combination of the status register bits and the enables in the control register.

### 2.2.4 Reset signals

The I2C0/1 internal registers and FIFOs are reset by a PNRES signal from the CGU.

### 2.2.5 DMA flow control transfer signals

The I2C Master/Slave interface supports single DMA transfers. The DMA request line is connected with the interrupt line (NINTR) when DMA is used. For DMA operations, the proper interrupts should be unmasked in the control register (CTL).

## 3. Register overview

Each I<sup>2</sup>C interface contains the registers shown in [Table 24–503](#) and [Table 24–504](#). More detailed descriptions follow.

**Table 503. Register overview: I2C0 registers (base address 0x1300 A000)**

Name	Access	Address offset	Description
I2C0_RX	RO	0x00	I2Cn RX Data FIFO
I2C0_TX	WO	0x00	I2Cn TX Data FIFO
I2C0_STAT	RO	0x04	I2Cn Status Register
I2C0_CTRL	R/W	0x08	I2Cn Control Register
I2C0_CLK_HI	R/W	0x0C	I2Cn Clock Divider high
I2C0_CLK_LO	R/W	0x10	I2Cn Clock Divider low
I2C0_ADR	R/W	0x14	I2Cn Slave Address
I2C0_RXFL	RO	0x18	I2Cn Rx FIFO level
I2C0_TXFL	RO	0x1C	I2Cn Tx FIFO level
I2C0_RXB	RO	0x20	I2Cn Number of bytes received
I2C0_TXB	RO	0x24	I2Cn Number of bytes transmitted
I2C0_S_TX	WO	0x28	Slave Transmit FIFO
I2C0_S_TXFL	RO	0x2C	Slave Transmit FIFO level

**Table 504. Register overview: I2C1 registers (base address 0x1300 A400)**

Name	Access	Address offset	Description
I2C1_RX	RO	0x00	I2Cn RX Data FIFO
I2C1_TX	WO	0x00	I2Cn TX Data FIFO
I2C1_STAT	RO	0x04	I2Cn Status Register
I2C1_CTRL	R/W	0x08	I2Cn Control Register
I2C1_CLK_HI	R/W	0x0C	I2Cn Clock Divider high
I2C1_CLK_LO	R/W	0x10	I2Cn Clock Divider low
I2C1_ADR	R/W	0x14	I2Cn Slave Address
I2C1_RXFL	RO	0x18	I2Cn Rx FIFO level
I2C1_TXFL	RO	0x1C	I2Cn Tx FIFO level
I2C1_RXB	RO	0x20	I2Cn Number of bytes received
I2C1_TXB	RO	0x24	I2Cn Number of bytes transmitted
I2C1_S_TX	WO	0x28	Slave Transmit FIFO
I2C1_S_TXFL	RO	0x2C	Slave Transmit FIFO level

## 4. Register description

### 4.1 I2Cn RX Data FIFO register

The RX FIFO may be cleared via a soft reset, by setting bit 8 in the I2Cn\_CTRL register.

When operating as a master-receiver, the TX\_FIFO must be written for proper operation. When operating as a master-receiver the controller ignores bits [7:0] in the TX\_FIFO register. The master-receiver must write a (dummy) byte to the TX\_FIFO for each byte it expects to receive in the RX\_FIFO. The first dummy byte triggers the clock sequence to transfer data from the slave transmitter. Each dummy byte that follows has a dual purpose, it acknowledges reception of the previous byte and triggers the clock sequence to transfer the next byte from the slaver transmitter. If the master-receiver sets the STOP\_bit (9) (to signal the end of a receive) or sets the START\_bit (8) (to cause a RESTART condition), then the last byte read from the slave is not acknowledged. That is, the last byte of a master-receiver does not acknowledge by writing a dummy value to the TX\_FIFO register.

If the RX FIFO is read while empty, a DATA ABORT exception is generated.

**Table 505. I2Cn RX Data FIFO (I2C0\_RX - 0x1300 A000, I2C1\_RX - 0x1300 A400)**

Bit	Symbol	Description	Reset value
31:8	-	Reserved	-
7:0	RxDData	Receive FIFO data bits 7:0	N/A

### 4.2 I2Cn TX Data FIFO register

The TX FIFO may be cleared via a soft reset, by setting bit 8 in the I2Cn\_CTRL register.

If the controller is configured as a Master/Slave and is operating in a multi-master environment, then only master-transmit data should be written to I2Cn\_TX, slave transmit data should be written to I2Cn\_S\_TX.

If the TX FIFO is written to while full a DATA ABORT exception is generated.

**Table 506. I2Cn TX Data FIFO (I2C0\_TX - 0x1300 A000, I2C1\_TX - 0x1300 A400)**

Bit	Symbol	Description	Reset value
31:10	-	Reserved	-
9	STOP	0 = Do not issue a STOP condition after transmitting this byte 1 = Issue a STOP condition after transmitting this byte.	NA
8	START	0 = Do not Issue a START condition before transmitting this byte 1 = Issue a START condition before transmitting this byte.	NA
7:0	TxDData	Transmit FIFO data bits 7:0	NA

### 4.3 I2Cn Status register

The status is a read-only register that provides status information on the TX and RX blocks as well as the current state of the external buses. A soft reset will clear the status register with the exception of the TFE and RFE bits, which will be set, and the SCL and SDA bits, which continue to reflect the state of the bus pins.

**Table 507. I2Cn Status register (I2C0\_STAT - 0x1300 A004, I2C1\_STAT - 0x1300 A404)**

Bit	Symbol	Description	Reset value
31:14	-	Reserved	-
13	TFES	Slave Transmit FIFO Empty. Slave TFE is set when the slave TX FIFO is empty and is cleared when the slave TX FIFO contains valid data. 0 = TX FIFO is not empty. 1 = TX FIFO is empty	1
12	TFFS	Slave Transmit FIFO Full Slave TFF is set when the slave TX FIFO is full and is cleared when the slave TX FIFO is not full. 0 = Slave TX FIFO is not full. 1 = SlaveTX FIFO is full	0
11	TFE	Transmit FIFO Empty. TFE is set when the TX FIFO is empty and is cleared when the TX FIFO contains valid data. 0 = TX FIFO contains valid data. 1 = TX FIFO is empty	1
10	TFF	Transmit FIFO Full. TFF is set when the TX FIFO is full and is cleared when the TX FIFO is not full. 0 = TX FIFO is not full. 1 = TX FIFO is full	0
9	RFE	Receive FIFO Empty. RFE is set when the RX FIFO is empty and is cleared when the RX FIFO contains valid data. 0 = RX FIFO contains data. 1 = RX FIFO is empty	1

Table 507. I2Cn Status register (I2C0\_STAT - 0x1300 A004, I2C1\_STAT - 0x1300 A404)

Bit	Symbol	Description	Reset value
8	RFF	Receive FIFO Full. This bit is set when the RX FIFO is full and cannot accept any more data. It is cleared when the RX FIFO is not full. If a byte arrives when the Receive FIFO is full, the SCL is held low until the ARM reads the RX FIFO and makes room for it.  0 = RX FIFO is not full 1 = RX FIFO is full	0
7	SDA	The current value of the SDA signal.	NA
6	SCL	The current value of the SCL signal.	NA
5	ACTIVE	Indicates whether the bus is busy. This bit is set when a START condition has been seen. It is cleared when a STOP condition is seen.	0
4	DRSI	Slave Data Request Interrupt. Once a transmission is started, the transmitter must have data to transmit as long as it isn't followed by a stop condition or it will hold SCL low until more data is available. The Slave Data Request bit is set when the slave transmitter is data-starved. If the slave TX FIFO is empty and the last byte transmitted was acknowledged, then SCL is held low until the ARM core writes another byte to transmit. This bit is cleared when a byte is written to the slave Tx FIFO.  0 = Slave transmitter does not need data. 1 = Slave transmitter needs data.	NA
3	DRMI	Master Data Request Interrupt. Once a transmission is started, the transmitter must have Data to transmit as long as it isn't followed by a stop condition or it will hold SCL low until more data is available. The Master Data Request bit is set when the master transmitter is data-starved. If the master TX FIFO is empty and the last byte did not have a STOP condition flag, then SCL is held low until the ARM core writes another byte to transmit. This bit is cleared when a byte is written to the master TX FIFO.  0 = Master transmitter does not need data. 1 = Master transmitter needs data.	0

**Table 507. I2Cn Status register (I2C0\_STAT - 0x1300 A004, I2C1\_STAT - 0x1300 A404)**

Bit	Symbol	Description	Reset value
2	NAI	No Acknowledge Interrupt. After every byte of data is sent, the transmitter expects an acknowledge from the receiver. This bit is set if the acknowledge is not received. It is cleared when a byte is written to the master TX FIFO.  0 = Last transmission received an acknowledge. 1 = Last transmission did not receive an acknowledge.	0
1	AFI	Arbitration Failure Interrupt. When transmitting, if the SDA is low when SDAOUT is high, then this I2C has lost the arbitration to another device on the bus. The Arbitration Failure bit is set when this happens. It is cleared by writing a '1' to bit 1 of the status register.  0 = No arbitration failure on last transmission. 1 = Arbitration failure occurred on last transmission.	NA
0	TDI	Transaction Done Interrupt. This flag is set if a transaction completes successfully. It is cleared by writing a '1' to bit 0 of the status register. It is unaffected by slave transactions.  0 = Transaction has not completed. 1 = Transaction completed.	0

#### 4.4 I2Cn Control register

The CTL register is used to enable interrupts and reset the I<sup>2</sup>C state machine.

Note that the DMA request line is connected with the interrupt line when DMA is used. For DMA operations, the proper interrupts should be unmasked in the control register.

**Table 508. I2Cn Control register (I2C0\_CTRL - 0x1300 A008, I2C1\_CTRL - 0x1300 A408)**

Bit	Symbol	Description	Reset value
31:11	-	Reserved	-
10	TFFSIE	Slave Transmit FIFO Not Full Interrupt Enable. This enables the Slave Transmit FIFO Not Full interrupt to indicate that the more data can be written to the slave transmit FIFO. Note that this is not full.  0 = Disable the TFFSI. 1 = Enable the TFFSI.	0
9	SEVEN	Seven-bit slave address. This bit is selects 7-bit or 10-bit slave address operation. 0 = Use 7-bit slave addressing, bits [6:0] in address register. 1 = Use 10-bit slave address. Note: Performing a Soft Reset clears this bit to 0. Use 7-bit slave addressing.	0

Table 508. I2Cn Control register (I2C0\_CTRL - 0x1300 A008, I2C1\_CTRL - 0x1300 A408)

Bit	Symbol	Description	Reset value
8	RESET	Soft Reset. On a soft reset, the TX and RX FIFOs are flushed, STS register is cleared, and all internal state machines are reset to appear idle, and clears bit 9 forcing 7-bit slave addressing. The I2Cn_CLK_LO, I2Cn_CLK_HI, I2Cn_CTRL, and I2Cn_ADR registers are NOT modified by a soft reset. 0 = No effect 1 = Reset the I <sup>2</sup> C to idle state. Self clearing.	0
7	TFFIE	Transmit FIFO Not Full Interrupt Enable. This enables the Transmit FIFO Not Full interrupt to indicate that more data can be written to the transmit FIFO. Note that this is not full. It is intended help the ARM Write to the I <sup>2</sup> C block only when there is room in the FIFO to accept it and do this without polling the status register. 0 = Disable the TFFI. 1 = Enable the TFFI.	0
6	RFDAIE	Receive FIFO Data Available Interrupt Enable. This enables the DAI interrupt to indicate that data is available in the receive FIFO (i.e. not empty). 0 = Disable the DAI. 1 = Enable the DAI.	0
5	RFFIE	Receive FIFO Full Interrupt Enable. This enables the Receive FIFO Full interrupt to indicate that the receive FIFO cannot accept any more data. 0 = Disable the RFFI. 1 = Enable the RFFI.	0
4	DRSIE	Data Request Slave Transmitter Interrupt Enable. This enables the DRSI interrupt which signals that the slave transmitter has run out of data and the last byte was acknowledged, so the SCL line is being held low. 0 = Disable the DRSI interrupt. 1 = Enable the DRSI interrupt.	NA
3	DRMIE	Data Request Master Transmitter Interrupt Enable. This enables the DRMI interrupt which signals that the master transmitter has run out of data, has not issued a Stop, and is holding the SCL line low. 0 = Disable the DRMI interrupt. 1 = Enable the DRMI interrupt.	0

Table 508. I2Cn Control register (I2C0\_CTRL - 0x1300 A008, I2C1\_CTRL - 0x1300 A408)

Bit	Symbol	Description	Reset value
2	NAIE	Transmitter No Acknowledge Interrupt Enable. This enables the NAI interrupt signalling that transmitted byte was not acknowledged. 0 = Disable the NAI. 1 = Enable the NAI.	0
1	AFIE	Transmitter Arbitration Failure Interrupt Enable. This enables the AFI interrupt which is asserted during transmission when trying to set SDA high, but the bus is driven low by another device. 0 = Disable the AFI. 1 = Enable the AFI.	NA
0	TDIE	Transmit Done Interrupt Enable. This enables the TDI interrupt signalling that this I <sup>2</sup> C issued a stop condition. 0 = Disable the TDI interrupt. 1 = Enable the TDI interrupt.	0

#### 4.5 I2Cn Clock Divider High register

The I2Cn\_CLK\_HI register holds a terminal count for counting I2Cn\_PCLK cycles to create the high period of the slower I<sup>2</sup>C serial clock, SCL. When reset, the clock divider will be set to run at its reset value.

Table 509. I2Cn Clock Divider High (I2C0\_CLK\_HI - 0x1300 A00C, I2C1\_CLK\_HI - 0x1300 A40C)

Bit	Symbol	Description	Reset value
31:10	-	Reserved	-
9:0	CLK_DIV_HI	Clock Divisor High. This value sets the number of cycles SCL will be high. $F_{SCL} = F_{I2Cn\_PCLK} / (CLK\_DIV\_HI + CLK\_DIV\_LO)$ This means that in order to get $F_{SCL} = 100$ kHz set $CLK\_DIV\_HIGH = CLK\_DIV\_LOW = 520$ . ( $F_{I2Cn\_PCLK} = 104$ MHz). The lowest operating frequency is about 50 kHz.	0x2BA

#### 4.6 I2Cn Clock Divider Low register

The I2Cn\_CLK\_LO register holds a terminal count for counting I2Cn\_PCLK cycles to create the low period of the slower I<sup>2</sup>C serial clock, SCL. When reset, the clock divider will be set to run at its reset value frequency.

**Table 510. I2Cn Clock Divider Low (I2C0\_CLK\_LO - 0x1300 A010, I2C1\_CLK\_LO - 0x1300 A410)**

Bit	Symbol	Description	Reset value
31:10	-	Reserved	-
9:0	CLK_DIV_LO	Clock Divisor Low. This value sets the number of I2Cn_PCLK cycles SCL will be low. $FSCL = F_{I2Cn\_PCLK} / (CLK\_DIV\_HI + CLK\_DIV\_LO)$ This means that in order to get $FSCL = 100$ kHz set $CLK\_DIV\_HIGH = CLK\_DIV\_LOW = 520$ . ( $F_{I2Cn\_PCLK} = 104$ MHz). The lowest operating frequency is about 50 kHz.	0x2BA

#### 4.7 I2Cn Slave Address register

The I2Cn\_ADR register holds the I2C bus slave address.

**Table 511. I2Cn Slave Address (I2C0\_ADR - 0x1300 A014, I2C1\_ADR - 0x1300 A414)**

Bit	Symbol	Description	Reset value
31:8	-	Reserved	-
9:0	ADR	ADR is the I2C bus slave address. Bits 6:0 are enabled if the I2C is configured for slave mode. Bits 9:7 are enabled only if it is configured for slave mode and '10-bit addressing'. Note: A soft-reset disables Bits 9:7, see the description of Bits 8 and 9 in the I2Cn_CTRL registers.	0x01A

#### 4.8 I2Cn Receive FIFO level register

The I2Cn\_RXFL is a read only register that contains the number of bytes in the RX FIFO.

**Table 512. I2Cn RX FIFO level (I2C0\_RXFL - 0x1300 A018, I2C1\_RXFL - 0x1300 A018 0x1300 A418)**

Bit	Symbol	Description	Reset value
31:2	-	Reserved	-
1:0	RxFL	Receive FIFO level	0

#### 4.9 I2Cn Transmit FIFO level register

The I2Cn\_TXFL is a read only register that contains the number of bytes in the TX FIFO.

**Table 513. I2Cn TX FIFO level (I2C0\_TXFL - 0x1300 A01C, I2C1\_TXFL - 0x1300 A41C)**

Bit	Symbol	Description	Reset value
31:2	-	Reserved	-
1:0	TxFL	Transmit FIFO level	0

#### 4.10 I2Cn Receive byte count register

The I2Cn\_RXB contains the number of bytes received. The register is reset when I2C transitions from inactive to active.

**Table 514. I2Cn RX byte count (I2C0\_RXB - 0x1300 A020, I2C1\_RXB - 0x1300 A420)**

Bit	Symbol	Description	Reset value
31:16	-	Reserved	-
15:0	RxB	Number of bytes received	N/A

#### 4.11 I2Cn Transmit Byte count register

The I2Cn\_TXB contains the number of bytes transmitted. The register is reset when I2C transitions from inactive to active.

**Table 515. I2Cn TX byte count (I2C0\_TXB - 0x400A 0024, I2C1\_TXB - 0x1300 A424)**

Bit	Symbol	Description	Reset value
31:16	-	Reserved	-
15:0	TxB	Number of bytes sent	N/A

#### 4.12 I2Cn Slave Transmit FIFO register

The I2Cn\_S\_TX FIFO may be cleared via a soft reset, by setting bit 8 in the I2Cn\_CTRL register.

If the controller is configured as a Master/Slave and is operating in a multi-master environment, then only master-transmit data should be written to I2Cn\_TX, slave transmit data should be written to I2Cn\_S\_TX.

If the TX FIFO is written to while full a DATA ABORT exception is generated.

**Table 516. I2Cn Slave TX Data FIFO (I2C0\_S\_TX - 0x1300 A028, I2C1\_S\_TX - 0x1300 A428)**

Bit	Symbol	Description	Reset value
31:8	-	Reserved	-
7:0	TXS	Slave Transmit FIFO data bits 7:0	NA

#### 4.13 I2Cn Slave Transmit FIFO level register

The I2Cn\_S\_TXFL is a read only register that contains the number of bytes in the Slave TX FIFO.

**Table 517. I2Cn Slave TX FIFO level (I2C0\_S\_TXFL - 0x1300 A02C, I2C1\_S\_TXFL - 0x1300 A42C)**

Bit	Symbol	Description	Reset value
31:2	-	Reserved	-
1:0	TxFL	Slave Transmit FIFO level	0

## 5. Functional description

### 5.1 Overview

I2C is a two-wire interface made up of a clock (SCL) and data (SDA). Each of these two wires has a pull-up (or current source). Any device on the bus can pull it to a logic zero or let it float to a logic one (Wire-ANDed). A bus master drives the clock line and is responsible for driving an address on the data wire. A bus slave is any device being

addressed by a master. A bus transmitter writes data to the bus by driving the data line. A bus receiver reads data from the bus. A bus master can be either a transmitter or a receiver; likewise for a bus slave.

### 5.2 I<sup>2</sup>C clock settings

[Table 24–518](#) shows some examples of clock settings for various I2Cn\_PCLK and I<sup>2</sup>C frequencies.

**Table 518. Example I<sup>2</sup>C rate settings**

I2C0/1_PCLK frequency (MHz)	I <sup>2</sup> C clock rate (kHz)	I2Cn_CLK_HI + I2Cn_CLK_LO	I2Cn_CLK_HI	I2Cn_CLK_LO	Comment
104	100	1040	520	520	Symmetric clock (standard for 100 kHz I <sup>2</sup> C)
52	100	520	260	260	Symmetric clock (standard for 100 kHz I <sup>2</sup> C)
12	100	120	60	60	Symmetric clock (standard for 100 kHz I <sup>2</sup> C)
104	400	260	94	166	Asymmetric clock (per 400 kHz I <sup>2</sup> C spec)
52	400	130	47	83	Asymmetric clock (per 400 kHz I <sup>2</sup> C spec)
12	400	30 (rounded up)	12	18	Asymmetric clock (per 400 kHz I <sup>2</sup> C spec). Actual rate will be 393.9 kHz.

### 5.3 I<sup>2</sup>C Data

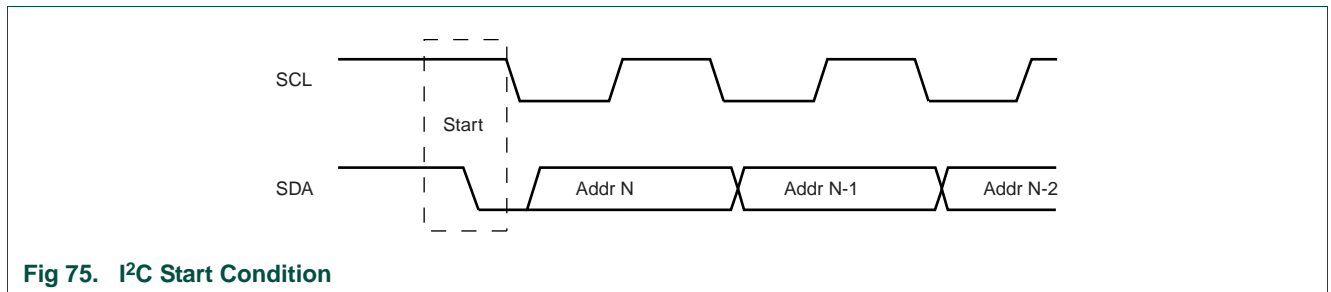

When sending data, the data line, SDA, must change when the clock line, SCL, is low. Data is sampled at the rising edge of SCL. [Figure 24–74](#) shows the relative timing of SDA to SCL

**Fig 74. I<sup>2</sup>C Data**

### 5.4 Start Condition

A start condition is signaled by a high-to-low transition of SDA while SCL is high. [Figure 24–75](#) illustrates a start condition. A bus master can issue a start when the bus is idle or if it already has control of the bus.

**Fig 75. I<sup>2</sup>C Start Condition**

### 5.5 Stop Condition

A stop condition is signaled by a low-to-high transition of SDA while SCL is high. [Figure 24–76](#) illustrates a stop condition.

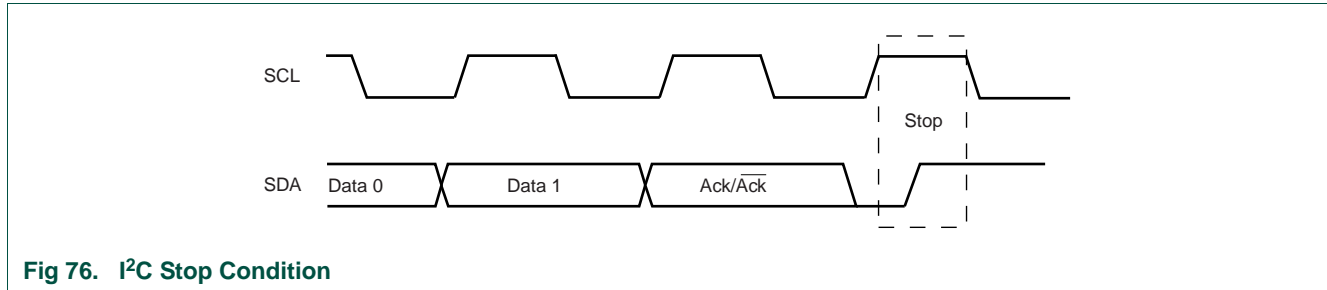

Fig 76. I<sup>2</sup>C Stop Condition

### 5.6 Acknowledge

After every byte is transferred the receiver must acknowledge receipt of the byte through an acknowledge bit. This is done by pulling SDA low for one cycle. The acknowledge is just like a data bit in that SDA must be changed when SCL is low and the acknowledge must be stable for the rising edge of SCL. If a bus master doesn't receive an acknowledge after sending a byte, the master issues a stop condition and the transfer is aborted.

When operating as a master-receiver, the slave-transmitter must release the bus at the end of the transfer so the master can generate a stop condition. To force the slave-transmitter to release, the master receiver does not acknowledge the last byte received. See [Section 24–4.1](#) for additional information.

### 5.7 I<sup>2</sup>C Addresses

I<sup>2</sup>C devices can use 7-bit addressing or 10-bit addressing. The bus master must send out an address after issuing a start condition. The address is sent in MSB to LSB order followed by a read (not write) bit which controls the direction of the following transfer. An example of a 7-bit address is shown in [Figure 24–77](#) where S is a start condition, Ax is bit x of the address, r/w is the read (not write) bit, Ack is the acknowledge, and P is a stop condition.

Fig 77. I<sup>2</sup>C 7-bit device addressing

10-bit addressing is accomplished by sending the address in two bytes. The First byte is 11110xx followed by the r/w bit where xx are the two MSBs of the address. The second byte is the eight LSBs of the address. [Figure 24–78](#) shows 10-bit addressing. Slaves matching the first byte of the address must acknowledge. Slaves matching the second address byte also acknowledge that byte. Writing to a 10-bit address issues the two address bytes followed by the data.

Fig 78. I<sup>2</sup>C 10-bit device addressing

### 5.8 I<sup>2</sup>C Write

To write data on the I<sup>2</sup>C bus using 7-bit addressing, the master sends out a slave address, a write bit, receives an acknowledge, then sends data bytes in MSB to LSB order receiving an acknowledge after each byte, and finally issues a stop. [Figure 24–79](#) illustrates a write operation.

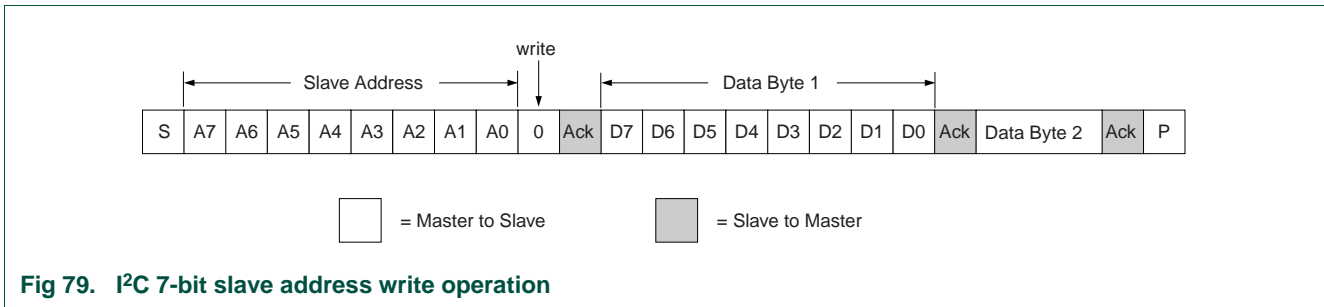

Fig 79. I<sup>2</sup>C 7-bit slave address write operation

To write data on the I<sup>2</sup>C bus using 10-bit addressing, the master sends out the high slave address, a write bit, receives an acknowledge, then sends the low slave address, receives an acknowledge, then sends data bytes in MSB to LSB order receiving an acknowledge after each byte, and finally issues a stop. [Figure 24–80](#) illustrates a 10-bit slave address write operation.

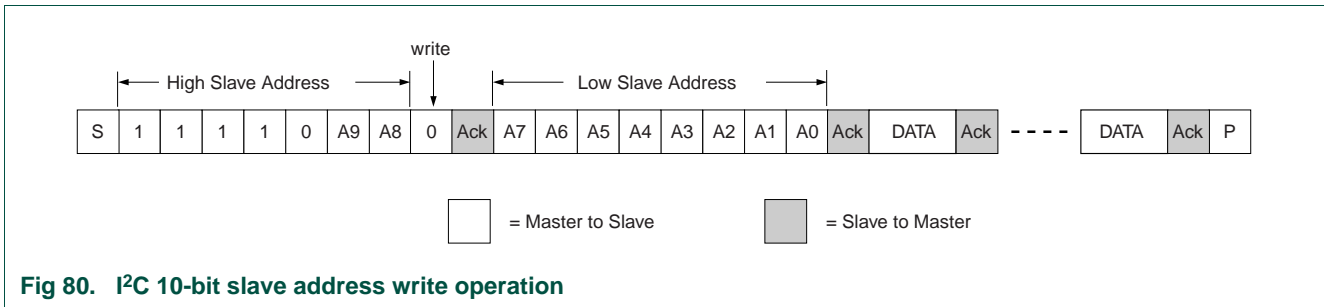

Fig 80. I<sup>2</sup>C 10-bit slave address write operation

### 5.9 I<sup>2</sup>C Read

To read data on the I<sup>2</sup>C bus, the master send out a slave address, a read bit, receives an acknowledge, then receives data bytes in MSB to LSB order sending an acknowledge after each byte, and finally issues a stop. [Figure 24–81](#) illustrates a read operation. The master drives SCL for the entire operation.

Fig 81. I<sup>2</sup>C Read Operation from a 7-bit slave address device

Reading from a 10-bit address is somewhat different; The master must write to the slave before restarting and reading from the same slave. The master must send the first byte with the r/w bit low (write) then second address byte, followed by a restart, then send only the first address byte with the r/w bit high (read), then read bytes from the slave. The last byte read from the slave is not acknowledged to signal the end of the read operation.

Fig 82. I<sup>2</sup>C Reading from a 10-bit slave address device

### 5.10 I<sup>2</sup>C Write/Read

A repeated start condition allows the bus master to reissue an address with the option of changing the r/w bit. The master can issue any number of start conditions before issuing a stop. [Figure 24-83](#) is an example of a write followed by a read where Sr is a repeated start condition.

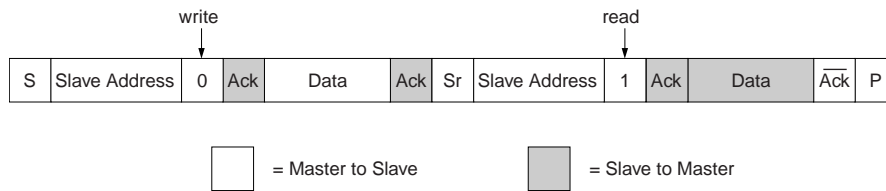

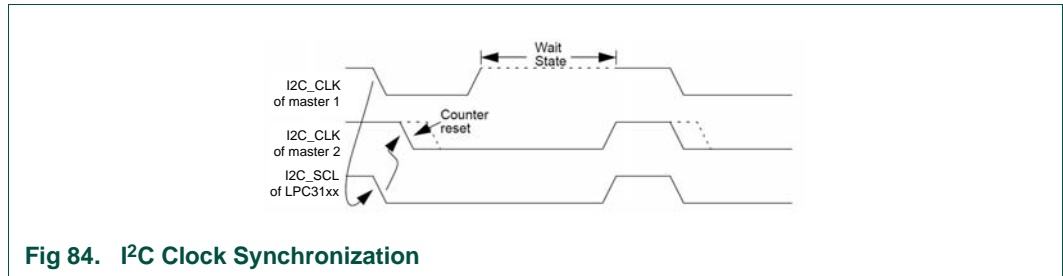

Fig 83. I<sup>2</sup>C 7-bit slave address write then read operation

### 5.11 Bus Arbitration

The I<sup>2</sup>C allows any bus master to start a transfer when the bus is idle. In a multi-master system, it is possible to have more than one master start a transfer at the same time. To arbitrate between masters, all I<sup>2</sup>C masters must monitor the state of the bus while they are driving it. If a master is trying to put a “1” on the bus while another is driving a “0”, the bus will be low (wire-AND) and the master trying to put a “1” on the bus must abort its operation. The master driving a “0” continues its operation unaware that another master aborted a transfer.

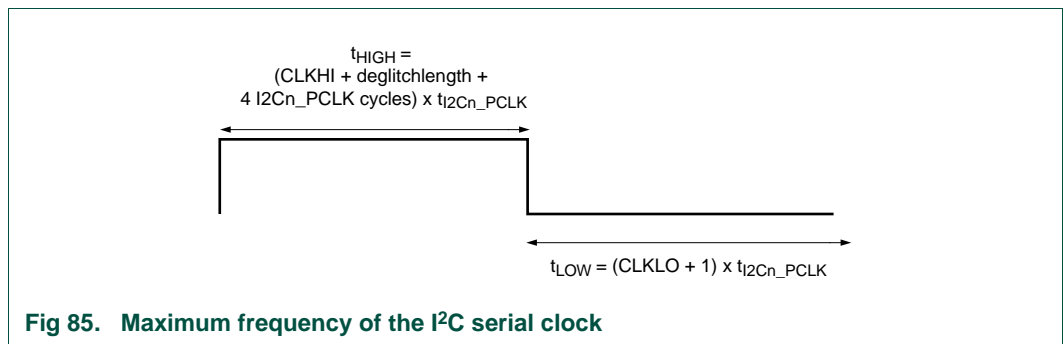

### 5.12 Clock Synchronization

Since different devices can drive SCL at different frequencies, masters must account for this by starting their clock-high timer when SCL actually goes high rather than when it tries to drive it high. Likewise, the master starts counting the clock-low time when SCL actually goes low. An example is shown in [Figure 24–84](#).

**Fig 84. I<sup>2</sup>C Clock Synchronization**

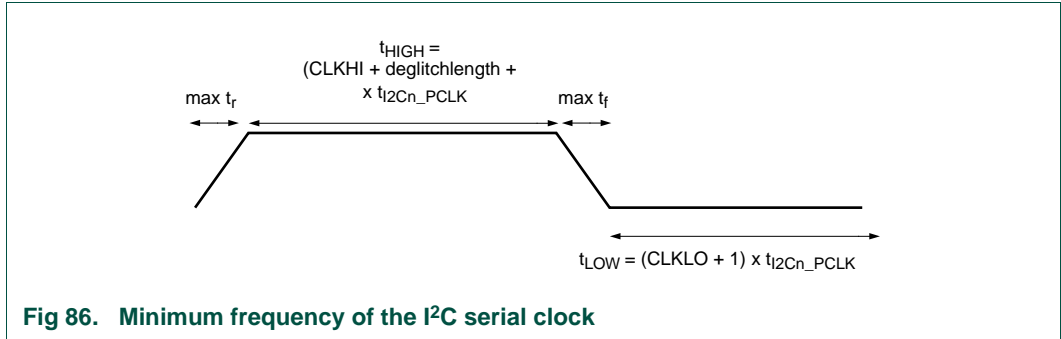

The frequency of the I2C serial clock can be generated with the values of the CLKHI and CLKLO registers. Note that the frequency of the I2C serial clock is dependent of the pull-up resistance  $R_d$  and the load. So this frequency is board dependent and will have a value which is in between the maximal possible frequency and the minimal frequency which is possible for certain values of CLKHI and CLKLO. The de-glitch length is 7 I2Cn\_PCLK cycles in this case. An indication of the maximal frequency of the I2C serial clock can be calculated and determined with the following figure:

**Fig 85. Maximum frequency of the I<sup>2</sup>C serial clock**

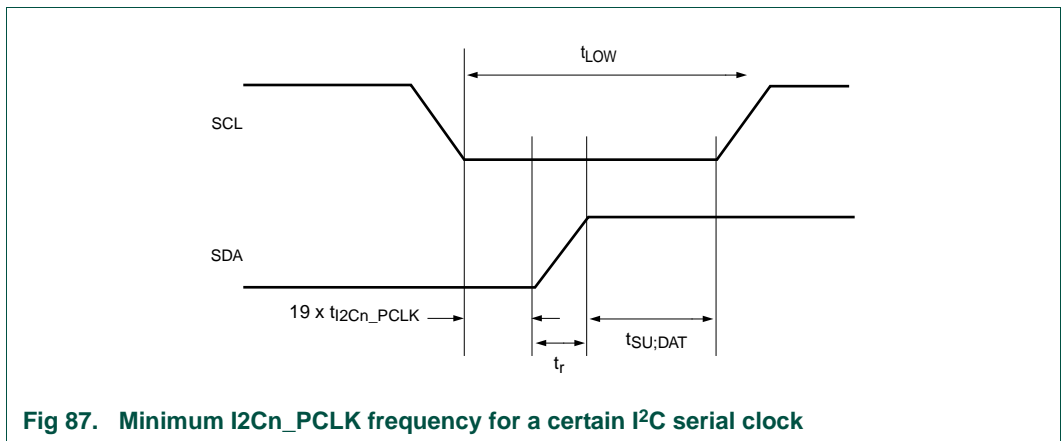

The time for the rising and falling edges are neglected for calculation of the maximum possible frequency. This because the time of the edges are low in comparison with the total period time when  $R_d$  is low and when the load is low. The 4 extra APB cycles added for the high time, results from internal timing and synchronization. The minimum frequency of the I2C serial clock, by certain values of CLKLO and CLKHI can be calculated and determined with the following figure, which shows 1 period of SCL. Maximum and minimum values of  $t_r$ ,  $t_{HIGH}$ ,  $t_f$  and  $t_{LOW}$  are shown in the I2C specification.

**Fig 86. Minimum frequency of the I<sup>2</sup>C serial clock**

The time of the rising edge and falling edge are incorporated in the calculation of the minimal frequency by certain values of CLKHI and CLKLO and with low values of resistance Rd and higher load. This is done because these times are significant in comparison with the total period time. Logic '1' is defined as > 0.7 VDD en the logic '0' is defined as < 0.4 V. The following timing figure shows the constraint of the minimum I2Cn\_PCLK frequency for a certain I2C clock:

**Fig 87. Minimum I2Cn\_PCLK frequency for a certain I<sup>2</sup>C serial clock**

An internal counter of 19 I2Cn\_PCLK cycles is used before SDA may change after the falling edge of SCL. The following formula is used for calculating minimal period time of the I2Cn\_PCLK, by a given value of tLOW of the I2C clock SCL.

$$\left( T_{I2CnPCLK} < \frac{(t_{LOW} - t_r - t_{SU;DAT})}{19} \right)$$

CLKHI and CLKLO can be calculated when  $T_{I2Cn\_PCLK}$  is known:

$$CLKHI = \frac{t_{HIGH}}{T_{I2CnPCLK}} - \text{deglitchlength}$$

$$CLKLO = \frac{t_{LOW}}{T_{I2CnPCLK}} - 1$$

Note that the constraints for  $t_{HIGH}$ ,  $t_{LOW}$ ,  $t_r$  and  $t_{SU;STO}$  can be found in the I2C specification. These values are written down in [Table 24-519](#):

**Table 519. Constraints for  $t_{HIGH}$ ,  $t_{LOW}$ ,  $t_r$  and  $t_{SU;STO}$**

Parameter	Symbol	Standard mode		Fast mode		Unit
		Min	Max	Min	Max	
SCL clock frequency	$f_{SCL}$	0	100	0	400	kHz
LOW period of the SCL clock	$t_{LOW}$	4.7	-	1.3	-	$\mu$ s
HIGH period of the SCL clock	$t_{HIGH}$	4.0	-	0.6	-	$\mu$ s
Rise time of both SDA and SCL signals	$t_r$	-	1000	20 + 0.1Cb	300	ns
Fall time of both SDA and SCL signals	$t_f$	-	300	20 + 0.1Cb	300	ns
Set-up time for STOP condition	$t_{SU;STO}$	4.0	-	0.6	-	$\mu$ s
Data set-up time	$t_{SU;DAT}$	250	-	100	-	ns
I2Cn_PCLK clock frequency (with min. $t_{LOW}$ , max. $t_r$ and min. $t_{SU;DAT}$ ) for reaching max $f_{SCL}$	$f_{I2Cn\_PCLK}$	5.5	-	21.1	-	MHz

## 1. Introduction

The LPC315x contains four fully independent timer modules that can be used to generate interrupts after a pre-set time interval has elapsed.

### 1.1 Features

- Four fully independent timers.  
Each timer has:
  - Individual clock and select input.
  - A 32 bit wide down-counter with selectable pre-scalers (0, 4 or 8 stages of pre-scale) allowing the system clock division by a factor of 1, 16 or 256.
- Support for two modes of operation:
  - Free-running timer: The timer generates an interrupt when the counter reaches zero. The timer wraps around to 0xFFFFFFFF and continues counting down.
  - Periodic timer: The timer generates an interrupt when the counter reaches zero. It reloads the value from a load register and continues counting down from that value. An interrupt will be generated every time the counter reaches zero. This effectively gives a repeated interrupt at a regular interval.
- At any time the current timer value can be read.
- At any time the value in the load register may be re-written, causing the timer to restart.

## 2. General description

### 2.1 Clock signals

The timer speed depends on the system clock PCLK for each timer.

Table 520. Timer module clock signals

Clock Name	I/O	Source/Destination	Description
TIMER0/1/2/3_PCLK	I	CGU	APB clock

**Remark:** The clock is asynchronous to the AHB Clock.

### 2.2 Interface description

#### 2.2.1 Interrupt Requests

The Timer module has four independent interrupt request signals (TIMER0\_INT, TIMER1\_INT, TIMER2\_INT & TIMER3\_INT) to the interrupt controller.

#### 2.2.2 Reset Signals

The CGU provides one asynchronous, active LOW reset signal (PRESETn) to each timer.

### 3. Register overview

**Table 521. Timer module register overview (register base address 0x1300 8000 (Timer0), 0x1300 8400 (Timer1), 0x1300 8800 (Timer2), and 0x1300 8C00 (Timer3))**

Name	R/W	Address offset	Description
TimerLoad	R/W	0x00	Contains the initial 32 bit value of the timer and is also used as the reload value in periodic timer mode.
TimerValue	R	0x04	The value at this location gives the current 32 bit value of the timer.
TimerCtrl	R/W	0x08	Provides enable/disable mode and pre-scale configurations for the timer. This is explained in more detail in the next section.
TimerClear	W	0x0C	Writing to this location clears the interrupt generated by the counter timer.

### 4. Register description

#### 4.1 Timer Load register

**Table 522. Timer Load register (TimerLoad, address 0x1300 8000 (Timer0), 0x1300 8400 (Timer1), 0x1300 8800 (Timer2), and 0x1300 8C00 (Timer3))**

Bit	Symbol	Access	Reset Value	Description
31:0	LOADVALUE	R/W	-	Contains the initial 32 bit value of the timer and is also used as the reload value in periodic timer mode.

#### 4.2 Timer Value register

**Table 523. Timer Value register (TimerValue, address 0x1300 8004 (Timer0), 0x1300 8404 (Timer1), 0x1300 8804 (Timer2), and 0x1300 8C04 (Timer3))**

Bit	Symbol	Access	Reset Value	Description
31:0	VALUE	R	-	Gives the current 32 bit value of the timer.

#### 4.3 Timer Control register

**Table 524. Timer Control register (TimerCtrl, address 0x1300 8008 (Timer0), 0x1300 8408 (Timer1), 0x1300 8808 (Timer2), and 0x1300 8C08 (Timer3))**

Bit	Symbol	R/W	Reset Value	Description
31-8	-	-	-	Undefined. Bits must be written as zero and read as undefined.
7	Enable	R/W	0	0-Timer Disabled 1-Timer Enabled
6	Mode	R/W	0	0-Free running Mode 1-Periodic Timer Mode

**Table 524. Timer Control register (TimerCtrl, address 0x1300 8008 (Timer0), 0x1300 8408 (Timer1), 0x1300 8808 (Timer2), and 0x1300 8C08 (Timer3)) ...continued**

Bit	Symbol	R/W	Reset Value	Description
5-4	-	-	-	Undefined. Bits must be written as zero and read as undefined.
3-2	PreScale	R/W	0	See <a href="#">Table 25–525</a>
1-0	-	-	-	Undefined. Bits must be written as zero and read as undefined.

**Table 525. Pre Scale Bits (Bit 3,2)**

Bit 3	Bit 2	Clock divided by	Stages of Pre-Scale
0	0	1	0
0	1	16	4
1	0	256	8
1	1	Undefined	n/a

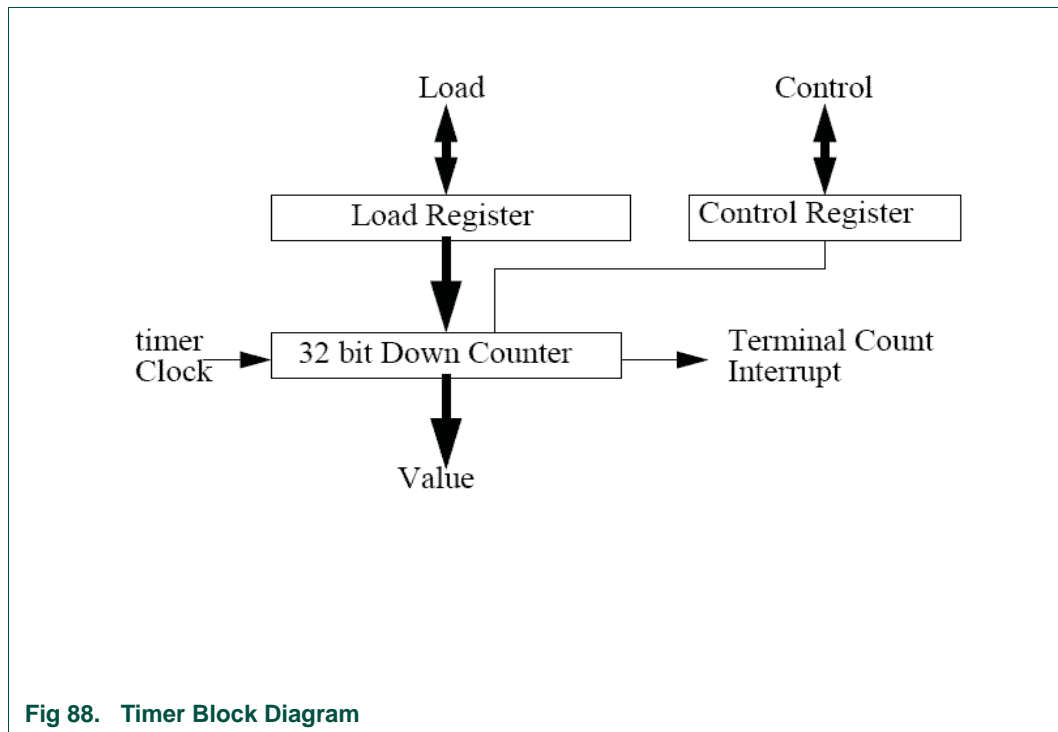

#### 4.4 Timer Clear register

**Table 526. Timer Clear register (TimerClear, address 0x1300 800C (Timer0), 0x1300 840C (Timer1), 0x1300 880C (Timer2), and 0x1300 8C0C (Timer3))**

Bit	Symbol	Access	Reset Value	Description
31:0	CLEAR	W	-	Writing to this location clears the interrupt generated by the counter timer.

## 5. Functional description

The timer is loaded by writing to the Load register and then, if enabled, the timer will count down to zero. On reaching a count of zero an interrupt will be generated. The interrupt may be cleared by writing to the Clear register.

**Fig 88. Timer Block Diagram**

After reaching a zero count, if the timer is operating in free-running mode then the timer will continue to decrement from its maximum value. If periodic timer mode is selected then the timer will reload from the Load register and continue to decrement. In this mode the timer will effectively generate a periodic interrupt. The mode is selected by a bit in the Control register.

For example, in periodic mode if timer requires to generate an interrupt every 1ms and clock frequency is 1MHz then value 0x3E8 need to be programmed in the Load Register. As counter counts down every clock cycle it will reach 0 after 1ms.

At any point the current timer value may be read from the Value register.

At any point the timer\_load may be re-written. This will cause the timer to restart to the timer\_load value.

The timer is enabled by a bit in the control register. At reset the timer will be disabled, the interrupt will be cleared and the Load Register will be undefined. The mode and pre-scale value will also be undefined.

The timer clock is generated by a pre-scale unit. The timer clock may be the system clock, the system clock divided by 16, which is generated by 4 bits of pre-scale, or the system clock divided by 256, which is generated by a total of 8 bits of pre-scale.

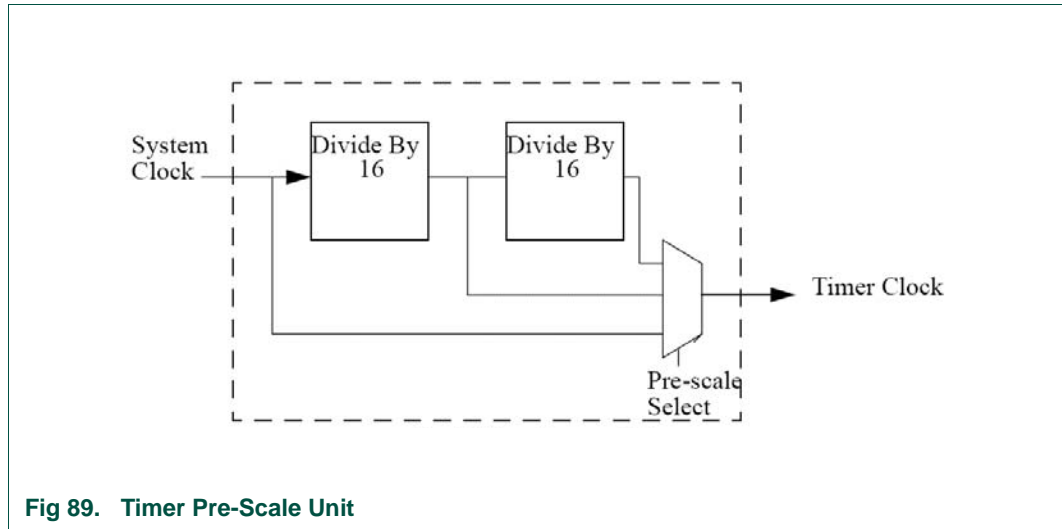

Fig 89. Timer Pre-Scale Unit

## 6. Power optimization

Power saving can be achieved by switching off the clock to this module by clock gating when the module is not in use. Clock gating can be enabled by setting the RUN bit in PCR register for a particular clock in CGU.

## 7. Programming guide

To set-up a normal operation following registers has to be programmed:

- Register TimerLoad should be written with the count value. Note that when a new value is written to the load register, the timer will start.
- Register TimerControl should be programmed.

## 1. Introduction

This pulse width modulation module (PWM) can be used to convert a digital signal to an analogue value by simple external low-pass filtering. The duration of the PWM output being at a high level is programmed by software. This module also supports pulse density modulation (PDM). A PDM signal is a stream of constant-width pulses, having a density (rate of occurrence) proportional to a corresponding digital value. The PWM is intended to be used for backlighting.

### 1.1 Features

This module has the following features:

- Programmable Pulse Width Modulation (PWM).
- Supports Pulse Density Modulation (PDM).
- Output can be set to fixed high.
- Output frequency can be adjusted.
- Loop mode.

## 2. General description

In the PWM mode, a free running 12-bit counter is compared against a value programmed in PWM\_TMR[11:0]. The PWM output is high if the value of the counter is lower than the value programmed in a register, and low otherwise. (see [Figure 26–90 “PWM output”](#)) Additional features like PDM and LOOP-mode are also supported.

## 2.1 Interface description

### 2.1.1 Clock signals

Table 527. Clock Signals of the PWM Module

Clock name	Acronym	I/O	Source /Destination	Description
PWM_PCLK	pclk	I	CGU	APB bus clock. This is the normal APB bus clock.
PWM_PCLK_REGS	pclk_regs	I	CGU	APB bus clock. Gated APB clock, used for register access.
PWM_CLK	pwm_clk	I	CGU	PWM output clock. Clock used for generating the output of the PWM. Adjustable and derived from the same clock base, as the other clocks.

### 2.1.2 Pin connections

Table 528. Pin connections of the PWM block

Name	I/O	Description
PWM_DATA	O	PWM modulated output signal to be used for backlighting. The value of PWM_DATA is tri-stated during reset until the desired function is programmed.

### 2.1.3 Reset signals

The CGU provides two reset signals to the PWM: An APB reset signal (PNRES) and the PWM functional reset, an active low asynchronous reset signal (PWM\_RES\_AN).

## 3. Register overview

Table 529. PWM register overview (register base address 0x1300 9000)

Name	R/W	Address Offset	Description
tmr	R/W	0x000	Timer Register
cntl	R/W	0x004	Control Register

## 4. Register description

PWM contains registers (R/W access is handled through APB bus):

- tmr register only includes a timer value, used for pulse width or pulse density.
- cntl register is divided into 4 fields: cntl.clk, cntl.hi, cntl.loop and cntl.pdm.

Table 530. Timer register (tmr, address 0x1300 9000)

Bit	Symbol	R/W	Reset Value	Description
11.0	MR	R/W	NA	Timer used for PWM and PDM

Table 531. Control register (cntl, address 0x1300 9004)

Bit	Symbol	R/W	Reset Value	Description
1:0	CLK	R/W	0	This will define how the pwm_clk is used for generating the output pulses: 00 = pwm_clk 01 = pwm_clk/2 10 = pwm_clk/4 11 = pwm_clk/8
4	HI	R/W	0	If HI, is set to '1', the pwm output will be forced high.
6	LOOP	R/W	0	If loop is set to '1', the output is inverted with a repetition of the top4 tmr bits
7	PDM	R/W	0	PDM set to '1' will select PDM mode (PWM is standard: PDM = '0')

## 5. Functional description

In PWM mode, a free running 12-bit counter is compared against a value programmed in PMR\_TMR [11:0]. The PWM output is high if the value of the counter is lower than the value programmed in a register and low otherwise. (see [Figure 26–90 “PWM output”](#))

In PDM mode, the programmed value TMR [11:0] determines the number of clock cycles to be counted before a PWM pulse is delivered. The total number of pulses that will be generated is defined by the TMR value.

In both modes, the LOOP bit of the Control Register can be used to allow switching the output level after a programmed number (M) of output pulses. This number M is defined by the top 4 bits of the tmr register.

The PWM output clock is derived from the PWM\_CLK, and it is selected through the cntl register. Supported values are PWM\_CLK, PWM\_CLK/2, PWM\_CLK/4 and PWM\_CLK/8. This is internally not a direct clock divider but is only used for the output frequency.

## 6. Programming guide

The PWM is initialized with a tri-stated output. The output will be enabled automatically after setting the TMR value. Depending on the implementation of the backlighting implementation one can choose to initialize the output high by selection the HI mode for an active-low backlight or, when the backlight is active-high, the PWM can be initialized by setting the TMR value to '0'.

For driving the LCD backlight, only the PWM and HI modes will be necessary. The internal timer will count up to 4095 (12-bit). The PWM output will have the frequency of the (PWM\_CLK frequency) / 4095, with a duty-cycle of ((PWM\_TMR) / 4095) x 100%.

## 1. Introduction

---

The System Control Registers (SysCReg) module provides a register interface for some of the high-level settings in the system such as multiplexers and mode settings.

### 1.1 Features

- The SysCReg module contains registers for generic LPC315x configuration:
  - PAD multiplexing and configuration settings
  - USB PLL settings
  - SDRAM refresh configuration
  - ISROM and ISRAM configuration
  - MPMC configuration
  - ADC configuration
  - RNG configuration
  - SD/MMC configuration
  - AHB priority configuration
  - Shadow memory configuration
  - EBI configuration
- The module only consumes power when data is written to it.

## 2. Interface description

---

### 2.1 Clock signals

Table 532. Clock Signals of the SysCReg Module

Clock Name	I/O	Source/Destination	Description
SYSCREG_PCLK	I	CGU	Main Clock of the module; The logic in this module runs on this clock.

### 2.2 Reset signals

The system control block is reset by an APB reset.

### 3. Register overview

Table 533. Register overview: SysCReg block (register base address 0x1300 2800)

Name	R/W	Address offset	Description
-	R/W	0x000 to 0x004	Reserved
<b>Miscellaneous system configuration registers, part1</b>			
SYSCREG_EBI_MPMC_PRIO	R/W	0x008	Priority of MPMC channel for EBI interface
SYSCREG_EBI_NANDC_PRIO	R/W	0x00C	Priority of NAND controller channel for EBI interface
SYSCREG_EBI_UNUSED_PRIO	R/W	0x010	Priority of unused channel
SYSCREG_RING_OSC_CFG	R/W	0x014	RING oscillator configuration register
SYSCREG_ADC_PD_ADC10BITS	R/W	0x018	Powerdown register of ADC 10bits
SYSCREG_CGU_DYN_HP0	R/W	0x01C	reserved
SYSCREG_CGU_DYN_HP1	R/W	0x020	reserved
SYSCREG_ABC_CFG	R/W	0x024	AHB burst control register
SYSCREG_SD_MMC_CFG	R/W	0x028	SD_MMC (MCI) configuration register
SYSCREG_MCI_DELAYMODES	R/W	0x02C	Delay register for the SD_MMC (MCI) clocks
<b>USB configuration registers</b>			
SYSCREG_USB_ATX_PLL_PD_REG	R/W	0x030	Power down register of USB ATX PLL

SYSCREG_MI2STX_CLK0_PCTRL	R/W	0x0E0	Provides the input to the programmable section of the pad, MI2STX_CLK0
SYSCREG_MI2STX_BCK0_PCTRL	R/W	0x0E4	Provides the input to the programmable section of the pad, MI2STX_BCK0

Table 533. Register overview: SysCReg block (register base address 0x1300 2800) ...continued

Name	R/W	Address offset	Description
SYSCREG_EBI_A_1_CLE_PCTRL	R/W	0x0E8	Provides the input to the programmable section of the pad, EBI_A_1_CLE
SYSCREG_EBI_NCAS_BLOUT_0_PCTRL	R/W	0x0EC	Provides the input to the programmable section of the pad, EBI_NCAS_BLOUT_0
SYSCREG_NAND_NCS_3_PCTRL	R/W	0x0F0	Provides the input to the programmable section of the pad, NAND_NCS_3
SYSCREG_MLCD_DB_0_PCTRL	R/W	0x0F4	Provides the input to the programmable section of the pad, MLCD_DB_0
SYSCREG_EBI_DQM_0_NOE_PCTRL	R/W	0x0F8	Provides the input to the programmable section of the pad, EBI_DQM_0_NOE
SYSCREG_EBI_D_0_PCTRL	R/W	0x0FC	Provides the input to the programmable section of the pad, EBI_D_0
SYSCREG_EBI_D_1_PCTRL	R/W	0x100	Provides the input to the programmable section of the pad, EBI_D_1
SYSCREG_EBI_D_2_PCTRL	R/W	0x104	Provides the input to the programmable section of the pad, EBI_D_2
SYSCREG_EBI_D_3_PCTRL	R/W	0x108	Provides the input to the programmable section of the pad, EBI_D_3
SYSCREG_EBI_D_5_PCTRL	R/W	0x10C	Provides the input to the programmable section of the pad, EBI_D_5
SYSCREG_EBI_D_6_PCTRL	R/W	0x110	Provides the input to the programmable section of the pad, EBI_D_6
SYSCREG_EBI_D_7_PCTRL	R/W	0x114	Provides the input to the programmable section of the pad, EBI_D_7
SYSCREG_EBI_D_8_PCTRL	R/W	0x118	Provides the input to the programmable section of the pad, EBI_D_8
SYSCREG_EBI_D_15_PCTRL	R/W	0x11C	Provides the input to the programmable section of the pad, EBI_D_15
SYSCREG_I2STX_DATA1_PCTRL	R/W	0x120	Provides the input to the programmable section of the pad, I2STX_DATA1
SYSCREG_I2STX_BCK1_PCTRL	R/W	0x124	Provides the input to the programmable section of the pad, I2STX_BCK1
SYSCREG_I2STX_WS1_PCTRL	R/W	0x128	Provides the input to the programmable section of the pad, I2STX_WS1
SYSCREG_I2SRX_DATA0_PCTRL	R/W	0x12C	Provides the input to the programmable section of the pad, I2SRX_DATA0
SYSCREG_I2SRX_WS0_PCTRL	R/W	0x130	Provides the input to the programmable section of the pad, I2SRX_WS0
SYSCREG_I2SRX_DATA1_PCTRL	R/W	0x134	Provides the input to the programmable section of the pad, I2SRX_DATA1
SYSCREG_I2SRX_BCK1_PCTRL	R/W	0x138	Provides the input to the programmable section of the pad, I2SRX_BCK1
SYSCREG_I2SRX_WS1_PCTRL	R/W	0x13C	Provides the input to the programmable section of the pad, I2SRX_WS1
SYSCREG_SYSCLK_O_PCTRL	R/W	0x140	Provides the input to the programmable section of the pad, SYSCLK_O

Table 533. Register overview: SysCReg block (register base address 0x1300 2800) ...continued

Name	R/W	Address offset	Description
SYSCREG_PWM_DATA_PCTRL	R/W	0x144	Provides the input to the programmable section of the pad, PWM_DATA
SYSCREG_UART_RXD_PCTRL	R/W	0x148	Provides the input to the programmable section of the pad, UART_RXD
SYSCREG_UART_TXD_PCTRL	R/W	0x14C	Provides the input to the programmable section of the pad, UART_TXD
SYSCREG_I2C_SDA1_PCTRL	R/W	0x150	Provides the input to the programmable section of the pad, I2C_SDA1
SYSCREG_I2C_SCL1_PCTRL	R/W	0x154	Provides the input to the programmable section of the pad, I2C_SCL1
SYSCREG_CLK_256FS_O_PCTRL	R/W	0x158	Provides the input to the programmable section of the pad, CLK_256FS_O
SYSCREG_GPIO0_PCTRL	R/W	0x15C	Provides the input to the programmable section of the pad, GPIO0
SYSCREG_GPIO2_PCTRL	R/W	0x160	Provides the input to the programmable section of the pad, GPIO2
SYSCREG_GPIO3_PCTRL	R/W	0x164	Provides the input to the programmable section of the pad, GPIO3
SYSCREG_GPIO4_PCTRL	R/W	0x168	Provides the input to the programmable section of the pad, GPIO4
SYSCREG_GPIO11_PCTRL	R/W	0x16C	Provides the input to the programmable section of the pad, GPIO11
SYSCREG_GPIO12_PCTRL	R/W	0x170	Provides the input to the programmable section of the pad, GPIO12
SYSCREG_GPIO13_PCTRL	R/W	0x174	Provides the input to the programmable section of the pad, GPIO13
SYSCREG_GPIO14_PCTRL	R/W	0x178	Provides the input to the programmable section of the pad, GPIO14
SYSCREG_GPIO15_PCTRL	R/W	0x17C	Provides the input to the programmable section of the pad, GPIO15
SYSCREG_GPIO16_PCTRL	R/W	0x180	Provides the input to the programmable section of the pad, GPIO16
SYSCREG_GPIO17_PCTRL	R/W	0x184	Provides the input to the programmable section of the pad, GPIO17
SYSCREG_GPIO18_PCTRL	R/W	0x188	Provides the input to the programmable section of the pad, GPIO18
SYSCREG_GPIO19_PCTRL	R/W	0x18C	Provides the input to the programmable section of the pad, GPIO19
SYSCREG_GPIO20_PCTRL	R/W	0x190	Provides the input to the programmable section of the pad, GPIO20
SYSCREG_SPI_MISO_PCTRL	R/W	0x194	Provides the input to the programmable section of the pad, SPI_MISO
SYSCREG_SPI_MOSI_PCTRL	R/W	0x198	Provides the input to the programmable section of the pad, SPI_MOSI
SYSCREG_SPI_CS_IN_PCTRL	R/W	0x19C	Provides the input to the programmable section of the pad, SPI_CS_IN

Table 533. Register overview: SysCReg block (register base address 0x1300 2800) ...continued

Name	R/W	Address offset	Description
SYSCREG_SPI_SCK_PCTRL	R/W	0x1A0	Provides the input to the programmable section of the pad, SPI_SCK
SYSCREG_SPI_CS_OUT0_PCTRL	R/W	0x1A4	Provides the input to the programmable section of the pad, SPI_CS_OUT0
SYSCREG_NAND_NCS_0_PCTRL	R/W	0x1A8	Provides the input to the programmable section of the pad, NAND_NCS_0
SYSCREG_NAND_NCS_1_PCTRL	R/W	0x1AC	Provides the input to the programmable section of the pad, NAND_NCS_1
SYSCREG_NAND_NCS_2_PCTRL	R/W	0x1B0	Provides the input to the programmable section of the pad, NAND_NCS_2
SYSCREG_MLCD_CSB_PCTRL	R/W	0x1B4	Provides the input to the programmable section of the pad, MLCD_CSB
SYSCREG_MLCD_DB_1_PCTRL	R/W	0x1B8	Provides the input to the programmable section of the pad, MLCD_DB_1
SYSCREG_MLCD_E_RD_PCTRL	R/W	0x1BC	Provides the input to the programmable section of the pad, MLCD_E_RD
SYSCREG_MLCD_RS_PCTRL	R/W	0x1C0	Provides the input to the programmable section of the pad, MLCD_RS
SYSCREG_MLCD_RW_WR_PCTRL	R/W	0x1C4	Provides the input to the programmable section of the pad, MLCD_RW_WR
SYSCREG_MLCD_DB_3_PCTRL	R/W	0x1C8	Provides the input to the programmable section of the pad, MLCD_DB_3
SYSCREG_MLCD_DB_5_PCTRL	R/W	0x1CC	Provides the input to the programmable section of the pad, MLCD_DB_5
SYSCREG_MLCD_DB_6_PCTRL	R/W	0x1D0	Provides the input to the programmable section of the pad, MLCD_DB_6
SYSCREG_MLCD_DB_8_PCTRL	R/W	0x1D4	Provides the input to the programmable section of the pad, MLCD_DB_8
SYSCREG_MLCD_DB_9_PCTRL	R/W	0x1D8	Provides the input to the programmable section of the pad, MLCD_DB_9
SYSCREG_MLCD_DB_10_PCTRL	R/W	0x1DC	Provides the input to the programmable section of the pad, MLCD_DB_10
SYSCREG_MLCD_DB_11_PCTRL	R/W	0x1E0	Provides the input to the programmable section of the pad, MLCD_DB_11
SYSCREG_MLCD_DB_12_PCTRL	R/W	0x1E4	Provides the input to the programmable section of the pad, MLCD_DB_12
SYSCREG_MLCD_DB_13_PCTRL	R/W	0x1E8	Provides the input to the programmable section of the pad, MLCD_DB_13
SYSCREG_MLCD_DB_14_PCTRL	R/W	0x1EC	Provides the input to the programmable section of the pad, MLCD_DB_14
SYSCREG_MLCD_DB_15_PCTRL	R/W	0x1F0	Provides the input to the programmable section of the pad, MLCD_DB_15
SYSCREG_MGPIO5_PCTRL	R/W	0x1F4	Provides the input to the programmable section of the pad, MGPIO5
SYSCREG_MGPIO7_PCTRL	R/W	0x1F8	Provides the input to the programmable section of the pad, MGPIO5

Table 533. Register overview: SysCReg block (register base address 0x1300 2800) ...continued

Name	R/W	Address offset	Description
SYSCREG_MGPI08_PCTRL	R/W	0x1FC	Provides the input to the programmable section of the pad, MGPI08
SYSCREG_MGPI010_PCTRL	R/W	0x200	Provides the input to the programmable section of the pad, MGPI010
SYSCREG_MNAND_RYBN1_PCTRL	R/W	0x204	Provides the input to the programmable section of the pad, MNAND_RYBN1
SYSCREG_MNAND_RYBN2_PCTRL	R/W	0x208	Provides the input to the programmable section of the pad, MNAND_RYBN2
SYSCREG_MNAND_RYBN3_PCTRL	R/W	0x20C	Provides the input to the programmable section of the pad, MNAND_RYBN3
SYSCREG_MUART_CTS_N_PCTRL	R/W	0x210	Provides the input to the programmable section of the pad, MUART_CTS_N
SYSCREG_MI2STX_DATA0_PCTRL	R/W	0x218	This register, SYSCREG_MI2STX_DATA0_PCTRL, provides the input to the programmable section of the pad, MI2STX_DATA0
SYSCREG_MI2STX_WS0_PCTRL	R/W	0x21C	Provides the input to the programmable section of the pad, MI2STX_WS0
SYSCREG_EBI_NRAS_BLOUT_1_PCTRL	R/W	0x220	Provides the input to the programmable section of the pad, EBI_NRAS_BLOUT_1
SYSCREG_EBI_A_0_ALE_PCTRL	R/W	0x224	Provides the input to the programmable section of the pad, EBI_A_0_ALE
SYSCREG_EBI_NWE_PCTRL	R/W	0x228	Provides the input to the programmable section of the pad, EBI_NWE
SYSCREG_ESHCTRL_SUP4	R/W	0x22C	Provides the input to control the performance of the pad at 1.8 and 3.3 V (Nandflash/EBI pads)
SYSCREG_ESHCTRL_SUP8	R/W	0x230	Provides the input to control the performance of the pad at 1.8 and 3.3 V (LCD interface/SDRAM pads)

## 4. Register description

### 4.1 Miscellaneous system control registers, part 1

#### 4.1.1 EBI timeout registers

Table 534. SYSCREG\_EBI\_MPMC\_PRIO (address 0x1300 2808)

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9:0	TIMEOUTVALUE	R/W	0x0	Time out value of the MPMC channel. The higher the time out value the lower the priority is.

Table 535. SYSCREG\_EBI\_NANDC\_PRIOR (address 0x1300 280C)

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9:0	TIMEOUTVALUE	R/W	0xF	Time out value of the NAND controller channel. The higher the time out value the lower the priority is.

Table 536. SYSCREG\_EBI\_UNUSED\_PRIOR (address 0x1300 2810)

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9:0	TIMEOUTVALUE	R/W	0xF	Time out value of unused channel. Program 0x3F to set this channel as lowest priority.

#### 4.1.2 Ring oscillator enable register

Table 537. RING\_OSC\_CFG (address 0x1300 2814)

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1	ring_osc_cfg_osc1_en	R/W	0x1	Enable of the ring oscillator 1
0	ring_osc_cfg_osc0_en	R/W	0x1	Enable of the ring oscillator 0

#### 4.1.3 ADC power-down register

Table 538. SYSCREG\_ADC\_PD\_ADC10BITS (address 0x1300 2818)

Bit	Variable	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	adc_pd_adc10bits	R/W	0x0	Powerdown bit 10 bits ADC. '0' activates the 10 bit ADC. See also <a href="#">Section 16-6</a> .

#### 4.1.4 AHB master configuration register

Table 539. SYSCREG\_ABC\_CFG (address 0x1300 2824)

Bit	AHB MASTER	R/W	Reset Value	Description
31:12	Reserved	R/W	0x0	Reserved
11:9	Usb_otg	R/W	0x0	3 bits for the AHB master USB_OTG to control its AHB bus bandwidth
8:6	arm926ejs_i	R/W	0x0	3 bits for the AHB master ARM926EJS instruction port to control its AHB bus bandwidth
5:3	arm926ejs_d	R/W	0x0	3 bits for the AHB master ARM926EJS data port to control its AHB bus bandwidth
2:0	Simple dma	R/W	0x0	3 bits for the AHB master dma to control its AHB bus bandwidth

For each AHB master, the 3 control bits correspond to the register bits as listed in [Table 27–540](#).

**Table 540. AHB master control bits**

Bit	MODE	Description
000	Normal mode	The default setting. This setting does not impact normal operation.No manipulations will be performed on the AHB signals
001	Make any burst a non-sequential access	When the selected master performs a burst operation, it will be treated like single transfers.This allows the AHB multilayer to re-arbitrate after each single access.Note: It will make the data-transfers very inefficient on the AHB bus, slowing down the selected master more than the other modes.
010	SPlit to 4-beat	This setting will break an INCR8 or INCR16 burst to a 4-burst INCR. If the selected master puts an 8-beat or 16-beat incrementing burst on the bus, it will be split after every 4 words, allowing the AHB multilayer to re-arbitrate. This setting improves the access speed of the other masters.
011	SPlit to 8-beat	This setting will break any INCR burst to a 8-burst INCR. If the selected master puts a 16-beat incrementing burst on the bus, it will be split at the 8-th word, allowing the AHB multilayer to re-arbitrate in the middle.This setting improves the access speed of the other masters (goal: YUV).
100	eXTend to 8-beat	This setting will extend two sequential 4-beat incr to an '8-beat'. This only works if the master really has 2 sequential words on the bus, without delays. The hardware checks if the second word is sequential to the first word and will extend the transfer to 8 words.This will give the selected master more bandwidth compared to other masters if bus-arbitration is required.
101	eXTend to 16-beat	This setting will extend two sequential 8-beat incr to a '16-beat'. This only works if the master really has 2 sequential words on the bus, without delays. The hardware checks if the second word is sequential to the first word and will extend the transfer to 16 words.This will give the selected master more bandwidth compared to other masters if bus-arbitration is required.
110	SPlit to 4-beat	This setting will break an WRAP8 to WRAP4. This will break a wrapping 8-beat burst to two 4-beat wrapping words.This will only be done if the transfer is aligned with the beginning of an 8-beat burst.
111	eXTend to 32-beat	This setting will extend four sequential 8-beat incr (or multi 4-beats or 16-beats) to a '32-beat'. This only works if the master really sets 2 sequential words on the bus, without delays. The hardware checks if the second word is sequential to the first word and will extend the transfer to 32 words.This will give the selected master more bandwidth compared to other masters if bus-arbitration is required.

## 4.2 SD/MMC configuration registers

Table 541. SYSCREG\_SD\_MMC\_CFG (address 0x1300 2828)

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	0x0	reserved
1	card_detect_n	R/W	0x1	Card detect signal. 0: card is present. Default is 1. Any change in this signal will cause card_detect interrupt in SD_MMC module, if enabled. Software should program this bit by detecting the event from unused external GPIO pin, so that the SD_MMC module responds to the event.
0	card_write_prt	R/W	0x0	Card write protect signal for SD cards. 1: write is protected. Default is zero. Software should program this bit by detecting the event from unused external GPIO pin, so that the SD_MMC module responds to the event.

Table 542. SYSCREG\_MCI\_DELAYMODES (address 0x1300 282C)

Bit	Symbol	R/W	Reset Value	Description
31:5	-	-	0x0	reserved
4	delay_enable	R/W	0x0	Enable delay cells.
3:0	delay_cells	R/W	0x0	This bus-signal specifies the number of delay cells to obtain the needed delay for cclk_in_drv. The delay should be ~5ns in comparison to cclk_out for SD cards, 2 ns for high-speed SD cards and 3 ns for (H)MMC and CE-ATA. (Cards need x ns holds on all inputs, so all outputs clocked out of cclk_in are re-clocked by cclk_in_drv to meet card hold-time requirement.). See SD_MMC chapter for more details.

## 4.3 USB registers

Table 543. USB\_ATX\_PLL\_PD\_REG (address 0x1300 2830)

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	USB_ATX_PLL_PD_REG	R/W	0x1	Powerdown bit of the USB pll. 0: in powerdown mode 1: in active mode

Table 544. USB\_OTG\_CFG (address 0x1300 2834)

Bit	Symbol	R/W	Reset Value	Description
31:5	-	-	-	Reserved
4	Reserved	R/W	0x0	-
3	usb_otg_vbus_pwr_fault	R/W	0x0	Indication of the charge pump over-current. Software should set this bit when it detects external wake-up event (from external GPIO pin) in host mode so that USB_OTG responds to the event. For more explanation see <a href="#">Table 8–125</a> .
2	usb_otg_dev_wakeup_n	R/W	0x0	External wakeup signal for device mode. Software should set this bit when it detects external wake-up event (from external GPIO pin) in host mode so that USB_OTG block responds to the event. For more explanation see <a href="#">Section 8–9.2</a> .
1	usb_otg_host_wakeup_n	R/W	0x1	External wake-up signal for host mode. Software should set this bit when it detects external wake-up event (from external GPIO pin) in host mode so that USB_OTG block responds to the event. For more explanation see <a href="#">Section 8–9.3</a> .
0	-	R/W	0x0	Reserved

Table 545. USB\_OTG\_PORT\_IND\_CTL (address 0x1300 2838)

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1:0	USB_OTG_PORT_IND_CTL	R	0x0	Status bits for USB connector LEDs: 00=off 01=amber 10=green 11=undefined See <a href="#">Section 8–4.2.14</a> . Software should read this register and drive USB LEDs (if present on board) appropriately.

### 4.3.1 USB PLL configuration registers

Table 546. USB\_PLL\_NDEC (address 0x1300 2840)

Bit	Symbol	R/W	Reset Value	Description
31:10	-	-	-	Reserved
9:0	USB_PLL_NDEC	R/W	0x0	Pre-divider for the USB pll. The default value should not be modified.

**Table 547. USB\_PLL\_MDEC (address 0x1300 2844)**

Bit	Symbol	R/W	Reset Value	Description
31:17	-	-	-	Reserved
16:0	USB_PLL_MDEC	R/W	0x7FFA	Feedback-divider for the USB pll. The default value should not be modified.

**Table 548. USB\_PLL\_PDEC (address 0x1300 2848)**

Bit	Symbol	R/W	Reset Value	Description
31:4	-	-	-	Reserved
3:0	USB_PLL_PDEC	R/W	0x0	Feedback-divider for the USB pll. The default value should not be modified.

**Table 549. USB\_PLL\_SELR (address 0x1300 284C)**

Bit	Symbol	R/W	Reset Value	Description
31:4	-	-	-	Reserved
3:0	USB_PLL_SELR	R/W	0x0	Bandwidth selection selr. This should not be modified.

**Table 550. USB\_PLL\_SELI (address 0x1300 2850)**

Bit	Symbol	R/W	Reset Value	Description
31:4	-	-	-	Reserved
3:0	USB_PLL_SELI	R/W	0x18	Bandwidth selection seli. This should not be modified.

**Table 551. USB\_PLL\_SELP (address 0x1300 2854)**

Bit	Symbol	R/W	Reset Value	Description
31:4	-	-	-	Reserved
3:0	USB_PLL_SELP	R/W	0xB	Bandwidth selection selp. This should not be modified.

#### 4.4 ISRAM configuration registers

These registers contain the waitstates programming for the internal Ram (ISRAM0/1).

**Table 552. SYSCREG\_ISRAM0\_LATENCY\_CFG (address 0x1300 2858)**

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1:0	Isram0_latency_cfg	R/W	0x0	Number of waitstates. 00=0 waitstates 01=1 waitstate 11=2 waitstates

Table 553. SYSCREG\_ISRAM1\_LATENCY\_CFG (address 0x1300 285C)

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1:0	Isram1_latency_cfg	R/W	0x0	Number of waitstates. 00=0 waitstates 01=1 waitstate 11=2 waitstates

## 4.5 ISROM configuration registers

This register contains the waitstates programming for the internal Ram (ISRROM).

Table 554. SYSCREG\_ISROM\_LATENCY\_CFG (address 0x1300 2860)

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1:0	Isrom_latency_cfg	R/W	0x0	Number of waitstates. 00=0 waitstates 01=1 waitstate 11=2 waitstates

## 4.6 MPMC configuration registers

### 4.6.1 Static memory chip and address select modes

Table 555. SYSCREG\_AHB\_MPMC\_MISC (address 0x1300 2864)

Bit	Symbol	R/W	Reset Value	Description
31:9	-	-	-	Reserved
8	ahb_mpmc_misc_rel1config	R/W	0x0	Static memory address mode select (more information see below).
7	ahb_mpmc_misc_stcs1pb	R/W	0x0	Polarity of byte lane select for static memory CS1. This power on reset value can be over written through the register interface. When '1', for reads and write, the respective active bits of nMPMCBLSOUT[3:0] are LOW. When '0', for reads, all the bits of nMPMCBLSOUT[3:0] are HIGH and for writes, the respective active bits of nMPMCBLSOUT[3:0] are LOW.
6	-	-	0x0	reserved
5	-	-	0x0	reserved
4	ahb_mpmc_misc_stcs1pol	R/W	0x0	Polarity of static memory CS1. This power on reset value can be over written through the register interface. When '1', it indicates active HIGH chip select and when '0', it indicates an active LOW chip select.
3	ahb_mpmc_misc_stcs0pol	R/W	0x0	Polarity of static memory CS0. This power on reset value can be over written through the register interface. When '1', it indicates active HIGH chip select and when '0', it indicates an active LOW chip select.

Table 555. SYSCREG\_AHB\_MPMC\_MISC (address 0x1300 2864) ...continued

Bit	Symbol	R/W	Reset Value	Description
2	Reserved	-	0x0	Reserved
1	Reserved	-	0x0	Reserved
0	ahb_mpmc_misc_srefreq	R/W	0x0	Self refresh request, when '1' it indicates a self refresh request from the CGU.

Static memory address mode select:

When LOW, it indicates that the static memory addresses should be connected as follows:

When external memory width is 8-bits or 16-bits, EBI\_A[15:0] should be connected to the A[15:0] pins of the static memory device. When memory width (MW field) in MPMCStaticConfigx register is set as 16-bit, LPC315x automatically shifts AHB address to EBI address (EBI\_A[15:0] = AHB[16:1]).

When HIGH, the static memory address should be connected as follows:

- When external memory width is 8-bits, EBI\_A[15:0] should be connected to the A[15:0] pins of the static memory device.
- When external memory width is 16-bits, EBI\_A[15:1] should be connected to the A[14:0] pins of the static memory device and EBI\_A[0] is not used. LPC315x does not automatically shift AHB address to EBI address even when memory width (MW field) in MPMCStaticConfigx register is set as 16-bit.

#### 4.6.2 Dynamic memory delay modes

**Table 556. SYSCREG\_MPMC\_DELAYMODES (address 0x1300 2868)**

Bit	Symbol	R/W	Reset Value	Description
31:18	-	-	-	Reserved
17:12	MPMC_delaymodes (del3)	R/W	110010 (binary)	Configures the amount of delay cells, used for delaying MPMCCLKOUT. This 'clock out' goes to the external SDRAM. See <a href="#">Table 27-557</a> for relation between the programmed value and the amount of delay cells. Only used in clock out delayed strategy.
11:6	MPMC_delaymodes (del2)	R/W	110010 (binary)	Configures the amount of delay cells, between MPMCCLK and MPMCCLKDELAY. This clock is used in Command Delayed strategy. See <a href="#">Table 27-557</a> for the relation between the programmed value and the amount of delay cells.
5:0	MPMC_delaymodes (del1)	R/W	110010 (binary)	Configures the amount of delay cells between MPMCCLK and MPMCFBCLKIN. MPMCFBCLKIN is the feedback clock for SRAM read. See <a href="#">Table 27-557</a> for the relation between the programmed value and the amount of delay cells.

[Table 27-557](#) shows the relation between programmed delaymode value and amount of delay cells.

**Table 557. MPMC delay line settings**

Setting	WC Delay	BC Delay	Setting	WC Delay	BC Delay
00	0.44	0.16			
20	5.12	2.61	30	24.15	10.40
21	6.43	3.14	31	25.46	10.93
22	7.60	3.59	32	26.63	11.38
23	8.91	4.12	33	27.94	11.91
24	10.01	4.61	34	29.04	12.40
25	11.32	5.14	35	30.35	12.93
26	12.49	5.59	36	31.52	13.38
27	13.80	6.12	37	32.83	13.91
28	14.75	6.56	38	33.78	14.35
29	16.06	7.09	39	35.09	14.88
2A	17.23	7.54	3A	36.26	15.33
2B	18.54	8.07	3B	37.57	15.86
2C	19.64	8.56	3C	38.67	16.35

**Table 557. MPMC delay line settings ...continued**

Setting	WC Delay	BC Delay	Setting	WC Delay	BC Delay
2D	20.95	9.09	3D	39.98	16.88
2E	22.12	9.54	3E	41.15	17.33
2F	23.43	10.07	3F	42.46	17.86

The following register is used for the static device0 of the MPMC. It provides that the output enable signal for the static device0 (OE) is split up into two equal portions, with one inactive cycle in the middle. This is needed because some memories do not detect consecutive reads within one OE period.

To use this feature MPMCStaticWaitRd must be  $\geq 1$ .

**Table 558. SYSCREG\_MPMC\_WAITREAD\_DELAY0 (address 0x1300 286C)**

Bit	Symbol	R/W	Reset Value	Description
31:6	-	-	-	Reserved
5	enable_extra_OE_inactive_cycle	R/W	0x0	Enable the extra inactive OE cycle if bit is 1.
4:0	Static_read_wait_counter	R/W	0x1	Program the value that you have programmed in MPMCStaticWaitRd0

The following register is used for the static device1 of the MPMC. It provides that the output enable signal for the static device1 (OE) is split up into two equal portions, with one inactive cycle in the middle. This is needed because some memories do not detect consecutive reads within one OE period.

To use this feature MPMCStaticWaitRd must be  $\geq 1$ .

**Table 559. SYSCREG\_MPMC\_WAITREAD\_DELAY1 (address 0x1300 2870)**

Bit	Symbol	R/W	Reset Value	Description
31:6	-	-	-	Reserved
5	enable_extra_OE_inactive_cycle	R/W	0x0	Enable the extra inactive OE cycle if bit is 1.
4:0	Static_read_wait_counter	R/W	0x1	Program the value that you have programmed in MPMCStaticWaitRd1

### 4.6.3 MPMC CS1 memory width register

**Table 560. SYSCREG\_WIRE\_EBI\_MSIZE\_INIT (address 0x1300 2874)**

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1:0	wire_ebi_msize_init	R/W	0x1	memory width of CS1, ahb_mpmc_misc_stcs1mw[1:0]. This power on reset value can be over written through the register interface. '00' indicates 8-bits, '01' indicates 16-bits and '10' & '11' are reserved. Do not change this register during normal operation.

#### 4.6.4 MPMC testmode registers

**Table 561. MPMC\_TESTMODE0 (address 0x1300 2878)**

Bit	Symbol	R/W	Reset Value	Description
31:13	-	-	-	Reserved
12	external_refresh_enable	R/W	0x0	When the External refresh bit is '1', then the external refresh generator will take over the refresh generation of the MPMC.  '0' Normal MPMC refresh method '1' The external refresh generator generates the refresh for the MPMC
11:0	external_refresh_counter_value	R/W	0x0	The value programmed here times 16 times 'base_clk cycle time' is the period of every external refresh.

The value programmed in 'external refresh counter value' will be the timing of the refresh. The clock of the external refresh generator should always be the base\_clock, making the refresh AHB clock independent.

This value can be calculated like this:

- $\text{refresh\_time}/(\text{base\_clk\_period} \times 16)$
- For example, the refresh time is 15  $\mu\text{s}$  and the base\_clock of the SYS\_BASE domain is 60 MHz (16.6 ns period time)
- Calculated:  $15000/(16.6 \times 16) = 56$  (always round downward)

**Table 562. MPMC\_TESTMODE1 (address 0x1300 287C)**

Bit	Symbol	R/W	Reset Value	Description
31:8	-	-	-	Reserved
7:0	high_speed_enable_cnt	R/W	0x0	High speed enable counter for the external refresh generator. The value programmed in this register will determine the amount of clock cycles. The 'hi_speed_enable' towards the CGU will be active at the moment of refresh request. This allows the AHB clock to temporarily run faster while refreshing, which might improve SDRAM power consumption.

## 4.7 Miscellaneous system configuration registers, part2

### 4.7.1 AHB external priority settings

Table 563. AHB0\_EXTPRIO (address 0x1300 2880)

Bit	Symbol	R/W	Reset Value	Description
31:4	-	-	-	Reserved
3	USB_OTG_prio	R/W	0x0	If this bit =1 then USB OTG has higher priority on the AHB bus then the other AHB masters for which this bit is not set.
2	ARM926_Data_bus_prio	R/W	0x0	If this bit =1 then ARM926 Data has higher priority on the AHB bus then the other AHB masters for which this bit is not set.
1	ARM926_Instruction_bus_prio	R/W	0x0	If this bit =1 then ARM926 Instruction has higher priority on the AHB bus then the other AHB masters for which this bit is not set.
0	DMA_prio	R/W	0x0	If this bit =1 then DMA has higher priority on the AHB bus then the other AHB masters for which this bit is not set.

The rules for determining which master is granted for slave x are described in [Section 12–1.2](#).

### 4.7.2 Shadow memory control register

Table 564. SYSCREG\_ARM926\_SHADOW\_POINTER (address 0x1300 2884)

Bit	Symbol	R/W	Reset Value	Description
31:0	ARM926EJS_shadow_pointer	R/W	0x1200 0000	This register is provided to be able to change the memory mapping. The first 4 kB address space of the 32 bit address value programmed in this register is mirrored/shadowed at address 0x0 for ARM926EJS bus master. Note, other bus masters on AHB matrix do not have this re-map logic. The lower 10 bits of the address value should always be zeros. It is freely programmable in increments of 1 kB.

For more information see also [Section 12–1.2](#).

## 4.8 Pin multiplexing registers

**Table 565. SYSCREG\_MUX\_LCD\_EBI\_SEL(address 0x1300 2890)**

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	Mux_LCD_EBI_sel	R/W	0x0	<p>Selects between LCD interface and EBI/MPMC pins.            0: LCD interface            1: EBI/MPMC</p> <p>The pins affected by this register are:            LCD_CSB - MPMC_NSTCS_0            LCD_DB_1 - MPMC_NSTCS_1            LCD_DB_0 - MPMC_CLKOUT            LCD_E_RD - MPMC_CKE            LCD_RS - MPMC_NDYCS            LCD_RW_WR - MPMC_DQM_1            LCD_DB_2 - EBI_A_2            LCD_DB_3 - EBI_A_3 I            LCD_DB_4 - EBI_A_4 I            LCD_DB_5 - EBI_A_5 I            LCD_DB_6 - EBI_A_6            LCD_DB_7 - EBI_A_7            LCD_DB_8 - EBI_A_8            LCD_DB_9 - EBI_A_9            LCD_DB_10 - EBI_A_10            LCD_DB_11 - EBI_A_11            LCD_DB_12 - EBI_A_12            LCD_DB_13 - EBI_A_13            LCD_DB_14 - EBI_A_14            LCD_DB_15 - EBI_A_15</p>

**Table 566. SYSCREG\_MUX\_GPIO\_MCI\_SEL (address 0x1300 2894)**

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	Mux_GPIO_MCI_sel	R/W	0x0	<p>Selects between GPIO and MCI pins.            0: GPIO            1: MCI</p> <p>The pins affected by this register are:            GPIO5 - MCI_CLK            GPIO6 - MCI_CMD            GPIO7 - MCI_DAT_0            GPIO8 - MCI_DAT_1            GPIO9 - MCI_DAT_2            GPIO10 - MCI_DAT_3</p>

**Table 567. SYSCREG\_MUX\_NAND\_MCI\_SEL (address 0x1300 2898)**

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	Mux_NAND_MCI_sel	R/W	0x0	Selects between NAND1 and MCI pins. 0: NAND 1: MCI

The pins are affected by this register are:  
 NAND\_RYBN0-MCI\_DAT4  
 NAND\_RYBN1-MCI\_DAT5  
 NAND\_RYBN2-MCI\_DAT6  
 NAND\_RYBN3-MCI\_DAT7

**Table 568. SYSCREG\_MUX\_UART\_SPI\_SEL (address 0x1300 289C)**

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	Mux_UART_SPI_sel	R/W	0x0	Selects between SPI and UART pins. 0: UART 1: SPI

The pins affected by this register are:  
 UART\_CTS\_N - SPI\_CS\_OUT1  
 UART\_RTS\_N - SPI\_CS\_OUT2

**Table 569. SYSCREG\_MUX\_I2STX\_IPINT\_SEL (address 0x1300 28A0)**

Bit	Symbol	R/W	Reset Value	Description
31:1	-	-	-	Reserved
0	Mux_I2STX_0_PCM_sel	R/W	0x0	Selects between I2STX_0 and IPINT_1 pins. 0: I2STX_0 1: PCM

The pins affected by this register are:  
 I2STX\_CLK0 - PCM\_DB  
 I2STX\_DATA0 - PCM\_DA  
 I2STX\_WS0 - PCM\_DCK  
 I2STX\_BCK0 -PCM\_FSC.

### 4.9 Pad configuration registers

**Table 570. SYSCREG\_padname\_PCTRL (addresses 0x1300 28A4 to 0x1300 2A28)**

Bit	Symbol	R/W	Reset Value	Description
31:2	-	-	-	Reserved
1	SYSCREG_<padname>_PCTRL_<padname>_P2	R/W	0x0/0x1	The logic pin P2 of the pad. The reset value depends on the pad. The reset value is 0x1 for all pads except for I2C_SDA1 and I2C_SCL1.
0	SYSCREG_<padname>_PCTRL_<padname>_P1	R/W	0x0/0x1	The logic pin P1 of the pad. The reset value depends on the pad (see table below). The reset value is 0x0 for all pads except from GPIO0 and GPIO1.

See also [Table 27-571](#) for explanation of the P1 and P2.

**Table 571. Logic Behaviour of Input Cell**

Input					Output		Mode
IO <sup>[1]</sup>	EN	P1	P2	IO	Z1		
Bond pad input state	EN = disable output driver			Bond pad output	Input to chip core logic		
L <sup>[2]</sup>	H	- <sup>[4]</sup>	-	L	L	Receiving	
H	H	-	-	H	H	Receiving	
Z	H	L	L	h <sup>[3]</sup>	H	Pull-up	
Z	H	L	H	Z	5	Plain input	
Z	H	H	L	rpt	RPT	Repeater	
Z	H	H	H	I	L	Weak pull-down	

- [1] Externally driven.
- [2] Capital letters indicate strong signal
- [3] Lower case letters indicate a weak signal
- [4] Dash (-) Indicates any or do not care.
- [5] ZI is driven to the same logic state as IO.

**Table 572. SYSCREG\_ESHCTRL\_SUP4 (address 0x1300 2A2C)**

Bit	Symbol	R/W	Reset value	Description
31:1	-	-	-	Reserved
0	SYSCREG_ESHCTRL_SUP4	R/W	0x1	This bit controls the performance of all pads which belong to the supply domain SUP4 (Nandflash and EBI pads). SUP4 has a typical supply voltage of 1.8 V or 3.3 V. 0 : high speed-performance 1: less switching noise. (To obtain the same speed-performance at the supply voltage of 1.8 V as 3.3 V, this bit has to be set at 0x0.)

**Table 573. SYSCREG\_ESHCTRL\_SUP8 (address 0x1300 2A30)**

Bit	Symbol	R/W	Reset value	Description
31:1	-	-	-	Reserved
0	SYSCREG_ESHCTRL_SUP8	R/W	0x1	This bit controls the performance of all pads which belong to the supply domain SUP8 (LCD interface/SDRAM pads). SUP8 has a typical supply voltage of 1.8 V or 3.3 V. 0 : high speed-performance 1: less switching noise (To obtain the same speed-performance at the supply voltage of 1.8V as 3.3 V, this bit has to be set at 0x0.)

## 1. Introduction

PCM (Pulse Code Modulation) is a very common method used for transmitting analog data in digital format. Most common applications of PCM are Digital audio as in Audio CD and computers, digital telephony and digital videos.

The IOM (ISDN Oriented Modular) interface is primarily used to interconnect telecommunications ICs providing ISDN compatibility. It delivers a symmetrical full-duplex communication link containing user data, control/programming, and status channels.

The combined PCM/IOM interface is also called IPINT in the following text.

### 1.1 Features

- Four wire serial interface.
- Can function in both Master and Slave modes.
- Supports:
  - PCM: Pulse code modulation. Single clocking physical format.
  - MP PCM: Multi-Protocol PCM. Configurable direction per slot.
  - IOM-2: Extended ISDN-Oriented modular. Double-clocking physical format.
- Twelve eight bit slots in a frame with enabling control per slot.
- Internal frame clock generation in master mode.
- Receive (RX) and Transmit (TX) DMA handshaking using a request/clear protocol.
- Interrupt generation per frame.

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock signals

Table 574. Clock signals of the PCM

Clock name	I/O	Source/ destination	Description
PCM_PCLK	I	CGU	PCM Clock. Used to synchronize the DMA handshake signals, needs to be continuously running.
PCM_APB_PCLK	I	CGU	APB Interface clock. Used to perform register accesses and is gated with psel.
PCM_CLK_IP	I	CGU	Clock for Timing.
PCM_FCS_IN	I	on pin ml2STX_BCK0/ PCM_FSC	8 kHz frame sync signal in slave mode

Table 574. Clock signals of the PCM

Clock name	I/O	Source/ destination	Description
PCM_FCS_OUT	O	on pin mI2STX_BCK0/ PCM_FSC	8 kHz frame sync signal in master mode
PCM_DCLK_IN	I	on pin mI2STX_WS0/ PCM_DCLK	Data clock input in slave mode
PCM_DCLK_OUT	O	on pin mI2STX_WS0/ PCM_DCLK	Data clock output in master mode
CLK_IP_ENABLE	O	CGU	Enable for PCM_PCLK. This signal is connected internally to CGU module to tell CGU when to gate & not gate PCM_CLK_IP clock.

### 2.1.2 Pin connections

Table 575. Pins of the PCM interface

Name	Type	Description
mI2STX_DATA0\ PCM_DA <sup>[2]</sup>	I/O	Serial data input/output
mI2STX_CLK0\ PCM_DB <sup>[2]</sup>	I/O	Serial data input/output
mI2STX_WS0\ PCM_DCLK <sup>[2]</sup>	I/O	Data clock input when in slave mode or output when in master mode
mI2STX_BCK0\ PCM_FSC <sup>[2]</sup>	I/O	8 KHz clock synchronization input when in slave mode or output when in master mode.

[1] Directions of PCM\_DA and PCM\_DB are configured using TYP\_DO\_IP in CNTL0 register (see [Table 28–579](#)). PCM\_DCLK and PCM\_FSC are configured using TYP\_OD in CNTL0 register (see [Table 28–579](#)).

[2] The PCM pins are multiplexed with the I2S-bus pins.

### 2.1.3 Interrupt requests

The IPINT provides an interrupt through event router module to the ARM processor to allow voice processing. It is generated when all new data from the PCM/IOM ports are available in the associated registers.

### 2.1.4 Reset signals

The CGU provides a synchronous reset for the PCM\_PCLK clock domain (PNRES) and an asynchronous reset (RESET\_ASYNC) and synchronous reset (RESET) for the PCM\_CLK\_IP clock domain.

Asynchronous reset signals go only to asynchronous reset on flip/flops. There are no internally generated asynchronous reset signals.

### 2.1.5 DMA transfer signals

Table 576. DMA signals of the IPINT

Name	Type	Description
DMAREQ_TX	O	Request to DMA for transmit data
DMAREQ_RX	O	Request to DMA for receive data

### 3. Register overview

Table 577. Register overview: PCM/IOM (register base address 0x1500 0000)

Name	R/W	Address offset	Description
GLOBAL	R/W	0x000	Global register
CNTL0	R/W	0x004	Control register 0
CNTL1	R/W	0x008	Control register 1
HPOUT[0]	W	0x00C	Transmit data register 0
HPOUT[1]	W	0x010	Transmit data register 1
HPOUT[2]	W	0x014	Transmit data register 2
HPOUT[3]	W	0x018	Transmit data register 3
HPOUT[4]	W	0x01C	Transmit data register 4
HPOUT[5]	W	0x020	Transmit data register 5
HPIN[0]	R	0x024	Receive data register 0
HPIN[1]	R	0x028	Receive data register 1
HPIN[2]	R	0x02C	Receive data register 2
HPIN[3]	R	0x030	Receive data register 3
HPIN[4]	R	0x034	Receive data register 4
HPIN[5]	R	0x038	Receive data register 5
CNTL2	R/W	0x03C	Control register 2

### 4. Register description

Table 578. GLOBAL register (address 0x1500 0000)

Bit	Symbol	R/W	Reset Value	Description
31-5	-	-	-	Reserved
4	DMARXENA BLE	R/W	0	When true DMA rx enabled
3	DMATXENA BLE	R/W	0	When true DMA tx enabled
2	NORMAL	R/W	0	0: Slave single 16bits slot mode <sup>[1]</sup> 1: Normal mode
1	-	-	-	Reserved
0	ON_OFF	R/W	0	When true IPINT is active

- [1] In Slave0 single slot mode there is only one 16-bit PCM slot, and does only support frame sync LF mode as set in CNTL0 TYP\_FRMSYNC. Data is available in hpin[3] (INSLOT[7:6]) and data is sent from hpout[0] (OUTSLOT[1:0]). There needs to be at least 16 PCM\_DCLK clock cycles in one PCM frame and there should be no more then 31 clock cycles. The pcm\_int occurs at the end of the 16 bits, this is after the last bit has been received.

Table 579. CNTL0 register (address 0x1500 0004)

Bit	Symbol	R/W	Reset Value	Description
31-15	-	-	-	Reserved
14	MASTER	R/W	0	PCM/IOM master mode. 0: PCM is slaved to the PCM/IOM port timing. PCM_DCLK and PCM_FCS are inputs. 1: PCM is master on the PCM/IOM port. PCM_DCLK and PCM_FCS are outputs.
13-12	-	-	-	Reserved
11	LOOPBACK	R/W	0	Internal loop-back mode 0: no loop-back selected. 1: data out is internally connected to data in. Data is not re-clocked.
10	TYP_OD	R/W	0	Type of PCM_FCS and PCM_DCLK output port. 0: PCM_FCS and PCM_DCLK use open-drain. 1: PCM_FCS and PCM_DCLK use push-pull.
9-8	TYP_DO_IP	R/W	0	Type of PCM/IOM data output ports. 00: PCM/IOM port outputs set to tri-state 01: Outputs use open-drain and are set to tri-state outside transmission. 10: Outputs use push-pull and are set to tri-state outside transmission 11: Outputs use push-pull and are always driven
7-6	TYP_FRMSY NC	R/W	0	Shape of frame synchronization signal. 00: Short frame-sync FR enclosing the first rising clock edge 01: Short frame-sync FF enclosing the first falling clock edge 10: Short frame-sync LF enclosing the last falling clock edge 11: Long frame-sync over the first slot (8 bit)
5-3	CLK_SPD	R/W	0	Port frequency selection PCM: 1 clock cycle per bit 000: 512kHz, 64 bits clocked per frame of 125 ms 001: 768kHz, 96 bits clocked per frame 010: 1.536 MHz, 192 bits clocked per frame 011: 2.048 MHz, 256 bits clocked per frame IOM: 2 clock cycles per bit 100: 512kHz, 32 bits clocked per frame 101: 768kHz, 48 bits clocked per frame 110: 1.536 MHz, 96 bits clocked per frame 111: 4.096 MHz, 256 bits clocked per frame
2-0	-	-	-	Reserved

**Table 580. CNTL1 register (address 0x1500 0008)**

Bit	Symbol	R/W	Reset Value	Description
31-12	-	-	-	Reserved
11-0	ENSLT	R/W	0	Enable PCM/IOM Slots, one control bit for each slot.

**Table 581. HPOUT[5:0] registers (addresses 0x1500 000C to 0x1500 0020)**

Bit	Symbol	R/W	Reset Value	Description
31-16	-	-	-	Reserved
15-0	HPOUT[5:0]	W	0	For each two slots a 16 bits transmit data register exists. $\{ \text{slot}[i * 2 + 1], \text{slot}[i * 2] \} = \text{hpout}[i]$

**Table 582. HPIN[5:0] registers (addresses 0x1500 0024 to 0x1500 0038)**

Bit	Symbol	R/W	Reset Value	Description
31-16	-	-	-	Reserved
15-0	HPIN[5:0]	R	0	For each two slots a 16 bits receive data register exists. $\text{hpin}[i] = \{ \text{slot}[i * 2 + 1], \text{slot}[i * 2] \}$

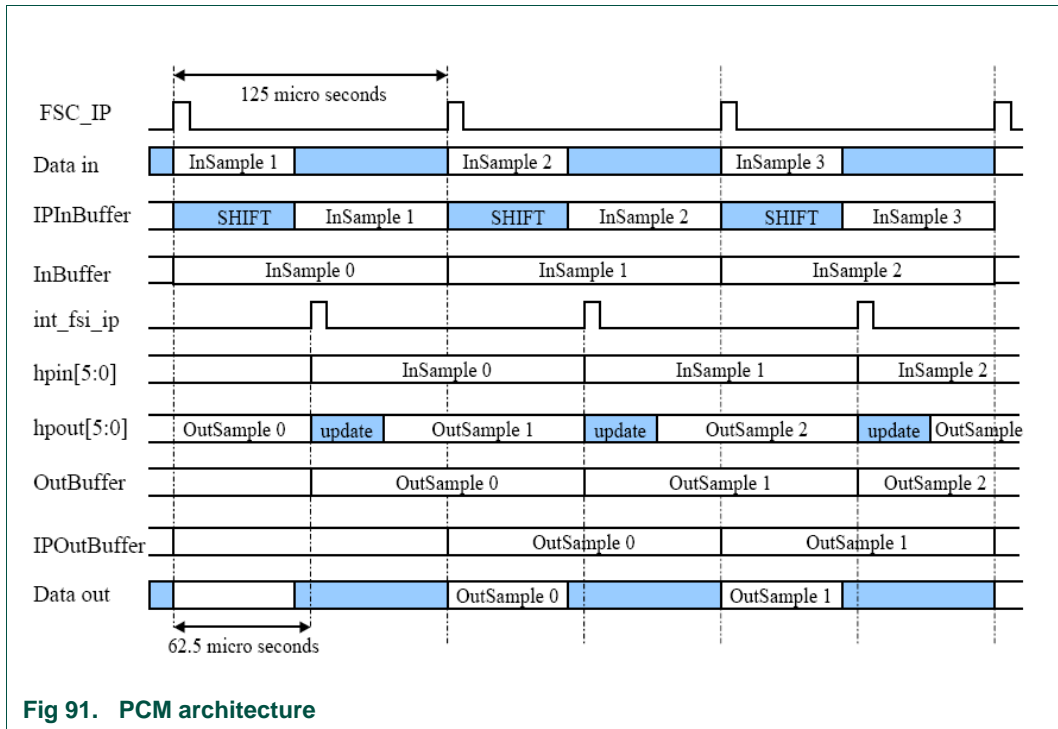

The PCM/IOM bus data bits are numbered from 0 (first, i.e. earliest bit) to N.

**Table 583. CNTL2 register (address 0x1500 003C)**

Bit	Symbol	R/W	Reset Value	Description
31-12	-	-	-	Reserved
11-0	SLOTDIRINV	R/W	0	PCM A/B port configuration One control bit for each slot. 0: A is an output, B is an input 1: A is an input, B is an output

## 5. Functional description

### 5.1 Architecture

The PCM provides an interrupt, `pcm_int`, to the ARM processor to allow voice processing. It is generated when all new data from the PCM/IOM ports are available in the associated registers.

Alternatively the RX and/or TX DMA request/clear handshake signals can be enabled. The request is then generated after the rising edge of `pcm_int` and is synchronized to `pcclk`; it will remain high until a clear signal is given.

In the receive direction, the first 96-bits of each IP frame are clocked in by the IPINT and shifted into the IPInbuffer. There they are held until they are copied into the INBuf at the start of the next IP frame. From there, data is forwarded to the HPIN register. An interrupt, `pcm_int`, to the Host Processor is generated halfway the frame, thus ensuring stable data. At this time the processor may read and process PCM/IOM data from the HPIN register.

In the transmit direction the `pcm_int` interrupt to the Host Processor is generated allowing it to manually write data into the HPOUT register. With the next `pcm_int` pulse, the data in the HPOUT register is latched into the OutBuffer. From there, they are transferred to the IPOutBuffer shift register with the start of the next IP frame and clocked serially out of the IP port.

All transfers are synchronized to `clk_ip`, hence no violation is possible and data integrity is guaranteed. The IPINT control register configures the PCM/IOM port, including operation, master/slave mode, shape of synchronization signal, port frequency selection and PCM/IOM data length.

## 5.2 Operation

The PCM\_DA and PCM\_DB are bi-directional ports of PCM/IOM INTERFACE IPINT, which are connected to two 1 bit inout lines A and B. The A and B I/O lines may be jointly programmed as:

- 1.A input and B output
- 2.A output and B input

SLOTDIRINV bit in register CNTL2 controls this direction. The SLOTDIRINV configuration allows Multi Protocol-PCM transmission.

The PCM\_FCS is an 8kHz-framing signal for synchronizing data transmission on DA and DB, i.e. frame period will always be 125 microseconds. The rising edge of PCM\_FCS gives the time reference for the first bit transmitted in the first slot of a frame. The IPINT can work either in master mode (bus timing is provided by IPINT) or in slave mode (IPINT is synchronized to the timing received from the bus).

The number of slots per frame depends on the selected data rate, however each slot will always contain 8 data bits. The IPINT handles the first 96 bits of PCM/IOM frames. Processing 96 bits in a PCM/IOM frame allows accessing maximum of 12 channels (slots) to 8 bit devices. For longer frames all bits after the 96th are ignored.

Data is transmitted in 16-bit word order:

Data (A or B) send = {hpout[5], hpout[4], hpout[3], hpout[2], hpout[1], hpout[0]}

Where  $hpout[i] = \{slot[i * 2 + 1], slot[i * 2]\}$  are registers accessible via the APB bus.

Transmitted data in order (left to right, top to bottom) is.

{slot1, slot0}: hpout[0][15], hpout[0][14], ..., hpout[0][1], hpout[0][0].

{slot3, slot2}: hpout[1][15], hpout[1][14], ..., hpout[1][1], hpout[1][0]

...

{slot9, slot8}: hpout[4][15], hpout[4][14], ..., hpout[4][1], hpout[4][0]

{slot11, slot10}: hpout[5][15], hpout[5][14], ..., hpout[5][1], hpout[5][0]

Received data is stored into six 16-bit hpin registers in the same order as their hpout counterparts, i.e.  $hpout[i] \Rightarrow transmit \Rightarrow hpin[i] \dots$

However, if the frame size is smaller than 12 slots then the lower hpout slots are not transmitted, i.e.  $hpout[i + (12 - frameslots) / 2] \Rightarrow transmit \Rightarrow hpin[i]$ . As an example, if a 64-bit frame is configured then transmission starts from hpout[2] up to hpout[5] and is received starting from hpin[0] up to hpin[3].

PCM\_DCLK is a data clock. Its frequency is twice the selected data rate in IOM mode. In PCM mode, the PCM\_DCLK frequency is equal to the data rate. Refer to CLK\_SPD bits in CNTL0 register.

The IPINT can work at several bit rates; these are specified in the table below. The bit rate is selected by writing appropriate 3-bit code into the Control Register 0.

Table 584. Bit Rates and Modes

IOM (KBIT/SEC)	PCM (Kbit/sec)	MODE
	128 to 248	Slave only
256	512	Master and slave
384	768	Master and slave
768	1536	Master and slave
2048	2048	Master and slave

The availability data is signalled to the processor by a single interrupt, `pcm_int`, for every PCM/IOM frame. And by two sets of DMA handshaking signals, one for incoming data (RX) and one for outgoing data (TX), if enabled. DMA handshaking involves following steps.

- If data is available and/or required a `dmareq_rx` or `dmareq_tx` is set high
- When a data access is performed to the corresponding register set, i.e. `hpout` for TX and `hpin` for RX, it becomes possible to clear the DMA request
- `dmaclr_rx/tx` becomes high the request will be removed.

The IPINT supports the physical data formats for PCM (one clock cycle per bit) or IOM (two clock cycles per bit). Any potentially required data structuring (e.g. monitor channel for IOM) has to be performed by the processor. The connection between the IP port and the different blocks and channels needs to be handled by the Processor by copying data between the IPINT registers and the different registers associated with each block and channel.

### 5.3 PAD Configuration

Pad configuration is controlled by CNTL0 register. Bits TYP\_DO\_IP (9:8) in CNTL0 control the type of data output port. Pads can be configured in tristate, push pull or open drain.

### 5.4 Bi-directional data line configuration

The IPINT allows configuration of data direction for both data lines on a slot-by-slot basis where one of the lines must be set as input and the other one as output.

- Time slots are activated by setting relevant bits of ENSLT in register cntl1. For inactive slots (ENSLT[i] = 0), both data lines will be set to HighZ. When switching the direction of the data lines at least one inactive slot must be taken into account as guard space.
- The direction of the data lines for each of the twelve slots is configured by bits of SLOTDIRINV in register cntl2.
- Bi-directional data line configuration is possible only in short frame sync.
  - cntl0 TYP\_FRMSYNC = 10: LF, first bit transmitted on the cycle after Frame Sync (PCM\_FCS) is active.
- The following must be taken into account when using the IPINT in bi-directional mode.
  - The SLOTDIRINV[i], ENSLT[i] applies from the first cycle to the last cycle of a given slot i. The first slot starts, i.e. the first bit is transmitted, on the cycle occurring after Frame Sync active cycle. The data line (DA or DB) that is configured as Output is tri-stated during guard slots and during the idle frame period (see [Figure 28–93](#)).

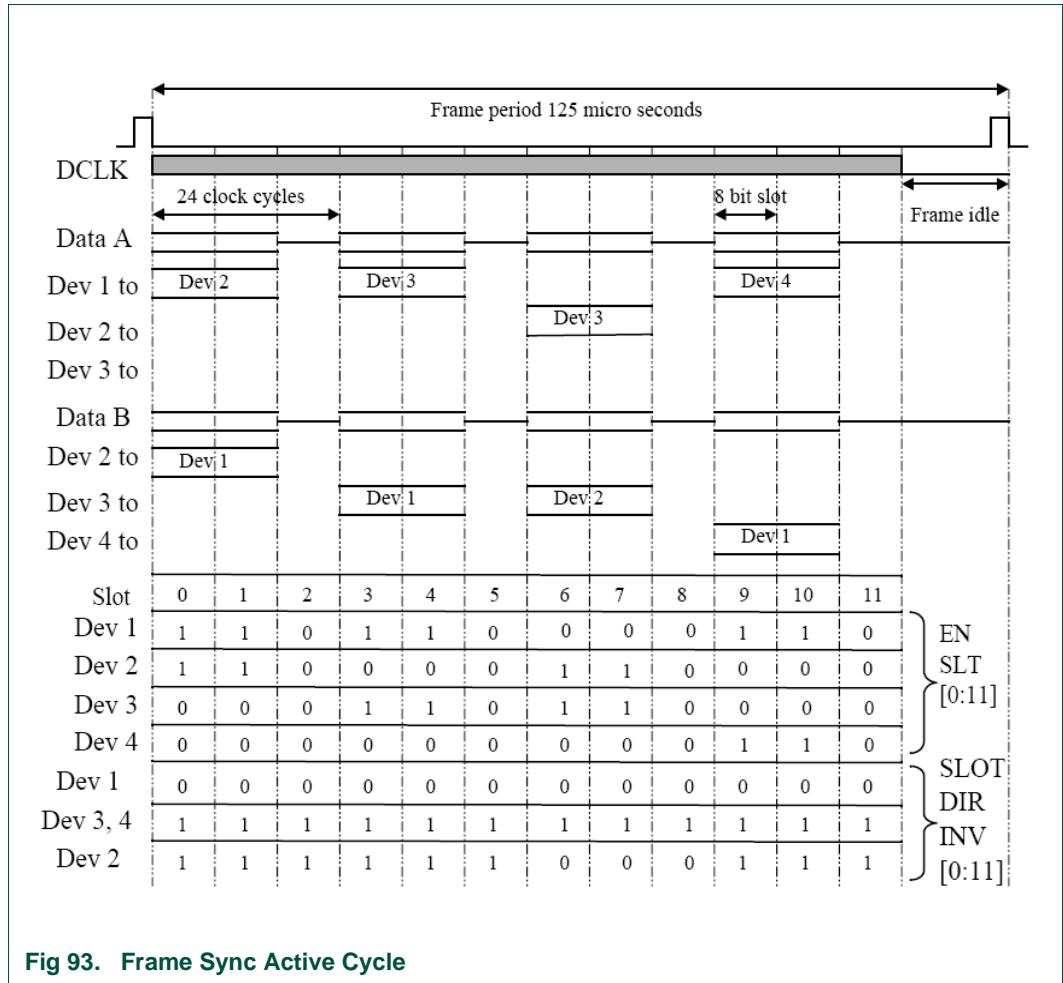

Fig 93. Frame Sync Active Cycle

Figure 28–93 shows an example of communication between 4 devices using bi-directional PCM data lines. Each device has its DA pin connected to a common A line and DB pin connected to a common B line. Data is transferred in words of 16-bit (2 slots per word). Between each data word one guard slot is used to switch the direction of the data lines. This slot scheduling is not exclusive; it depends on the number of devices that are connected to the data lines A and B and which pair of devices is communicating at each slot. Therefore, for a given device the DA and DB lines are able to switch from input to output and output to input depending with which devices it has to communicate during a certain slot. The user must ensure that only one device is transmitting on a PCM data line at the time.

5.5 Timing

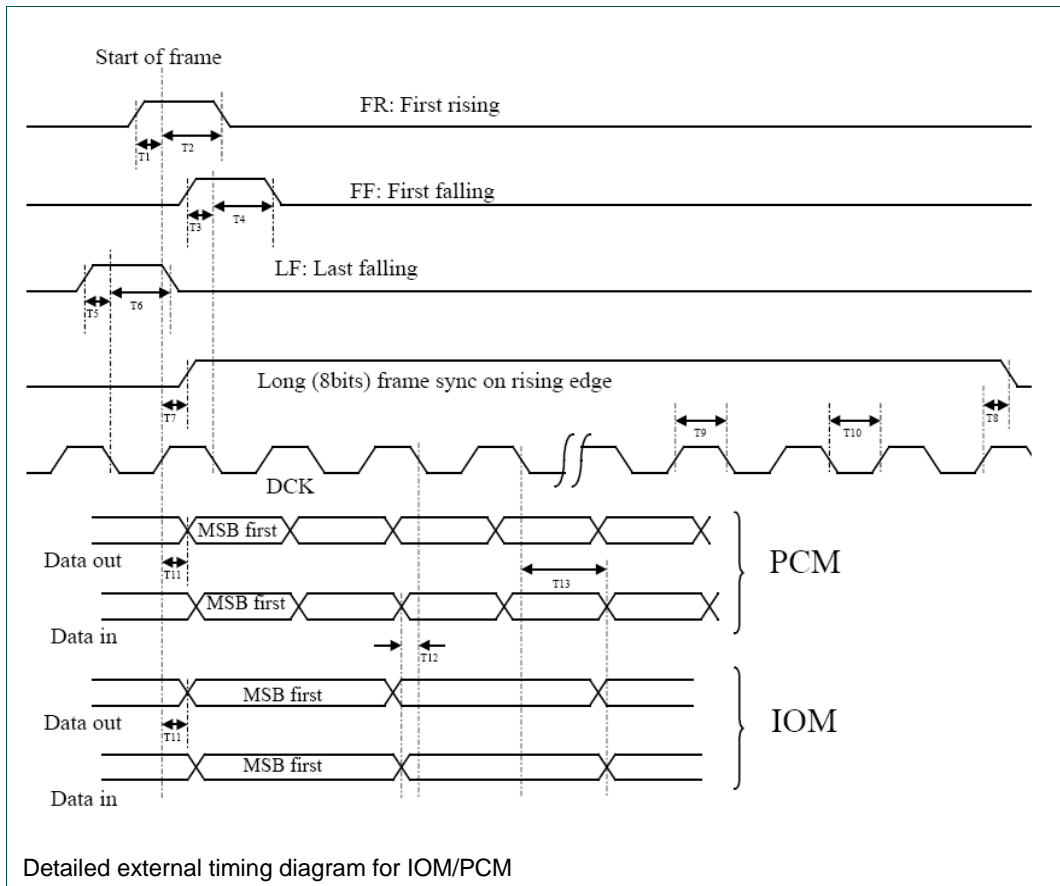

Table 585. PCM Port Timing

Symbol	Description	MIN (NS)	MAX (NS)
T1	Frame sync (short FR) to clock rising setup time	80	N.A
T2	Frame sync (short FR) to clock rising hold time	50	N.A
T3	Frame sync (short FF) to clock falling setup time	80	N.A
T4	Frame sync (short FF) to clock falling hold time	50	N.A
T5	Frame sync (short LF) to clock falling setup time	80	N.A
T6	Frame sync (short LF) to clock falling hold time	50	N.A
T7	Frame sync (long) rising edge delay	N.A	20
T8	Frame sync (long) falling edge hold time	N.A	20
T9	PCM Clock high time	80	N.A
T10	PCM Clock low time	80	N.A
T11	PCM Data out valid delay	N.A	60
T12	PCM Data in setup time	20	N.A
T13	PCM Data in hold time	50	N.A

Table 586. IOM Port Timing

Symbol	Description	MIN (NS)	MAX (NS)
T1	Frame sync (short FR) to clock rising setup time	70	N.A
T2	Frame sync (short FR) to clock rising hold time	40	N.A
T3	Frame sync (short FF) to clock falling setup time	70	N.A
T4	Frame sync (short FF) to clock falling hold time	40	N.A

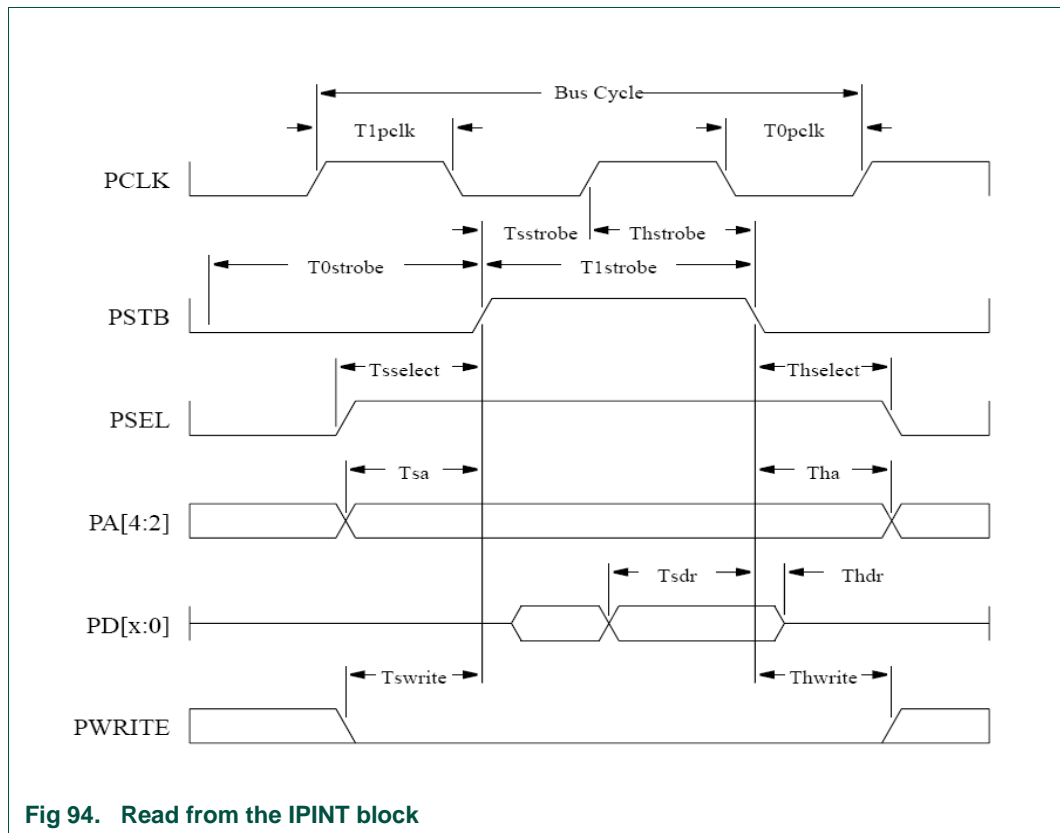

Fig 94. Read from the IPINT block

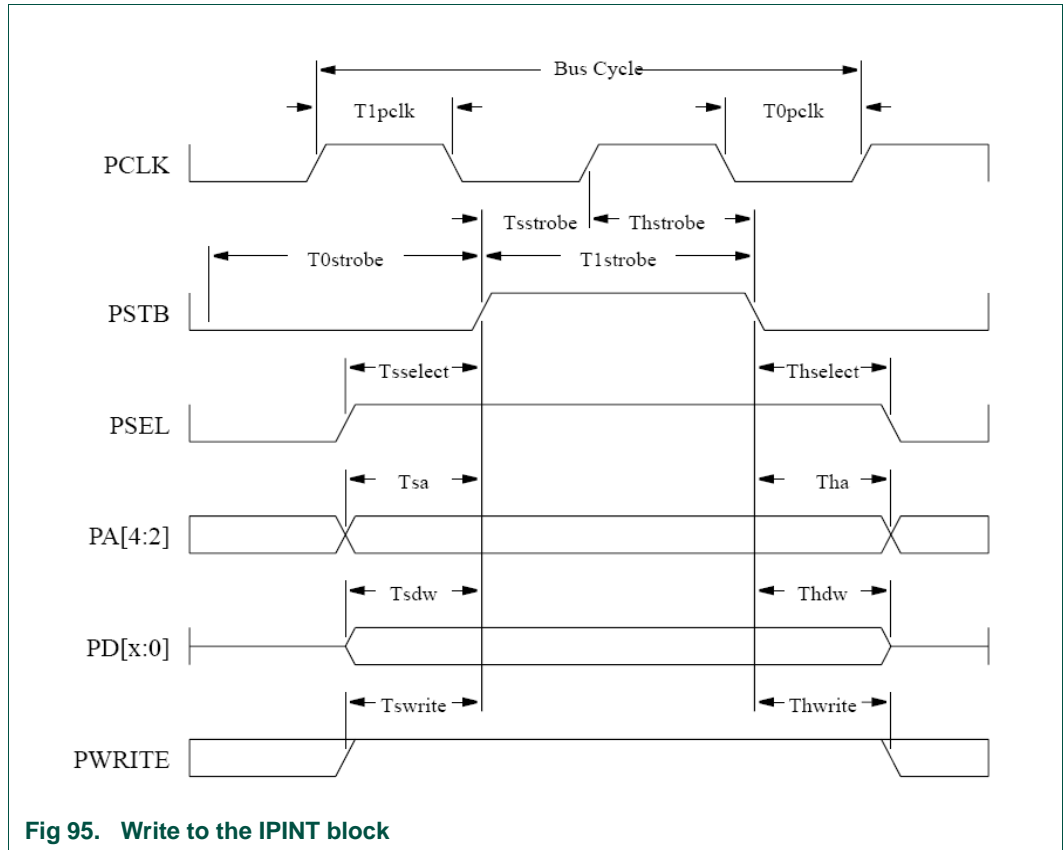

Fig 95. Write to the IPINT block

Table 587. Timing Parameters

Parameter Name	Description
T1pclk	Minimum required high time for PCLK.
T0pclk	Minimum required low time for PCLK.
T1strobe	Minimum required high time for PSTB.
T0strobe	Minimum required high time for PSTB.
Tsstrobe	Minimum required setup time for PSTB.
Thstrobe	Minimum required hold time for PSTB.
Tsselect	Minimum required setup time for PSEL.
Thselect	Minimum required hold time for PSEL.
Tsa	Minimum required setup time for PA[4:2].
Tha	Minimum required hold time for PA[4:2].
Tsdr	Minimum provided setup time for a PD[31:0] read.
Thdr	Minimum provided hold time for a PD[31:0] read.
Tsdw	Minimum required setup time for a PD[31:0] write.
Thdw	Minimum required hold time for a PD[31:0] write.
Tswrite	Minimum required setup time for PWRITE.
Thwrite	Minimum required hold time for PWRITE.

## 5.6 Timing controller

The IPINT may operate as timing master or slave on the PCM/IOM bus. When being configured as PCM/IOM slave, it is synchronized to the PCM\_FCS signal received from the PCM/IOM bus. In the PCM/IOM master configuration, the IPINT generates the PCM\_FCS signal.

The signal pcm\_int is used to synchronize other blocks on the chip to the PCM/IOM timing. This signal is obtained by counting half the frame period to ensure data stability during data transfers towards/from the host processor and/or DMA controller.

Frame bit timing is governed by the internally generated signal dclk. In master mode the IPINT will generate dclk by dividing clk\_ip towards the desired frequency using a fractional divider. CLK\_IP must be equal to 24MHz. In slave mode DCK\_IP from padcell will be used as dclk.

**Table 588. IPINT clock division schemes**

DCLK FREQUENCY	CLK_IP (24MHZ) DIVISION FACTOR	X	Y
512 kHz	375/8	375	16
768 kHz	125/4	125	8
1.536 MHz	125/8	125	16
2.048 MHz	375/32	375	64
4.096 MHz	375/64	375	128

## 6. Power optimization

The PCM\_CLK\_IP and PCM\_APB\_PCLK can be clock gated. For this, matching CGU registers have to be programmed.

## 1. Introduction

---

The I2S bus provides a standard communication interface for digital audio applications. The LPC315x includes two I2S interfaces; I2S0 and I2S1.

On the LPC3152/54 the I2S1 interface is internally connected to the analog die audio codec.

The I2S bus specification defines a 3-wire serial bus, having one data, one clock, and one word select signal. The basic I2S connection has one master, which is always the master, and one slave. The I2S interface on the LPC315x provides a separate transmit and receive channel.

### 1.1 Features

The I2S0/1 interfaces have the following features:

- Audio interfaces compatible with the I2S standard.
- The I<sup>2</sup>S0/1 receive interfaces support master and slave mode.
- The I<sup>2</sup>S0/1 transmit interfaces support master mode.
- Support LSB justified words of 16, 18, 20, and 24 bits.
- Support a configurable number of bit clock periods per Word Select period (up to 128 bit clock periods).
- Support DMA transfers.
- Transmit FIFO or receive FIFO of 4 stereo samples.
- Support single 16-bit transfers to/from the left or right FIFO.
- Support single 24-bit transfers to/from the left or right FIFO.
- Support 32-bit interleaved transfers, with the lower 16 bits representing the left audio sample, and the higher 16 bits representing the right audio sample.
- Support two 16-bit samples audio samples combined in a 32-bit word (2 left or 2 right samples) to reduce bus load.
- Provide maskable interrupts for audio status. (FIFO underrun / overrun / full / half\_full / not empty for left and right channel separately).

## 2. General description

---

The I2S transfers serial data out via the transmit channel and serial data in via the receive channel. These blocks have a four word FIFO and support both DMA flow control and interrupts.

The I2S interfaces support the following formats: I2S, LSB16, LSB18, LSB20, and LSB24. The I2SRX interfaces generate a NEWSAM flag indicating that a new audio sample is valid. For the NEWSAM flag, a dedicated WS signal is provided which is connected to an edge detector that generates this NEWSAM. This NEWSAM is used for both I2STX outputs, which means that this system can only operate on a single sampling frequency.

## 2.1 Interface description

### 2.1.1 Clock signals

Table 589. Clock signals of the I2S block

Clock Name	I/O	Source/Destination	Description
I2C_CFG_PCLK	I	CGU	APB related clock. All registers in the I2C_config block run on this clock.
EDGE_DET_PCLK	I	CGU	APB related clock. All registers in the edge_det block run on this clock.
I2STX_FIFO_0_PCLK	I	CGU	APB related clock. All registers in the I2STX_FIFO_0 block run on this clock.
I2STX_FIFO_1_PCLK	I	CGU	APB related clock. All registers in the I2STX_FIFO_1 block run on this clock.
I2SRX_FIFO_0_PCLK	I	CGU	APB related clock. All registers in the I2SRX_FIFO_0 block run on this clock.
I2SRX_FIFO_1_PCLK	I	CGU	APB related clock. All registers in the I2SRX_FIFO_1 block run on this clock.
I2STX_IF_0_PCLK	I	CGU	APB related clock. sysclk of the I2STX_IF_0 runs on this APB synchronous clock.
I2STX_IF_1_PCLK	I	CGU	APB related clock. sysclk of the I2STX_IF_1 runs on this APB synchronous clock.
I2SRX_IF_0_PCLK	I	CGU	APB related clock. sysclk of the I2SRX_IF_0 runs on this APB synchronous clock.
I2SRX_IF_1_PCLK	I	CGU	APB related clock. sysclk of the I2SRX_IF_1 runs on this APB synchronous clock.
I2S_EDGE_DETECT_CLK	I	CGU	Sampling frequency clock. Used to generate NEWSAM flag from edge_detection.
I2STX_BCK0_N	I	CGU	I2S Bit Clock. Indicates the number of bits per audio sample. Typically 48 x fs or 64 x fs.
I2STX_WS0	I	CGU	I2S Word Select. Same frequency as I2S_EDGE_DETECT_CLK. 1 stereo sample per WS cycle.
I2STX_CLK0	I	CGU	256fs system clock for external reference.
I2STX_BCK1_N	I	CGU	I2S Bit clock. Indicates the number of bits per audio sample. Typically 48 x fs or 64 x fs.
I2STX_WS1	I	CGU	I2S Word Select. Same frequency as I2STX_WS. One stereo sample per WS cycle.
CLK_256FS	I	CGU	Oversampling clock for the audio DAC and DAC on the analog die.
I2SRX_BCK0	I	Pin	I2S Bit Clock. Input to CGU PLL.
I2SRX_WS0	I	Pin	I2S Word Select. Same frequency as I2S_EDGE_DETECT_CLK. Input to CGU PLL.
I2SRX_BCK1	I	Pin	I2S Bit Clock. PLL may lock to this clock.
I2SRX_WS1	I	Pin	I2S Word Select. Same frequency as I2S_EDGE_DETECT_CLK. Input to CGU PLL.

### 2.1.2 Pin connections

**Table 590. I2S-bus pins**

Name	I/O	Description	LPC3152/54
I2SRX_DATA0	I	I2S Data	pinned out
I2SRX_BCK0	I	I2S Bitclock	pinned out
I2SRX_WS0	I	I2S Word Select	pinned out
I2STX_DATA0	O	I2S Data	pinned out
I2STX_BCK0	O	I2S Bitclock	pinned out
I2STX_WS0	O	I2S Word Select	pinned out
I2STX_CLK0	O	256fs system clock for external reference	pinned out
I2SRX_DATA1	I	I2S Data	internally connected to analog die
I2SRX_BCK1	O	I2S Bitclock	internally connected to analog die
I2SRX_WS1	O	I2S Word Select	internally connected to analog die
I2STX_DATA1	O	I2S Data	internally connected to analog die
I2STX_BCK1	O	I2S Bitclock	internally connected to analog die
I2STX_WS1	O	I2S Word Select	internally connected to analog die
CLK_256FS_O	O	Reference clock for the analog die	internally connected to analog die

### 2.1.3 Interrupt requests

Relevant information about interrupt requests are generated by this module, except for register descriptions. The module describes the interrupt signals, interrupt reasons and how/when they are generated etc.

**Table 591. Interrupt request signals of the I<sup>2</sup>S interface**

Name	Type	Description
I2STX0_IRQ	O	Configurable I2STX0 interrupt request
I2STX1_IRQ	O	Configurable I2STX1 interrupt request
I2SRX0_IRQ	O	Configurable I2SRX0 interrupt request
I2SRX1_IRQ	O	Configurable I2SRX1 interrupt request

**Table 592. Interrupt request sources for I2SRX**

Name	Description
0	FIFO RIGHT underrun
1	FIFO LEFT underrun
2	FIFO RIGHT overrun
3	FIFO LEFT overrun
4	FIFO LEFT full
5	FIFO LEFT half_full
6	FIFO LEFT NOT empty
7	FIFO RIGHT full
8	FIFO RIGHT half_full
9	FIFO RIGHT NOT empty

Table 593. Interrupt request sources for I2STX

Number	Description
0	FIFO right underrun
1	FIFO left underrun
2	FIFO right overrun
3	FIFO left overrun
4	FIFO left full
5	FIFO left half_empty
6	FIFO left empty
7	FIFO right full
8	FIFO right half_empty
9	FIFO right empty

#### 2.1.4 Reset signals

Table 594. Reset signals of the I2S sub modules

Name	Type	Description
PNRES_I2S_CFG_CONFIG	I	I2C_config APB domain reset (active low)
PRESETN	I	I2SRX_FIFO/I2STX_FIFO APB domain reset (active low)
RESET	I	I2SRX_IF/I2STX_IF reset (active high)
EDGE_DET_RST_N	I	Edge detection reset (active low)

#### 2.1.5 DMA transfer signals

For each of the I2STX\_FIFO and I2SRX\_FIFO blocks in the I2S interface the following DMA signals are supplied:

Table 595. I2S DMA signals

Name	Type	Description
DMA_REQ_LEFT	O	Left channel FIFO DMA request
DMA_REQ_RIGHT	O	Right channel FIFO DMA request
DMA_CLR_LEFT	I	Left channel DMA acknowledge
DMA_CLR_RIGHT	I	Right channel DMA acknowledge

Use pin I2STX0\_dma\_req\_left(slave number 6) when transferring interleaved data (INTERLEAVED\_0 address is used as DMA channel destination) using DMA to I2STX0 block. Similarly use I2STX1\_dma\_req\_left(8), I2SRX0\_dma\_req\_left(10) and I2SRX\_dma\_req\_left(12) for transferring interleaved data to I2STX1, I2SRX0 and I2SRX1 blocks.

### 3. Register overview

**Table 596. Register overview of the I2S configuration module (register base address 0x1600 0000)**

Name	R/W	Address offset	Description
I2S_FORMAT_SETTINGS	R/W	0x00	I2S formats
I2S_CFG_MUX_SETTINGS	R/W	0x04	Misc controls
-	-	0x08 - 0x0C	reserved
N_SOF_COUNTER	R/W	0x10	NSOF counter control

**Table 597. Register overview of the I2STX0 interface (register base address: 0x1600 0080)**

Name	R/W	Address offset	Description
LEFT_16BIT	R/W	0x00	16 bits left channel data
RIGHT_16BIT	R/W	0x04	16 bits right channel data
LEFT_24BIT	R/W	0x08	24 bits left channel data
RIGHT_24BIT	R/W	0x0C	24 bits right channel data
INT_STATUS	R/W	0x10	FIFO status register
INT_MASK	R/W	0x14	Interrupt Mask register
LEFT_32BIT_0 .. LEFT_32BIT_7	R/W	0x20-0x3C	2x16 bits left channel data; 16 LSB's represent the first sample
RIGHT_32BIT_0 .. RIGHT_32BIT_7	R/W	0x40-0x5C	2x16 bits right channel data; 16 LSB's represent the first sample
INTERLEAVED_0 .. INTERLEAVED_7	R/W	0x60-0x7C	Interleaved data; upper 16 bits is right

**Table 598. Register overview of the I2STX1 interface (register base address: 0x1600 0100)**

Name	R/W	Address offset	Description
LEFT_16BIT	R/W	0x00	16 bits left channel data
RIGHT_16BIT	R/W	0x04	16 bits right channel data
LEFT_24BIT	R/W	0x08	24 bits left channel data
RIGHT_24BIT	R/W	0x0C	24 bits right channel data
INT_STATUS	R/W	0x10	FIFO status register
INT_MASK	R/W	0x14	Interrupt Mask register
LEFT_32BIT_0 .. LEFT_32BIT_7	R/W	0x20-0x3C	2x16 bits left channel data; 16 LSB's represent the first sample
RIGHT_32BIT_0 .. RIGHT_32BIT_7	R/W	0x40-0x5C	2x16 bits right channel data; 16 LSB's represent the first sample
INTERLEAVED_0 .. INTERLEAVED_7	R/W	0x60-0x7C	Interleaved data; upper 16 bits is right

**Table 599. Register overview of the I2SRX0 interface (register base address: 0x1600 0180)**

Name	R/W	Address offset	Description
LEFT_16BIT	R/W	0x00	16 bits left channel data
RIGHT_16BIT	R/W	0x04	16 bits right channel data
LEFT_24BIT	R/W	0x08	24 bits left channel data

**Table 599. Register overview of the I2SRX0 interface (register base address: 0x1600 0180)**

Name	R/W	Address offset	Description
RIGHT_24BIT	R/W	0x0C	24 bits right channel data
INT_STATUS	R/W	0x10	FIFO status register
INT_MASK	R/W	0x14	Interrupt Mask register
LEFT_32BIT_0 .. LEFT_32BIT_7	R/W	0x20-0x3C	2x16 bits left channel data; 16 LSB's represent the first sample
RIGHT_32BIT_0 .. RIGHT_32BIT_7	R/W	0x40-0x5C	2x16 bits right channel data; 16 LSB's represent the first sample
INTERLEAVED_0 .. INTERLEAVED_7	R/W	0x60-0x7C	Interleaved data; upper 16 bits is right

**Table 600. Register overview of the I2SRX1 interface (register base address: 0x1600 0200)**

Name	R/W	Address offset	Description
LEFT_16BIT	R/W	0x00	16 bits left channel data
RIGHT_16BIT	R/W	0x04	16 bits right channel data
LEFT_24BIT	R/W	0x08	24 bits left channel data
RIGHT_24BIT	R/W	0x0C	24 bits right channel data
INT_STATUS	R/W	0x10	FIFO status register
INT_MASK	R/W	0x14	Interrupt Mask register
LEFT_32BIT_0 .. LEFT_32BIT_7	R/W	0x20-0x3C	2x16 bits left channel data; 16 LSB's represent the first sample
RIGHT_32BIT_0 .. RIGHT_32BIT_7	R/W	0x40-0x5C	2x16 bits right channel data; 16 LSB's represent the first sample
INTERLEAVED_0 .. INTERLEAVED_7	R/W	0x60-0x7C	Interleaved data; upper 16 bits is right

The following rules apply to the I2S registers:

For the I2STX:

Writing to the data registers puts the sample data in the corresponding FIFO's. The I2STX FIFO's are configured as four 32 bits wide words.

For the I2SRX:

Reading from the data registers gets the sample data from the corresponding FIFO's. The I2SRX FIFO's are configured as four 32 bits wide words.

## 4. Register descriptions

## 5. Functional description

- I2SRX0/1 interface:** This part is an I2S decoder with a serial audio input interface to the APB. It generates a parallel data signal for the left and right channels, and a NEWSAM signal. The NEWSAM signal is a strobe/latch signal that indicates that a new audio sample is available on the data lines, by going high for one clock cycle on the same clock edge, as the new data becomes available. The input format can be I2S or LSB justified.
- I2STX0/1 interface:** This part will generate an I2S output data stream and depending on the setting, it will be an I2S or LSB justified output format. The I2STX includes a serial audio output interface to the APB.

- **Edge Detector:** This module creates a NEWSAM signal (which is a latch enable signal) from the I2S\_EDGE\_DETECT\_CLK. This word select is generated by the CGU. This I2S\_EDGE\_DETECT\_CLK is not connected to the pads of the I2STX interfaces.
- **Configuration register block:** This block offers an APB slave interface to various configuration registers.

## 6. Power optimization

In order to save power, disable clocks when block are not used.

## 7. Programming guide

Setup and configure the AudioPLL (PLL0) and Fractional Dividers registers assuming an external 12MHz crystal connected to PLL0:

1. Choose the Sample Frequency  $F_s$ ; for example  $F_s = 44.1$  kHz.
2. In [Table 29–604](#), we can see that for  $F_s = 44.1$  kHz, the Fractional Divider 17 should be loaded with the value 256 (the column header established the value to be loaded into FracDiv17), while the Output Frequency of the PLL0 should be  $F_{out} = 11.2896$  MHz (column  $F_{out}$  of the same row).
  - a. In order to configure the PLL0 for  $F_{out} = 11.2896$  MHz, the PLL0 parameters are:  $N_{dec} = 131$ ,  $M_{dec} = 29784$ ,  $P_{dec} = 7$ ,  $SELR = 0$ ,  $SELI = 8$ , and  $SELP = 31$ .
  - b. The FracDiv17 register provides the frequency for the WS (Word Select) signal; that is the  $F_s$ . Then, for the BCLK (bit clock signal), if we choose 32-bit clocks per channel, multiplied by two channels (left and right), we will have 64 times the  $F_s$ . That means the FractDiv18 (for I2S\_TX0 and I2S\_RX0) will be  $FracDiv17/64$ . In our example, it would be  $256/64 = 4$ . (The same applies for FracDiv20 which provides the bit clock for I2S\_TX1 and I2S\_RX1).
3. Enable I2S-related clocks in the CGU ([Table 29–589](#)).
4. Configure the interrupt (unmask desired interrupts) according [Table 29–592](#) and [Table 29–593](#), using INT\_MASK register.
5. Configure I2S format in the I2S\_FORMAT\_SETTINGS register according [Table 29–601](#) and [Table 29–602](#). Considerations:
  - For LSB 16-bit format, set the LSB Justified 16-bit (value 4) format in the I2S\_FORMAT\_SETTINGS register and use LEFT\_16BIT and RIGHT\_16BIT registers for data.
  - For LSB 18, 20 or 24 -bit formats, set the LSB Justified 24-bit (value 7) format in the I2S\_FORMAT\_SETTINGS register and use LEFT\_24BIT and RIGHT\_24BIT registers for data.
6. If I2S\_RX is used, configure the module as Master or Slave using the I2S\_CFG\_MUX\_SETTINGS register ([Table 29–603](#)).
7. If NSOF Counter is used, program the edge detection mode using the I2S\_CFG\_MUX\_SETTINGS register ([Table 29–603](#)).
8. To transmit Left Channel data using I2S\_TX, write to any of the following registers: LEFT\_16BIT, LEFT\_24BIT, LEFT\_32BIT\_0 .. LEFT\_32BIT\_7. INTERLEAVED\_0 .. INTERLEAVED\_7 (lower 16 bits).

9. To transmit Right Channel data using I2S\_TX, write to any of the following registers: RIGHT\_16BIT, RIGHT\_24BIT, RIGHT\_32BIT\_0 .. RIGHT\_32BIT\_7. INTERLEAVED\_0 .. INTERLEAVED\_7 (upper 16 bits).
10. To receive Left Channel data using I2S\_RX, read from any of the following registers: LEFT\_16BIT, LEFT\_24BIT, LEFT\_32BIT\_0 .. LEFT\_32BIT\_7. INTERLEAVED\_0 .. INTERLEAVED\_7 (lower 16 bits).
11. To receive Right Channel data using I2S\_RX, read from any of the following registers: RIGHT\_16BIT, RIGHT\_24BIT, RIGHT\_32BIT\_0 .. RIGHT\_32BIT\_7. INTERLEAVED\_0 .. INTERLEAVED\_7 (upper 16 bits).

**Table 604. I2S configuration parameters**

Fractional Divider 17 Value			Frequencies		PLL 0 parameter set-up					
256 Fs	512 Fs	1024 Fs	Fout (MHz)	Fcco (MHz)	Ndec	Mdec	Pdec	SELR	SELI	SELP

## 1. Introduction

---

LPC3152/54 is implemented as a multi-chip module with two side-by-side dies. Most of the analog features of LPC3152/54 are implemented on a separate die referred in this manual as analog die. The block diagram in [Figure 30–96](#) gives an overview of different blocks implemented in the analog die.

- I2C: This block serves as control interface between digital die and analog die. On the digital die this interface is connected to I2C1 pins with slave address of 0x0C. See [Section 24–1](#).
- I2S: This block serves as digital audio interface between digital die and analog die. The I2S interface contains separate Tx and Rx signals which are connected to I2SRX\_1 and I2S\_TX1 interfaces on the digital die. See [Section 29–1](#).
- Audio codec: This block implements an analog input and an analog output (with class AB amplifier). For improved audio quality, a decimator and an interpolator module are integrated. See [Section 31–1](#).
- PSU: The PSU provides the required power supplies to both the analog and digital circuits. See [Section 32–1](#).
- Li-ion Charger: The charger is suitable for charging Li-ion batteries from the USB supply. See [Section 33–1](#).
- USB charge pump: In a system when LPC3152/54 is used in USB host controller role, the USB charge pump, when enabled, generates the required VBUS voltage. See [Section 35–1](#).

## 2. General description

### 2.1 Interface description

#### 2.1.1 Clock signals

The analog die contains an independent CGU which obtains its input clocks from the SYSCLK\_O and CLK\_256FS clocks generated by the digital die CGU. The clock signals for the analog die CGU are internally connected to clock signals on the digital die. The SYSCLK\_O and CLK\_256FS clocks must be enabled in the digital die CGU for communication with the analog die.

From the two input clocks to the analog CGU, several clocks are derived for the various blocks on the analog die (see [Table 30-605](#)).

Table 605. Clock signals of the analog die

Digital die clock	Analog die base clock	Internal analog die clocks, see <a href="#">Figure 30-97</a>	I/O	Source	Description
SYSCLK_O	SYSCLK	lic_clk usbotg_clk dcdc_clk i2c_sysclk	I	CGU	System clock to the analog die. It is connected to the SYSCLK_O clock generated by CGU on the digital die. This clock should always be on for communicating with the analog die.
CLK_256FS	CLK_256FS	i2c_clk_256fs aout_clk_dac ain_clk_adcsys ain_clk_adc1 ain_clk_adc2 int_clk_dsp int_clk_ns dec_clk i2srx_sysclk i2stx_sysclk	I	CGU	Oversampling clock needed for the audio DAC and ADCs. On the digital die this clock is connected to the CLK_256FS clock generated by CGU.
I2STX_BCK1	I2SRX_BCK		I	CGU	I2S receive bit clock. On the digital side this clock is connected to I2STX_BCK1. This clock should always be driven by the digital die.
I2STX_WS1	I2SRX_WS		I	CGU	I2S receive word select clock. On the digital side this pin is connected to I2STX_WS1. This clock should always be driven by the digital die.
I2SRX_BCK1	I2STX_BCK		I	CGU	I2S transmit bit clock. On the digital side this clock is connected to I2SRX_BCK1. This clock should always be driven by digital die.
I2STX_WS1	I2STX_WS		I	CGU	I2S transmit word select clock. On the digital side this clock is connected to I2SRX_WS1. This clock should always be driven by the digital die.

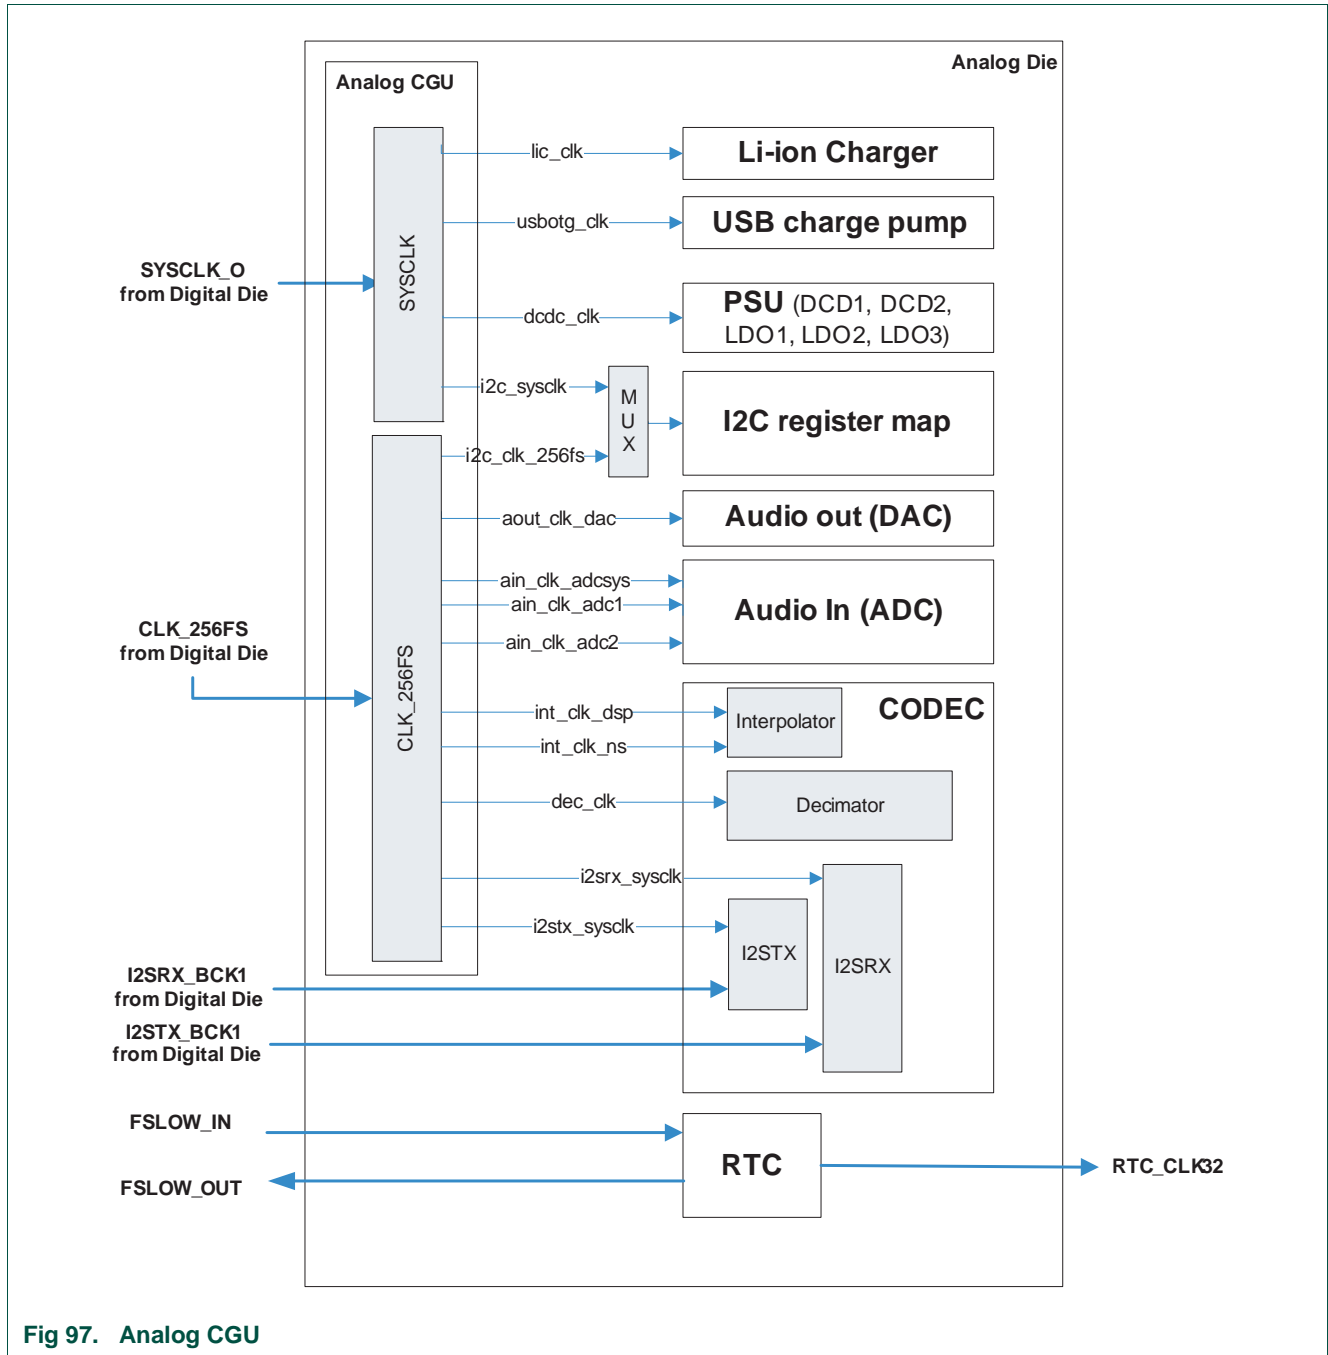

Fig 97. Analog CGU

## 2.2 Pin connections

### 2.2.1 External pins

External pin connections for the various blocks of the analog die are described in the following chapters.

**Table 606. Analog die external pin connections**

Name	Type	Description
<b>External pins common to digital and analog dies</b>		
RSTIN_N	DI	System Reset Input (active LOW)
TDO	DO	JTAG Data output
<b>External pins of the analog die</b>		
Audio pins - analog input pins		see <a href="#">Table 31–633</a>
Audio pins - analog output pins		see <a href="#">Table 31–636</a>
PSU pins		see <a href="#">Table 32–641</a>
Li-ion charger pins		see <a href="#">Table 33–644</a>
RTC pins		see <a href="#">Table 34–647</a>
USB charge pump pins		see <a href="#">Table 35–649</a>

### 2.2.2 Internal pins

[Table 30–607](#) shows the internal pin connections for data and control signals between the digital and analog die (see also [Table 30–605](#)).

**Table 607. Internal pin connections between the analog and digital die**

Analog die internal pin	connected to digital die internal pin	Description
I2SRX_DATA	I2STX_DATA1	I2S receive data pin. On the digital side this pin is connected to I2STX_DATA1.
I2STX_DATA	I2SRX_DATA1	I2S transmit data pin. On the digital side this pin is connected to I2SRX_DATA1.
TDI_I		JTAG pin
STD_I		JTAG pin
TRST_N_I		JTAG pin
TCK_I		JTAG pin
TMS_I		JTAG pin
I2C_SDA	I2C_SDA1	I2C control interface data pin. On the digital die side this pin is connected I2C_SDA1.
I2C_SCL	I2C_SCL1	I2C control interface clock pin. On the digital die side this pin is connected I2C_SCL1.
AD_NINT_O	GPIO20	This pin is asserted (driven low) when the RTC alarm interrupt is set. On the digital die side this pin is connected GPIO20.
PLAY_DET_O	GPIO19	This pin is asserted (driven high) when the analog die detects the PSU_PLAY button is pressed. On the digital die side this pin is connected GPIO19.

**Table 607. Internal pin connections between the analog and digital die**

Analog die internal pin	connected to digital die internal pin	Description
RSTIN_N_PSU_O	-	This pin is driven by the analog die to put the digital die under reset. Once power rails are stable, the analog die de-asserts this signal.
ADC10_GPA3_O	ADC10_GPA3	This pin is connected to the battery terminal pin inside the analog die. On the digital die side, this pin is connected to ADC10B_GPA3 so that software can do battery voltage measurements using channel 3 of 10bit ADC block.
GPIO_TST_0_AD to GPIO_TST_7_AD	GPIO11 to GPIO18	Unused GPIO pins. On the digital die side these pins are connected to GPIO11 to GPIO18.

### 3. Register overview

The analog die has its own register set which is accessed through the I<sup>2</sup>C1 interface. The analog block has one device slave address 0001100. All blocks in the analog die behave like one I<sup>2</sup>C slave device to the I<sup>2</sup>C1 interface.

Each analog die register combines functions for several blocks (etc. OTGDCLIC controls the PSU and the Li-ion charger). Therefore all analog die registers are described in this chapter. Details on the analog die functionality can be found in the following chapters describing the analog die blocks.

**Table 608. Analog die register addresses (device address 0x0C)**

Block	Register addresses
PSU/Li-ion charger	0x0000 - 0x000F
Audio Codec	0x0010 - 0x001F
RTC	0x0020 - 0x002F

**Table 609. Register overview for analog die**

Name	R/W	Register address	Description	Reset value
<b>PSU and Li-ion charger</b>				
OTGDCLIC	R/W	0x0000	PSU and Li-ion charger control register	
DCDCLIC	R	0x0001	PSU and Li-ion charger status register	
CGU_ANALOG	R/W	0x0002	Analog die CGU control register	
<b>Audio codec</b>				
AIN_0	R/W	0x0010	Analog input PGA control	
AIN_1	R/W	0x0011	Analog input control	
AOUT	R/W	0x0012	Analog output control	
DEC	R/W	0x0013	Decimator control	
INT_0	R/W	0x0014	Interpolator control	
INT_1	R/W	0x0015	Interpolator volume control	

**Table 609. Register overview for analog die**

Name	R/W	Register address	Description	Reset value
I2S1MUX	R/W	0x0016	I2S1 digital audio multiplexer control	
AOUTDECINT	R	0x0017	Analog out status	
<b>RTC</b>				
RTC_TIME	R/W	0x0020	RTC time shadow register	0x0000 0000
RTC_ALARM_TIME	R/W	0x0021	RTC alarm time register	0x4343 CE50
RTC_STATUS	R	0x0022	RTC status register	0x0001 2002
RTC_SET_ENA_STAT	W	0x0023	RTC set/enable register	-
RTC_CLR_ENA_STAT	W	0x0024	RTC clear register	-

### 3.1 Register access

The registers of the analog die are accessed by software using the I2C1 interface connected between the digital and analog die.

#### 3.1.1 Write cycle

[Table 30–610](#) shows the I<sup>2</sup>C-bus configuration for a write cycle. The write cycle is used to write the data to the internal registers. The device address is one byte, register address is two bytes long, and the data is always four bytes. Shaded cells in the table represent the actions from analog die and non-shaded cells represent actions from digital die.

1. The digital die begins by asserting a start condition (S).
2. The first byte (8 bits) contains the device address '0001100' and the R/W bit is set to logic 0 (WRITE).
3. The analog die asserts an acknowledgement (ACK).
4. The digital die writes the 16-bit address (ADDR) of the analog die register to which the data will be written. The 16 bit address is written with the Most Significant (MS) byte first followed by the Least Significant (LS) byte; after each byte the analog die asserts an acknowledgement (ACK).
5. The digital die sends four bytes of data with the Most Significant (MS) byte first and the Least Significant (LS) byte last; after each byte the analog die asserts an acknowledgement (ACK).
6. The analog die frees the I<sup>2</sup>C-bus allowing the digital die to generate a stop condition (P).

The format of the write cycle is as follows:

**Table 610. Master transmitter writes to analog die registers using the I2C1 interface**

START	Initial byte		Register address				Register data				STOP
	Device address	R/W	MS address byte	LS address byte	MS data byte	LS data byte	LS data byte	STOP			
S	0001100	0	ADDR bits 15:8	ADDR bits 7:0	DATA bits 31:24	DATA bits 23:16	DATA bits 15:8	DATA bits 7:0	P		
			ACK	ACK	ACK	ACK	ACK	ACK			

### 3.1.2 Read cycle

Table 30–611 shows the I2C-bus configuration for a read cycle. The read cycle is used to read the register data values from the analog die registers. Shaded cells in the table represent the actions from analog die and non-shaded cells represent actions from digital die.

1. The digital die begins by asserting a start condition (S).
2. The first byte (8 bits) contains the device address '0001100' and the R/W bit is set to logic 0 (WRITE).
3. The analog die asserts an acknowledgement (ACK).
4. The digital die writes the 16-bit address (ADDR) of the analog die register from which the data will be read. The 16 bit address is written, with the Most Significant (MS) byte first, followed by the Least Significant (LS) byte; after each byte the analog die asserts an acknowledgement (ACK).
5. The digital die generates a repeated start (Sr).
6. The digital die generates the device address '0001100' again, but this time the R/W bit is set to logic 1 (READ).
7. The analog die asserts an acknowledgement (ACK).
8. The analog die sends four bytes of data with the Most Significant (MS) byte first, and the Least Significant (LS) byte last; after each byte the digital die asserts an acknowledgement (ACK).
9. The analog die frees the I<sup>2</sup>C-bus allowing the digital die to generate a stop condition (P).

Table 611. Master transmitter reads from analog die registers using the I2C1 interface

START	Initial byte		Register address			Read address cycle			Register data				STOP		
	Device address	R/W	MS address byte	LS address byte	START	Device address	R/W	MS data byte	ACK	ACK	ACK	ACK		LS data byte	
S	0001100	0	ADDR bits 15:8	ADDR bits 7:0	ACK	Sr 0001100	1	DATA bits 31:24	ACK	DATA bits 23:16	ACK	DATA bits 15:8	ACK	DATA bits 7:0	P

## 4. Register description

### 4.1 Li-ion charger and PSU registers

#### 4.1.1 PSU and Li-ion charger control register OTGDCLIC

The OTGDCLIC is a R/W register and controls the PSU voltage regulators and the Li-ion charger. See [Section 32–2](#) and [Section 33–3](#).

Table 612. PSU and Li-ion charger control register (OTGDCLIC, address 0x0000)

Bit	Symbol	Description	Reset value
31:29	-	Reserved.	-
28	usbotg_ctrl	USBOTG charge pump control 0 = Charge pump is off. 1 = Charge pump is on.	0x0
27:25	-	Reserved.	
24	dcdc_ctrl_clk_stable	dcdc clock control 0 = dcdc will run on its internally generated clock. 1 = dcdc will run on SYSCLK connected to the digital die.	0x0
23	dcdc_ctrl_ldo_on	LDO on/off control 0 = Switch off LDO1 and LDO2. 1 = Switch on LDO1 and LDO2.	0x0
22:20	dcdc_ctrl_dc1c1_adjust	dcdc1 voltage setting (see <a href="#">Table 30–613</a> ).	0x3
19:17	dcdc_ctrl_dc1c2_adjust	dcdc2 voltage setting ( <a href="#">Table 30–614</a> ).	0x5
16	dcdc_ctrl_sel1v8	LDO3 settings 0 = LDO3 produces 1.4 V. 1 = LDO3 produces 1.8 V.	0x0
15:13	-	Reserved.	
12	lic_ctrl_charge_enable	Start charger 0 = charger off. 1 = charger enabled.	0x0
11:8	lic_ctrl_cs_bit[3:0]	Compensation setting. This field is programmed by boot ROM by reading the settings from polyfuses. The polyfuses are set during production based on silicon process corner of the analog die. Hence software when writing to this register should always read this field first and write back the value to this field for proper operation of Li-ion charge block.	varies from chip to chip
7:5	lic_ctrl_g_bit[2:0]	Chip temperature control loop gain setting 0 = lowest gain. 111 = highest gain.	0x7
4:2	lic_ctrl_tt_bit[2:0]	Chip temperature control loop threshold setting 0 = lowest temp: 65 C. 111 = highest temp: 125 C.	0x6
1	lic_ctrl_pontlim	Power for chip temperature control loop 0 = loop off. 1 = loop on.	0x1
0	lic_ctrl_pontbat	Enable CHARGE_VNTC pin temperature sensing for Li-ion battery (battery temperature control loop) 0 = sensing off. 1 = sensing on.	0x1

The DCDC\_CTRL\_DCDC1\_ADJUST register bits can be used to select the desired output voltage of dcdc1. [Table 30–613](#) shows the possible settings and the corresponding output voltage.

**Table 613. DCDC\_CTRL\_DCDC1\_ADJUST description**

DCDC_CTRL_DCDC1_ADJUST	Output voltage (V)
000	3.2
001	3.09
010	2.97
011	2.86
100	2.74
101	2.63
110	2.51
111	2.40

The DCDC\_CTRL\_DCDC2\_ADJUST register bits can be used to select the desired output voltage of dcdc2. [Table 30–614](#) shows the possible settings and the corresponding output voltage.

**Table 614. DCDC\_CTRL\_DCDC2\_ADJUST description**

DCDC_CTRL_DCDC2_ADJUST	Output voltage (V)
000	1.40
001	1.33
010	1.26
011	1.19
100	1.11
101	1.04
110	0.97
111	0.90

#### 4.1.2 PSU and Li-ion charger status register (DCDCLIC)

The DCDCLIC is a Read-only status register. See [Section 32–2](#) and [Section 33–3](#) for details.

**Table 615. PSU and Li-ion charger status register (DCDCLIC, address 0x0001)**

Bit	Symbol	Description	Reset value
31:25	-	Reserved	-
24	dcdc_ctrl_usb_detect	USB VBUS supply detect 0 = no 5 V USB bus detected. 1 = 5V USB bus detected.	-
23	dcdc_ctrl_invcont_1v2	dcdc2 mode status 1 0 = dcdc2 is running in continuous conduction mode. 1 = dcdc2 is not running in continuous conduction mode.	-
22	dcdc_ctrl_invcont_3v3	dcdc1 mode status 1 0 = dcdc1 is running in continuous conduction mode. 1 = dcdc1 is not running in continuous conduction mode.	-
21	dcdc_ctrl_invdisc_1v2	dcdc2 mode status 2 0 = dcdc2 is running in discontinuous conduction mode. 1 = dcdc2 is not running in discontinuous conduction mode.	-

**Table 615. PSU and Li-ion charger status register (DCDCLIC, address 0x0001) ...continued**

Bit	Symbol	Description	Reset value
20	dcdc_ctrl_invdisc_3v3	dcdc1 mode status 2 0 = dcdc1 is running in discontinuous conduction mode. 1 = dcdc1 is not running in discontinuous conduction mode.	-
19	dcdc_ctrl_invinit_1v2	dcdc2 mode status 3 0 = dcdc2 is running in initialization mode. 1 = dcdc2 is not running in initialization mode.	-
18	dcdc_ctrl_invinit_3v3	dcdc1 mode status 3 0 = dcdc1 is running in initialization mode. 1 = dcdc1 is not running in initialization mode.	-
17	dcdc_ctrl_invramp_1v2	dcdc2 mode status 4 0 = dcdc2 is running in ramp up mode. 1 = dcdc2 is not running in ramp up mode.	-
16	dcdc_ctrl_invramp_3v3	dcdc1 mode status 4 0 = dcdc1 is running in ramp up mode. 1 = dcdc1 is not running in ramp up mode.	-
15:7	-	Reserved	-
6	lic_ctrl_charger_on	charger on indicator 0 = charger is switched off or no correct supply condition. 1 = charger is switched on and correct supply condition.	-
5	lic_ctrl_battery_full	Battery full indicator 0 = battery empty. 1 = battery full.	-
4	lic_ctrl_trickle_charge	Trickle-charge indicator (10% current) 0 = charger not in trickle charge mode. 1 = charger is in trickle charge mode.	-
3	lic_ctrl_fast_charge	Fast-charge (or constant-current charge) indicator (100% current) 0 = charger not fast-charge mode. 1 = charger is in fast-charge mode.	-
2	lic_ctrl_cv_charge	Constant-voltage charge indicator 0 = charger not in constant-voltage charge mode. 1 = charger is in constant-voltage charge mode.	-
1	lic_ctrl_no_ntc	No NTC indicator 0 = temperature sense on. 1 = no NTC signal (when bit lic_ctrl_pontlim in OTGDCLIC is 0 (see <a href="#">Table 30-612</a> ), the chip temperature sense loop is powered down).	-
0	lic_ctrl_tempbat_ok	Battery temperature ok indicator 0 = temperature out of range. 1 = signal on pin CHARGE_VNTC between high and low thresholds (see <a href="#">Section 33-5.3</a> ).	-

#### 4.1.3 Analog die CGU control register (CGU\_ANALOG)

This register controls the clocks generated by the analog die CGU. The base clocks for the analog die, SYSCLK and CLK\_256FS, are generated by the CGU on the digital die (see [Table 13-195](#)).

See [Section 31-3.3.2](#) for details on how to select the analog input module ADC clocks.

Table 616. Analog die CGU register (CGU\_ANALOG, address 0x0002)

Bit	Symbol	Description	Reset value
31:24	-	Reserved	-
23	sel_clkdac_samephase	0 = clock phase DA inverted. 1 = clock phase DA not inverted.	0x0
22	cgu_ls_enable_off	0 = Level shifter RTC on. 1 = Level shifter RTC off.	0x0
21	sel_i2c_clk	select clock for the analog die I2C block. 0 = i2c block is clocked using SYSCLK. 1 = i2c block is clocked using CLK_256FS.	0x0
20	ain_sel_adcsys_256fs	select sampling clock for the SADC ain_clk_adcsys. See <a href="#">Section 31-3.3.2</a> . 0 = 128fs 1 = 256fs	0x0
19	ain_sel_adc1_off_1	0 = 128fs 1 = tied to '1'	0x0
18	ain_sel_adc2_128fs	0 = tied to '1' 1 = 128fs	0x0
17	aout_sel_clkdac_256fs	select DAC clock 0 = 128fs 1 = 256fs	0x0
16	int_sel_clkns_256fs	select clock int_clk_ns for interpolator 0 = 128fs 1 = 256fs	0x0
15	-	Reserved	-
14	pd_ain_clk_adcsys	Power-down for SADC clock ain_clk_adcsys 0 = ain_clk_adcsys is powered. 1 = ain_clk_adcsys is powered down.	0x1

## 4.2 Audio codec registers

### 4.2.1 Analog input PGA control register

This register is R/W and controls the gain setting of the PGA, see [Section 31–3.5.6](#).

**Table 617. Analog input PGA control register (AIN\_0, address 0x0010)**

Bit	Symbol	Description	Reset value
31:12	-	Reserved	-
11:8	ain_ctrl_pga1	Gain of PGA1 (left channel), see <a href="#">Table 30–618</a> .	0x0
7:4	ain_ctrl_pga2	Gain of PGA2 (microphone input), see <a href="#">Table 30–618</a> .	0x0
3:0	ain_ctrl_pga3	Gain of PGA3 (right channel), see <a href="#">Table 30–618</a> .	0x0

**Table 618. PGA gain settings in register AIN\_0**

Bit 3/7/11	Bit 2/6/10	Bit 1/5/9	Bit 0/4/8	Gain
0	0	0	0	0 dB
0	0	0	1	3 dB
0	0	1	0	6 dB
0	0	1	1	9 dB
0	1	0	0	12 dB
0	1	0	1	15 dB
0	1	1	0	18 dB
0	1	1	1	21 dB
1	x	x	x	24 dB

#### 4.2.2 Analog input control register (AIN\_1)

This register is R/W and inputs and power to the SDC, PGA, and ADC parts of the audio codec. See [Section 31–3.5](#).

**Table 619. Analog input control register (AIN\_1, address 0x0011)**

Bit	Symbol	Description	Reset value
31:19	-	Reserved	-
18:17	ain_ctrl_mux_l	MUX0 & MUX1 input selection for left channel 0 = Tuner input 1 = Line input 2 = Mic input tuner by-pass 3 = Mic input Line-in by-pass	0x1
16:15	ain_ctrl_mux_r	MUX0 & MUX1 input selection for right channel 0 = Tuner input 1 = Line input 2 = Mic input tuner by-pass 3 = Mic input Line-in by-pass	0x1
14	ain_ctrl_pd_lna1	LNA power down 0 = Normal operation 1 = Power down LNA1	0x1
13	ain_ctrl_pd_pga1	PGA1 (left channel) power down 0 = Normal operation 1 = Power down PGA1	0x1
12	ain_ctrl_pd_pga2	PGA2 (microphone input) power down 0 = Normal operation 1 = Power down PGA2	0x1
11	ain_ctrl_pd_pga3	PGA3 (right channel) power down 0 = Normal operation 1 = Power down PGA3	0x1
10	ain_ctrl_pd_sdc1	SDC1 (left channel) power down 0 = Normal operation 1 = Power down SDC1	0x1
9	ain_ctrl_pd_sdc2	SDC2 (microphone input) power down 0 = Normal operation 1 = Power down SDC2	0x1
8	ain_ctrl_pd_sdc3	SDC3 (right channel) power down 0 = Normal operation 1 = Power down SDC3	0x1
7	ain_ctrl_pd_adc1	ADC left power down 0 = Normal operation 1 = Power down ADC1	0x1
6	ain_ctrl_pd_adc2	ADC right power down 0 = Normal operation 1 = Power down ADC2	0x1
5	ain_ctrl_pd_bias1	BIAS1 power down 0 = Normal operation 1 = Power down BIAS1	0x1
4	ain_ctrl_pd_vcom_vref1	ADC_VREF power down 0 = Normal operation 1 = Power down ADC_VREF	0x1

**Table 619. Analog input control register (AIN\_1, address 0x0011) ...continued**

Bit	Symbol	Description	Reset value
3	ain_ctrl_dither1	ADC dither input (left channel) 0 = No dithering left channel 1 = Dithering left channel	0x1
2	ain_ctrl_dither2	ADC dither input (right channel) 0 = No dithering right channel 1 = Dithering right channel	0x1
1	ain_ctrl_xfbad1	ADC enable feedback in loopfilter (left channel) 0 = Poles at DC for audio applications 1 = Higher S/N for radio applications	0x0
0	ain_ctrl_xfbad2	ADC enable feedback in loopfilter (right channel) 0 = Poles at DC for audio applications 1 = Higher S/N for radio applications	0x0

### 4.2.3 Analog output control register AOUT

This register is R/W and controls the DAC and headphone amplifiers of the Audio codec output block. For details see [Section 31–4](#).

**Table 620. Analog output control register (AOUT, address 0x0012)**

Bit	Symbol	Description	Reset value
31	aout_ctrl_sw dac_on	Control the AVC switches of SDAC 0 = Only AVC outputs are connected to the class AB amplifier input. 1 = Both AVC and SDAC outputs are connected to the class AB amplifier input.	0x1
30	aout_ctrl_vref_slow_up	Control for slow reference voltage 0 = Slow reference voltage down 1 = Slow reference voltage up	0x0
29:16	aout_ctrl_gain_avc[13:0]	Gain of the Analog Volume Control (AVC) (see <a href="#">Section 31–4.4.2</a> )	0x0
15	aout_ctrl_pd_vref_slow	Power down the reference 0 = Normal operation 1 = Power down reference	0x1
14	aout_ctrl_pd_hp_l	Power down the left headphone amplifier 0 = Normal operation 1 = Power down left headphone amplifier	0x1
13	aout_ctrl_pd_hp_c	Power down the common ground headphone amplifier 0 = Normal operation 1 = Power down common ground headphone amplifier	0x1
12	aout_ctrl_pd_hp_r	Power down the right headphone amplifier 0 = Normal operation 1 = Power down right headphone amplifier	0x1

Table 620. Analog output control register (AOUT, address 0x0012) ...continued

Bit	Symbol	Description	Reset value
11:10	aout_ctrl_set_limiter_l[1:0]	Current limiter setting (short-circuit protection) left channel 0 = Max current: off 1 = Max current: 100 mA 2 = Max current: 120 mA 3 = Max current: 140 mA	0x1
9:8	aout_ctrl_set_limiter_c[1:0]	Current limiter setting (short-circuit protection) common ground channel 0 = Max current: off 1 = Max current: 200 mA 2 = Max current: 240 mA 3 = Max current: 280 mA	0x1
7:6	aout_ctrl_set_limiter_r[1:0]	Current limiter setting (short-circuit protection) right channel 0 = Max current: off 1 = Max current: 100 mA 2 = Max current: 120 mA 3 = Max current: 140 mA	0x1
5	aout_ctrl_pd_sdac_l	Power down the SDAC Left 0 = Normal operation 1 = Power down SDAC Left	0x1
4	aout_ctrl_pd_sdac_r	Power down the SDAC Right 0 = Normal operation 1 = Power down SDAC Right	0x1
3	aout_ctrl_pd_set_format	Input format of the I2S bus 0 = Input offset binary format 1 = Input two's complement format	0x1
2	aout_ctrl_pd_set_dwa	Data Weight Algorithm 0 = Uni-directional Data Weight Algorithm (best S/N performance) 1 = Bi-directional Data Weight Algorithm (best distortion performance)	0x0
1	aout_ctrl_pd_anvc_l	Power down the Analog Volume Control (AVC) Left 0 = Normal operation 1 = Power down AVC Left	0x1
0	aout_ctrl_pd_anvc_r	Power down the Analog Volume Control (AVC) Right 0 = Normal operation 1 = Power down AVC Right	0x1

#### 4.2.4 Decimator control register (DEC)

This register is R/W and controls the decimator block and the Automatic Gain Control (AGC) block of the Audio Codec (see also [Section 31–4.5](#)).

**Table 621. Decimator control register (DEC, address 0x0013)**

Bit	Symbol	Description	Reset value
31:28	-	Reserved	-
27:25	dec_ctrl_agctim[2:0]	AGC Time Constant (see <a href="#">Table 30–622</a> )	0x0
24:23	dec_ctrl_agclvl[1:0]	AGC Level 00 = AGC Target level -5.5 dBFS 01 = AGC Target level -8.0 dBFS 10 = AGC Target level -11.5 dBFS 11 = AGC Target level -14.0 dBFS	0x0
22	dec_ctrl_agcen	AGC Enable 0 = AGC off; manual gain control via the left/right decimator volume control 1 = Enable AGC; manual microphone gain settings via PGA	0x0
21	dec_ctrl_en_mute	Enable mute 0 = Normal operation 1 = Mute left and right channels	0x0
20	dec_ctrl_en_pol_inv	Enable polarity inversion 0 = Normal operation 1 = Polarity inversion left and right channels	0x0
19	dec_ctrl_en_dcfilti	Enable input DC blocking filter 0 = Disable input DC blocking filter 1 = Enable input DC blocking filter	0x0
18	dec_ctrl_en_dcfilto	Enable DC blocking filter after decimation filters 0 = Disable output DC blocking filter 1 = Enable output DC blocking filter	0x0
17	dec_ctrl_en_dblin	Enable soft start-up after a reset 0 = Disable db linear after reset 1 = Enable db linear after reset	0x0
16	dec_ctrl_en_delay_dblin	Enable delay timer after a reset 0 = Disable timer after reset 1 = Enable timer after reset	0x0
15:8	dec_ctrl_gain_l[7:0]	Gain settings, LEFT channel (2's compliment format 0.5dB/bit)	0x0
7:0	dec_ctrl_gain_r[7:0]	Gain settings RIGHT channel (2's compliment format 0.5dB/bit)	0x0

Bits dec\_ctrl\_agctim[2:0] are a 3-bit value to set the AGC time constants, which are the attack and decay time constants. The constants provided are for 44.1 kHz and 8 kHz sampling frequencies, and must be scaled down or up according to the sampling frequency used.

**Table 622. AGC time constant settings**

dec_ctrl_agctim[2]	dec_ctrl_agctim[1]	dec_ctrl_agctim[0]	AGC setting			
			44.1 kHz sampling		8 kHz sampling	
			Attack time (ms)	Decay time (ms)	Attack time (ms)	Decay time (ms)
0	0	0	11	100	61	551
0	0	1	16	100	88.2	551
0	1	0	11	200	61	1102
0	1	1	16	200	88.2	1102

Table 622. AGC time constant settings ...continued

dec_ctrl_agctim[2]	dec_ctrl_agctim[1]	dec_ctrl_agctim[0]	AGC setting			
			44.1 kHz sampling		8 kHz sampling	
			Attack time (ms)	Decay time (ms)	Attack time (ms)	Decay time (ms)
1	0	0	21	200	116	1102
1	0	1	11	400	61	2205
1	1	0	16	400	88.2	2205
1	1	1	21	400	116	2205

#### 4.2.5 Interpolator control register INT0

This register is R/W and control the interpolator block of the Audio Codec. See also [Section 31–4](#).

Table 623. Interpolator control register (INT0, address 0x0014)

Bit	Symbol	Description	Reset value
31:16	-	Reserved	-
15	int_ctrl_en_pol_inv	Enable polarity inversion 0 = Polarity inversion disabled 1 = Polarity inversion enabled	0x0
14:13	int_ctrl_set_filter[1:0]	filter coefficient settings for sharp/slow roll-off 00 = 2fs to 8fs FIR filter coefficients for slow roll-off 01 = 2fs to 8fs FIR filter coefficients for slow roll-off 10 = 2fs to 8fs FIR filter coefficients for slow roll-off 11 = 2fs to 8fs FIR filter coefficients for sharp roll-off	0x0
12:11	int_ctrl_set_speed_mode[1:0]	input data rate settings (1fs or 8 fs) 00 = 1fs (normal) speed mode 01 = 2fs (double) speed mode 10 = 2fs (double) speed mode 11 = 8fs speed mode	0x0
10:9	int_ctrl_set_ns[1:0]	noise shaper settings (1-bit, 4-bit, 5-bit or 6-bit) 00 = 1-bit noise shaped output data format 01 = 4-bit noise shaped output data format 10 = 5-bit noise shaped output data format 11 = 6-bit noise shaped output data format	0x1
8	int_ctrl_set_pd_slope	DC ramp up/down slope setting 0 = power down/up slope: 65536 × DSP clock cycles (11.6 ms @ 128fs = 44.1 kHz) 1 = power down/up slope: 131072 × DSP clock cycles (23.2 ms @ 128fs = 44.1 kHz)	0x0
7	int_ctrl_pd_dac	Enable power down sequence interpolator 0 = power down sequence disabled i.e. DC ramp up followed by raised cosine amplification 1 = power down sequence enabled i.e. raised cosine attenuation followed by DC ramp down	0x0
6	int_ctrl_en_sd	Silence detection enable 0 = Silence Detection disabled 1 = Silence Detection enabled	0x0

**Table 623. Interpolator control register (INT0, address 0x0014) ...continued**

Bit	Symbol	Description	Reset value
5:4	int_ctrl_set_sd_value[1:0]	silence detection time window 0 = set_sd_value; 3200 fs samples 1 = set_sd_value; 4800 fs samples 2 = set_sd_value; 9600 fs samples 3 = set_sd_value; 19200 fs samples	0x0
3	int_ctrl_set_silence	overruling silence switch input 0 = normal operation 1 = overrule sd_l and sd_r output pins	0x0
2:0	int_ctrl_deem_channel1[2:0]	Set de-emphasis channel 1. (Note Channel 2 is not used) 000 = no digital de-emphasis 001 = digital de-emphasis for fs = 32 kHz 010 = digital de-emphasis for fs = 44.1 kHz 011 = digital de-emphasis for fs = 48 kHz 100 = digital de-emphasis for fs = 96 kHz 101 = no digital de-emphasis	0x0

#### 4.2.6 Interpolator volume control register INT1

This register is R/W and contains the analog output volume control.

**Table 624. Interpolator volume control register (INT1, address 0x0015)**

Bit	Symbol	Description	Reset value
31:17	-	Reserved	-
16	int_ctrl_mute	Mute interpolator	0x0
15:8	int_ctrl_mastervol_r[7:0]	Set volume right channel	0x0
7:0	int_ctrl_mastervol_l[7:0]	Set volume left channel	0x0

#### 4.3 I2S1 digital audio multiplexer control register I2S1MUX

This register is R/W and controls the I2S interface between the audio codec on the analog die and the I2S1 interface on the digital die.

**Table 625. I2S1 digital audio multiplexer control register (I2SMUX, address 0x0016)**

Bit	Symbol	Description	Reset value
31:17	-	Reserved	-
16	dmux_ctrl_bypass	Selection for Digital Mux 0 = I2SRX interface is connected to interpolator 1 = Decimator is connected to Interpolator	0x1
15:11	-	Reserved	-

**Table 625. I2S1 digital audio multiplexer control register (I2SMUX, address 0x0016)**

Bit	Symbol	Description	Reset value
10:8	I2SRX_ctrl_set[2:0]	Serial interface mode I2SRX interface 000 = DAD/ISN/LIRS 001 = SPD3 format 010 = Reserved 011 = NXP I2S 100 = LSB justified 16 bits 101 = LSB justified 18 bits 110 = LSB justified 20 bits 111 = LSB justified 24 bits	011
7:3	-	Reserved	-
2:0	I2STX_ctrl_set[2:0]	Serial interface mode I2STX interface 000 = Reserved 001 = Reserved 010 = Reserved 011 = NXP I2S 100 = LSB justified 16 bits 101 = LSB justified 18 bits 110 = LSB justified 20 bits 111 = LSB justified 24 bits	011

#### 4.4 Analog out status register (AOUTDECINT)

This register is a R only and provides the status of the analog output block (see [Section 31–4](#)).

**Table 626. Analog out status register (AOUTDECINT, address 0x0017)**

Bit	Symbol	Description	Reset value
31:27	-	Reserved	-
26	aout_ctrl_clip_l	Output of left headphone amplifier is clipped 0 = Normal operation 1 = Output of left headphone amplifier is clipped	-
25	aout_ctrl_clip_c	Output of common ground headphone amplifier is clipped 0 = Normal operation 1 = Output of common ground headphone amplifier is clipped	-
24	aout_ctrl_clip_r	Output of right headphone amplifier is clipped 0 = Normal operation 1 = Output of right headphone amplifier is clipped	-
23:19	-	Reserved	-
18	dec_ctrl_agc_stat	T.B.F.	-
17	dec_ctrl_mute_state	Output muted status indicator 0 = No mute or mute/de-mute in progress 1 = Left and right channels muted"	-

**Table 626. Analog out status register (AOUTDECINT, address 0x0017) ...continued**

Bit	Symbol	Description	Reset value
16	dec_ctrl_overflow	Overflow indicator 0 = No overflow 1 = Overflow in left or right channel	-
15	-	Reserved	-
14	int_ctrl_pd_ready	Power down sequence completed; actual power down signal for DAC 0 = no power down or power down in progress 1 = left and right channels powered down	-
13	int_ctrl_ds_l	DAC silence switch control signal LEFT 0 = no silence detected 1 = silence detected in channel 1 & 2	-
12	int_ctrl_ds_r	DAC silence switch control signal RIGHT 0 = no silence detected 1 = silence detected in channel 1 & 2	-
11	int_ctrl_inv_n_dac	control signal to invert neg. channel data for differential application 0 = No inversion 1 = Negative channel data is inverted for differential application"	-
10	int_ctrl_mute_state_m	mute status of master channel 0 = no mute or mute/de-mute in progress 1 = left and right channels muted	-
9	int_ctrl_sdetected_l1	silence detection output channel 1 LEFT 0 = no silence detected LEFT channel 1 = silence detected LEFT channel	-
8	int_ctrl_sdetected_r1	silence detection output channel 1 RIGHT 0 = no silence detected RIGHT channel 1 = silence detected RIGHT channel	-
7:1	int_ctrl_dacpc[6:0]	program counter that runs from 0 to 127 on the clk_in_dsp clock for the interpolator	-
0	int_ctrl_fs_pulse	one interpolator DSP clock cycle pulse at 1fs frequency	-

## 4.5 RTC registers

### 4.5.1 RTC time shadow register (RTC\_TIME)

This register is R/W and is updated every second with the time elapsed since epoch. The reference date is the standard epoch of January 1st, 1970.

The time grid is based on the 32 kHz clock. Writing to the RTC\_TIME register can therefore have an inaccuracy of up to 30.5 ms.

**Table 627. RTC time shadow register (RTC\_TIME, address 0x0020)**

Bit	Symbol	Description	Reset value
31:0	TIME	Time in seconds since epoch.	0x00

### 4.5.2 RTC alarm register (RTC\_ALARM)

This register is R/W and contains the alarm time in seconds after epoch (Jan 1st, 1970). The alarm will cause an interrupt one second after being equal to the time register RTC\_TIME.

**Table 628. RTC alarm register (RTC\_ALARM, address 0x0021)**

Bit	Symbol	Description	Reset value
31:0	ALARM_TIME	Alarm time setting. The alarm interrupt will be set 1 sec after a match with the RTC_TIME register.	0x4343 CE50

[1] The reset value is 05 October 2005, 13:00 hrs, based on seconds since standard Epoch of 01 January 1970.

### 4.5.3 RTC status register (RTC\_STATUS)

This register is R only and contains the status bits of the RTC.

**Table 629. RTC status register (RTC\_STATUS, address 0x0022)**

Bit	Symbol	Description	Reset value
31:17	-	Reserved. read as 0.	-
16	TIME_PENDING	1 = Time in RTC_TIME shadow register has not yet been updated from the RTC time counter. 0 = Time has been updated.	0x1
15:14	-	Reserved	-
13	LS_ENA	1 = Software access (via level shifters) is enabled. 0 = Software access to RTC registers other than RTC_STATUS not allowed.	0x1
12	RST_RTC	1= The RTC is in reset. Only occurs when power is initially applied to the RTC power domain. 0= Software access allowed.	0x0
11:10	-	Reserved. Read as 0.	-
9	RTC_INT_ENA	1 = Alarm assertion to the RTC_INT pin is disabled. On board it is recommended to connect RTC_INT pin to PSU_PLAY button to wake the chip using alarm event. 0 = Alarm interrupt will assert the RTC_INT pin.	0x0
8	AD_INT_ENA	1 = Alarm to the event router is disabled. 0 = Alarm is enabled to generate an interrupt at the event router.	0x0
7:2	Reserved	Reserved. Read as 0.	-
1	TIME_UNSET	1 = Time undefined. Time was never set or was lost due to power lost. 0 = Time valid.	0x1
0	ALARM	1 = RTC time counter has matched the Alarm time. 0 = Alarm match has not happened.	0x0

### 4.5.4 RTC set enable and status register (RTC\_SET\_ENA\_STAT)

This register is W only and is used to enable the alarm function on the RTC. Writing a 1 to any bit in the register will also set the corresponding status register (RTC\_STATUS, [Table 30–629](#)). There is no need to write back 0x0.

**Table 630. RTC set enable and status register (RTC\_SET\_ENA\_STAT, address 0x0023)**

Bit	Symbol	Description	Reset value
31:10	-	Reserved	-
9	RTC_INT_ENA_SET	Write 1 to enable the alarm via the RTC_INT pin. On board it is recommended to connect pin RTC_INT to pin PSU_PLAY to wake up the chip using an alarm event. <a href="#">[1]</a> .	-
8	AD_INT_ENA_SET	Write 1 to enable the alarm to the event router <a href="#">[1]</a> .	-
7:2	-	Reserved.	-
1	TIME_UNSET_SET	Write 1 to set the status 'time undefined' <a href="#">[1]</a> .	-
0	ALARM_SET	Write 1 to set the alarm status.	-

[1] Writing 0 to this bit has no effect. Writing 1 will set the corresponding status register.

#### 4.5.5 RTC clear enable status register (RTC\_CLR\_ENA\_STAT)

This register is W only and is used to clear the alarm function. Writing a 1 to any bit in this register will also clear the corresponding bit in the RTC\_STAT register. There is no need to write back 0x0.

**Table 631. RTC Clear enable and status registers (RTC\_CLR\_ENA\_STAT, address 0x0024)**

Bit	Symbol	Description	Reset Value
31:10	-	Reserved.	-
9	RTC_INT_ENA_CLR	Write 1 to disable the alarm via the RTC_INT pin. On board it is recommended to connect pin RTC_INT to pin PSU_PLAY to wake up the chip using an alarm event. <a href="#">[1]</a> .	-
8	AD_INT_ENA_CLR	Write 1 to disable the alarm to the event router <a href="#">[1]</a> .	-
7:2	-	Reserved.	-
1	TIME_UNSET_CLR	Write 1 to clear the status 'time undefined' <a href="#">[1]</a> .	-
0	ALARM_CLR	Write 1 to clear the alarm status <a href="#">[1]</a> .	-

[1] Writing zero to this bit has no effect. Writing '1' will clear the corresponding status register.

## 1. Introduction

---

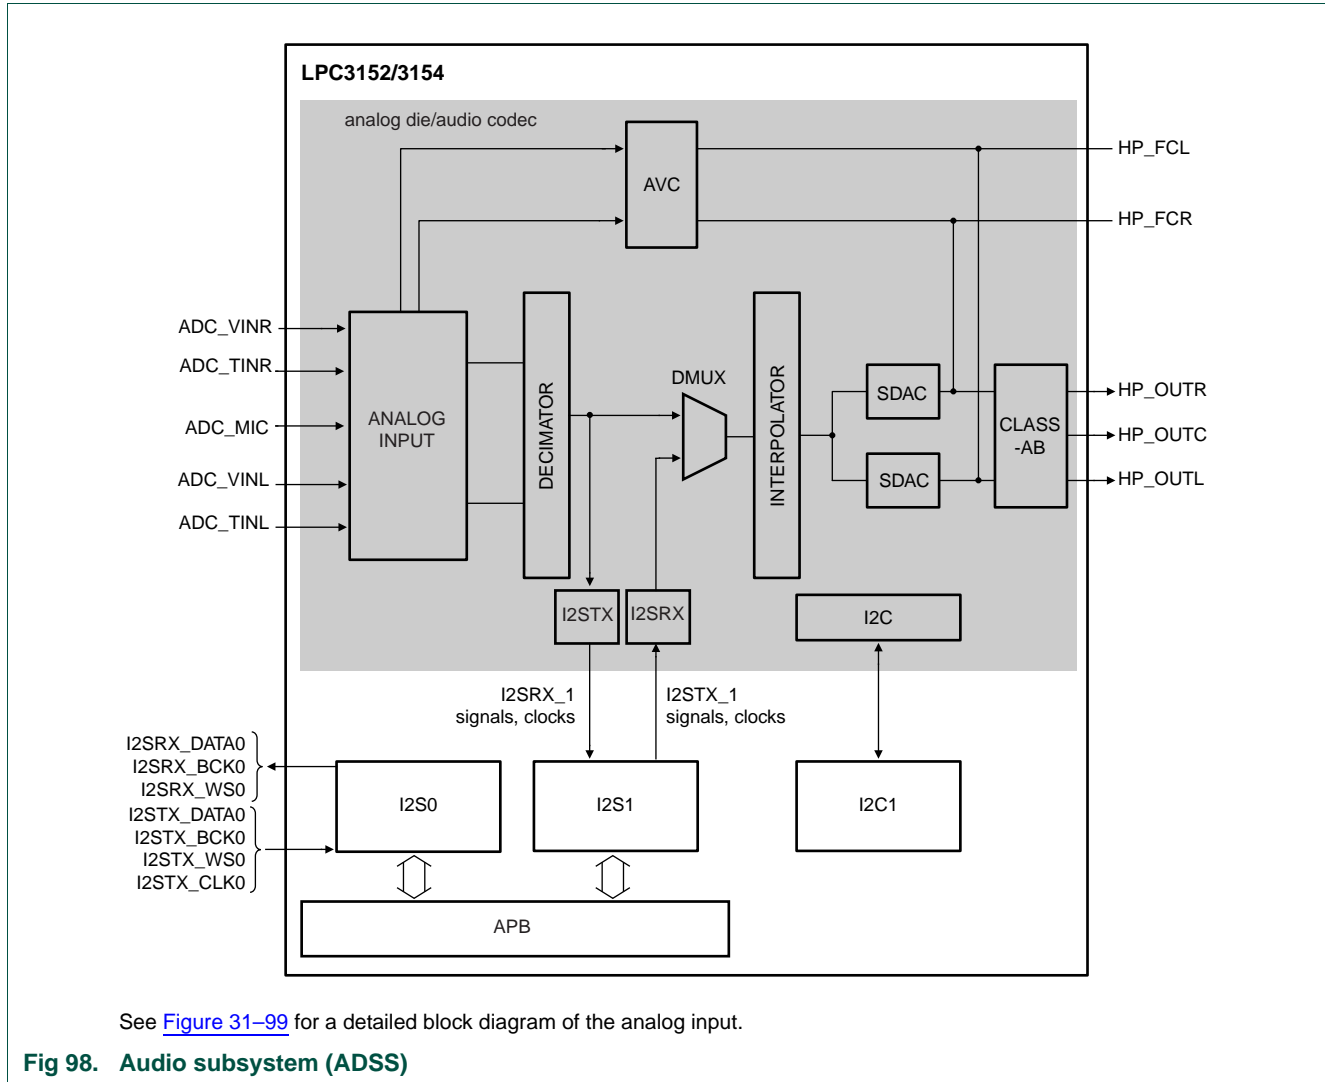

The Audio Subsystem (ADSS), consists of two parts: The digital die and the analog die.

The digital die part contains of the I2S0/1 interfaces and is described in [Section 29–1](#).

The analog die part contains the audio codec and has an analog input and an analog output (with Class AB amplifier). For improved audio quality, a decimator and an interpolator module are added. For I2S communication with the digital die's I2S1 interface, the analog die contains an I2SRX and an I2STX module. The analog die registers are controlled through the I2C1 interface.

## 2. General description

### 2.1 Block diagram

See [Figure 31-99](#) for a detailed block diagram of the analog input.

Fig 98. Audio subsystem (ADSS)

## 3. Analog input

### 3.1 Introduction

The Stereo Analog-to-Digital Converter (SADC) can convert analog audio input signals into digital audio signals as shown in [Figure 31-99](#). The module has three input signals: stereo line-in, stereo tuner-in, and mono microphone in. These signals can be pre-processed by a Low Noise Amplifier (LNA, microphone input only), a Programmable Gain Amplifier (PGA) and a Single-to-Differential Converter (SDC) before they arrive at the input of the actual SADC.

### 3.1.1 Features

- Three input options: line-in (stereo), tuner-in (stereo), microphone-in (mono).
- Low Noise Amplifier (LNA) with a fixed 30 dB gain for the microphone input.
- Programmable Gain Amplifier (PGA), gain can be set in steps of 3 dB up to 24 dB.
- Single-to-differential converter (SDC).
- Stereo Analog-to-Digital converter (switched cap).
- Supported audio sample frequencies 8 kHz to 55 kHz.
- Over-sampling rate 128 times the sample frequency.
- High dynamic range.
- Digital dB-linear volume control in 0.5 dB steps.
- DC blocking filter (optional).
- Soft start-up.
- Mute detection/overflow detection.

## 3.2 General description

### 3.2.1 Block diagram

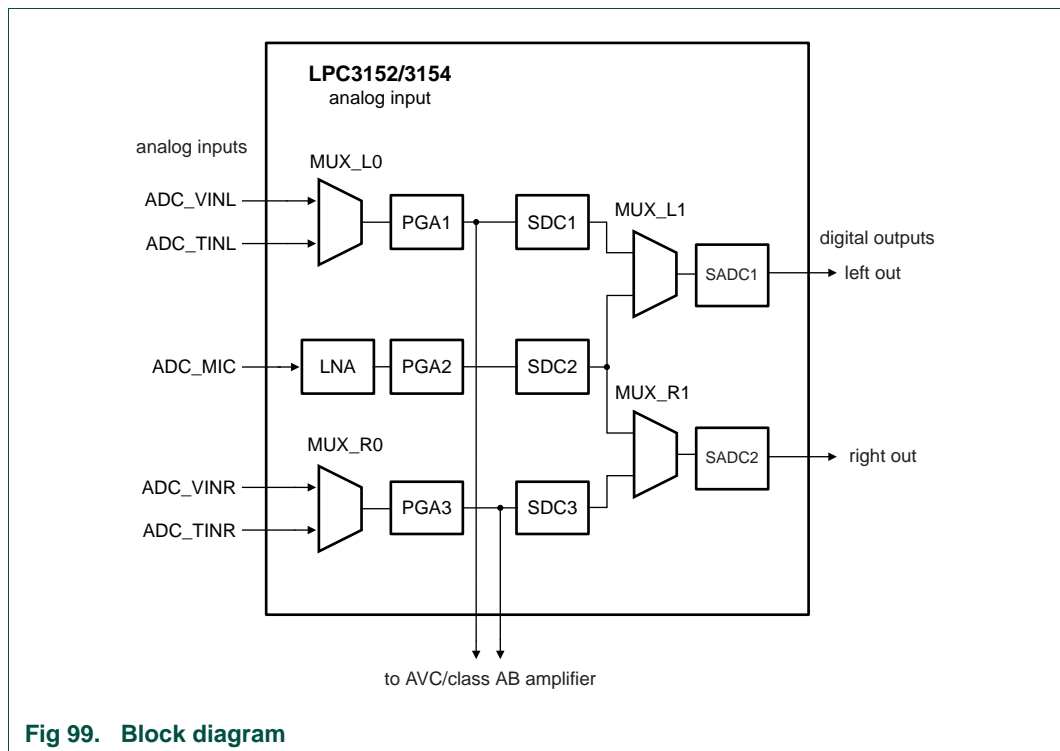

Fig 99. Block diagram

### 3.3 Interface description

#### 3.3.1 Clock signals

**Table 632. Clock signals of the analog input block**

Clock name	I/O	Source/destination	Description
ain_adc_clkad1	I	analog die CGU	Clock input 1 ADC. This clock is only used for ADC.
ain_adc_clkad2	I	analog die CGU	Clock input 2 ADC. This clock is only used for ADC.
ain_adc_clksys	I	analog die CGU	System clock ADC. This clock is only used for ADC.

#### 3.3.2 ADC clocking

The Analog input module requires a  $128 \times f_s$  clock, where  $f_s$  can be from 8 kHz to 55 kHz depending on the application. For audio applications  $f_s$  is typically 44.1 kHz and for radio applications  $f_s$  is 38 kHz.

The ADC performs a sampling on both edges of the internal clock (internal clkad). To minimize the sampling of digitally induced noise, the ADC clock must change states at a moment of little digital activity. This is achieved by doing the actual sampling within the ADC approximately 15 ns after the internal clkad changes its state.

The clocking of the ADC is made as flexible as possible. The ADC can be used with or without a system clock `ain_clk_adcsys`.

The system clock must be at least twice and an integer multiple of the ADC clock input,  $128 \times f_s$ , connected to `ain_clk_adc2`. The other clock signal `ain_clk_adc1` must be tied high.

If there is no higher system clock available, the ADC must be clocked with the  $128 \times f_s$  clock directly. This clock is fed to both `ain_clk_adcsys` and `ain_clk_adc1`. The other clock signal `ain_clk_adc2` must be tied high.

#### 3.3.3 Pin connections

**Table 633. Analog input pin connections**

Name	Type	Reset	Description
ADC_TINL	I	-	Left tuner input
ADC_TINR	I	-	Right tuner input
ADC_MIC	I	-	Microphone input
ADC_VINL	I	-	Left line input
ADC_VINR	I	-	Right line input
ADC_VREF	AO	-	ADC Reference Voltage output
ADC_VREFN	AI	-	ADC Negative Reference Voltage
ADC_VREFP	AI	-	ADC Positive Reference Voltage
ADC_VDDA18	Supply	-	ADC Digital Voltage supply
ADC_VDDA33	Supply	-	ADC Analog Voltage supply
ADC_GNDA	Ground	-	ADC Analog ground

### 3.4 Register overview

The analog input registers are described in detail in [Section 30–4.2](#).

Table 634. Register overview for the analog input

Name	R/W	Register address	Description
CGU_ANALOG	R/W	0x0002	see <a href="#">Table 30–616</a>
AIN_0	R/W	0x0010	see <a href="#">Table 30–617</a>
AIN_1	R/W	0x0011	see <a href="#">Table 30–619</a>

### 3.5 Functional description

#### 3.5.1 ADC analog front-end

The analog front-end of the ADC consists of one stereo ADC with a selector in front of it. Using this selector one can select the microphone input with the microphone amplifier (LNA) with a fixed 30 dB gain, the tuner input for FM radio signal or the line input. The microphone input as well as tuner and line inputs have a Programmable Gain Amplifier (PGA) that allows gain control from 0 dB to 24 dB in steps of 3 dB. The output of PGA is fed to a Single-to-Differential Converter (SDC) and then fed to the ADC. The output of ADC is a bitstream at  $128 \times f_s$ , which is the frequency set by `adc_sysclk`.

**Remark:** The input impedance of the PGA (line input) is 12 kOhm, for the LNA (mic input) this is 5 kOhm.

#### 3.5.2 Functional and Power-down modes

The following Power-down modes and/ or functional modes are supported:

- Power down mode in which the current consumption is very low (leakage currents only).  
**Remark:** In this mode there is no reference voltage at the line input.
- Mixed PGA and LNA mode (one line-in or tuner and one microphone input).
- Line in mode in which the PGA, SDC and ADC can be used.
- Tuner mode in which the PGA, SDC and ADC can be used.
- Microphone mode in which the rest of the non-used PGAs and SDCs are powered down.

**Remark:** In this mode the mono microphone signal can be sent to both left and right input of the ADC. At the same time, the line input or the tuner input can be by-passed to the AVC module. This is done with two separate MUX in front of the PGA and ADC individually. This MUX is controlled by the `ain_ctrl_mux[1:0]` bit in the AIN\_1 register (see [Table 30–619](#)).

#### 3.5.3 Stereo Analog to Digital Converter (SADC)

The SADC is a third order Sigma Delta Modulator (SDM). The loopfilter is a modified Ritchie-coder architecture in a differential switched capacitor implementation. The oversample ratio (OSR) is 128. The ADC has two modes of operation. First, it can be used with all three loopfilter poles at DC for audio applications. Second, it can be used with one pole at DC and two at a frequency of  $0.76 \times f_s$  for radio applications. For audio applications the ADC has a 98 dBA dynamic range in 20 kHz bandwidth and a typical sample frequency  $f_s$  of 44.1 kHz. For radio applications the ADC has a 87 dB dynamic range in 38 kHz bandwidth and a typical sample frequency  $f_s$  of 38 kHz. To achieve this dynamic range in the band of 38 kHz two of the three poles of the loopfilter are moved away from DC into the band of interest. The two poles are positioned at a complex

frequency of  $0.76 \times f_s$  (29 kHz). This increases the dynamic range from 81 dB to approximately 87 dB. The 38 kHz bandwidth makes it possible to digitize the FM demodulated signal directly and do the stereo decoding in the digital domain.

#### 3.5.4 Single-to-Differential Converter (SDC)

The Single-to-Differential Converter (SDC) consists of an inverting amplifier and a filter network. This filter is required for a switched-cap A/D Converter used in the LPC3152/54.

The input of the SDC is dc-coupled, which means that de-coupling must be done in front of this module in case the input signal has a different common mode level than the SDC. For optional biasing conditions, the SDC requires a sourcing bias current (into an NMOS transistor) that is preferably proportional to the analog supply voltage.

#### 3.5.5 Bias block

The bias block contains a bias circuit used for generating two reference voltages and up to 15 sourcing bias currents (sourced by PMOS transistors) of 10  $\mu$ A each.

The bias circuit contains two voltage dividers delivering two reference voltages that are half the supply voltage. Two reference voltages are needed since in the application with the delta-sigma Analog-to-Digital Converter, the input sampler is sinking and sourcing signal dependent currents for which the vref pin is designated. The vcom pin however can be used for all reference voltage that do not draw signal dependant currents such as the reference pin of the Single-to-Differential Converter.

#### 3.5.6 Programmable Gain Amplifier (PGA)

The input signal is amplified with a gain set by four control bits ctrl3 .. ctrl0 in the AIN\_0 register (see [Table 30–617](#)). The resulting signal will be available at vout. The control bit ctrl3 = '1' sets the gain to 24 dB independent of the other ctrl bits. Ctrl3 = '0' allows for other (lower) gain settings. The PGA is based on an inverting amplifier architecture. The feedback resistance exists of a resistor string. By switching between different resistors with the use of a 4-bit digital decoder, the gain of the amplifier can be modified. The gain can be set in steps of 3 dB up to 24 dB. The PGA is designed to handle a nominal 1.0 Vrms input level. A systematic gain of -1.94 dB ( $20 \times \log(0.8)$ ) is added to accommodate the 800 mVrms input level of a Single-to-Differential converter that is normally connected to the PGA output. The power-down signal is controlled by the digital core of the system chip.

CTRL3	CTRL2	CTRL1	CTRL0	GAIN
0	0	0	0	0 dB
0	0	0	1	3 dB
0	0	1	0	6 dB
0	0	1	1	9 dB
0	1	0	0	12 dB
0	1	0	1	15 dB
0	1	1	0	18 dB
0	1	1	1	21 dB
1	X	X	X	24 dB

Fig 100. PGA Gain settings

### 3.5.7 Applications with higher voltage input

For the line-in it is preferable to have 0dB and 6dB gain setting in order to be able to apply both 0.78 V (RMS) and 1.56 V (RMS) (using series resistance). For this purpose a PGA is used which has 0dB to 24dB gain with 3dB steps.

In applications in which a 1.56 V (RMS) input signal is used, a 12 kOhm resistor must be used in series with the input of the ADC. This forms a voltage divider together with the internal PGA resistor and ensures that only 0.78 V (RMS) maximum is input to the IC. Using this application for a 1.56 V (RMS) input signal, the switch must be set to 0 dB. When a 0.78 V (RMS) input signal is input to the ADC in the same application, the gain switch must be set to 6 dB.

An overview of the maximum input voltages allowed against the presence of an external resistor and the setting of the gain switch is given in [Table 31–635](#); the power supply voltage is assumed to be 3 V.

Fig 101. Schematic of ADC front-end with PGA

**Table 635. Application modes using input gain stage**

Resistor (12 kΩ)	Input Gain Switch	Maximum Input Voltage
Present	0 dB	1.56 V (rms)
Present	6 dB	0.78 V (rms)
Absent	0 dB	0.78 V (rms)
Absent	6 dB	0.39 V (rms)

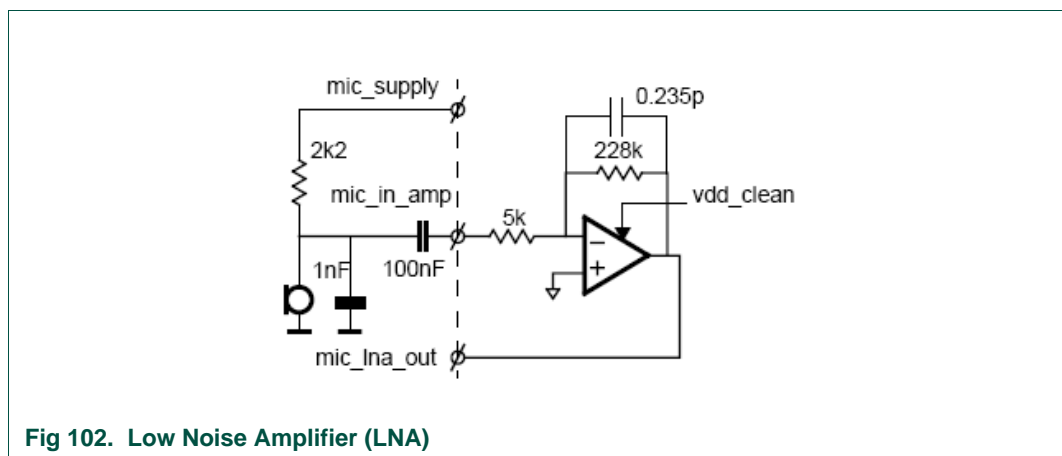

### 3.5.8 Low Noise Amplifier (LNA)

The gain of the Low Noise Amplifier (LNA) is determined by a combination of external and internal resistors. The nominal gain is 30 dB. Since internal and external resistors are un-correlated, the gain will depend somewhat on the IC process spread.

A microphone (type no. WM-54BH) delivers a nominal output voltage of -42 dBV at a sound pressure level of 1 Pa, which equals 94 dB-SPL. An average speaker at a distance of 0.5 m from the microphone produces a sound pressure level of about 70 dB-SPL. This will result in a nominal input voltage of about 0.5 mV (RMS) for the LNA. A very strong signal (105 dB-SPL) on the other hand will produce a microphone signal of about 30 mV (RMS) .

Given the specified SNR for the microphone of 60 dB at 1 Pa, the nominal microphone noise voltage will be about 8 μV (RMS). For the amplifier a low noise OpAmp with a high PSRR is used to keep the microphone noise the dominant factor in the overall performance of the circuit.

The nominal LNA equivalent input noise is 1.6 μV (RMS) . In combination with the microphone supply noise (3.3 μV (RMS)) this results in an equivalent input noise level of 3.7 μV (RMS). In combination with the microphone noise itself this results in a total noise level of 8.8 μV (RMS), which is just 1 dB above the noise of the microphone itself. The LNA gain of 30 dB is large enough to make the VGA input noise insignificant and at the same time low enough to prevent the LNA output from clipping at very strong input signals.

**Fig 102. Low Noise Amplifier (LNA)**

### 3.5.9 MUX

Several MUXs are used in the analog input block. They are used to select one of the inputs to the output. The selection is controlled by the AIN\_1 bit `ain_ctrl_mux` (see [Table 30–619](#)).

### 3.6 Power optimization

Each block used in the Analog input module has a power-down control input controlled by the AIN\_1 register (see [Table 30–619](#)). Always put blocks that are not in use in power-down mode.

## 4. Analog output

### 4.1 General description

This analog output block contains the Class AB headphone amplifier output. It has two inputs: an analog input, incorporating also an analog volume control, and a digital input. The analog signal is originating from the analog input module, the digital signal is originating from an interpolator, which is fed with the digital data stream coming from the I2S interface. [Figure 31–103](#) shows the two audio paths in a schematic way.

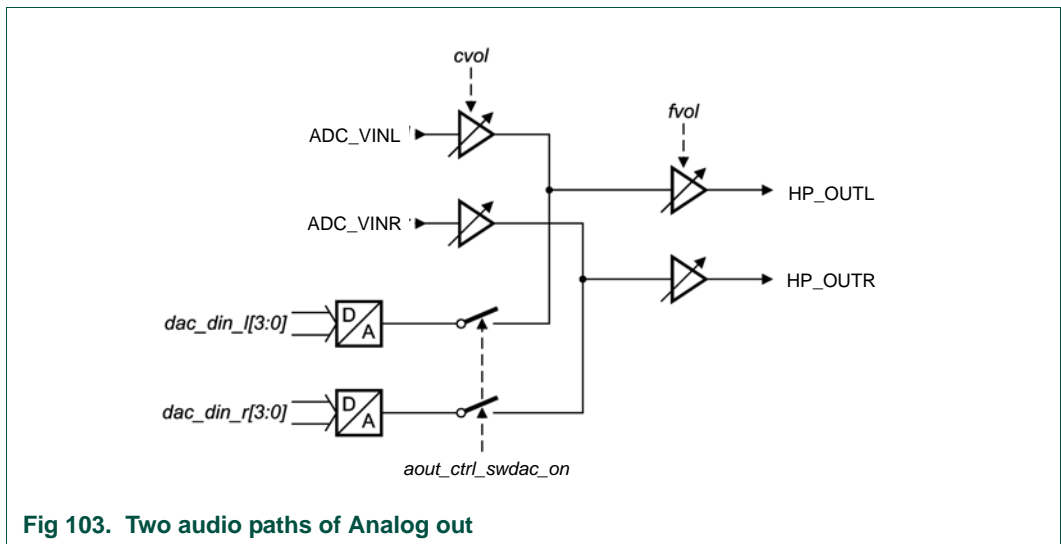

Fig 103. Two audio paths of Analog out

Analog out also contains circuits to generate the reference voltages needed for all its blocks. These circuits also provide functionality to slowly power up and power down the system in order to avoid audible plops. [Figure 31–104](#) shows the reference circuits in a schematic way.

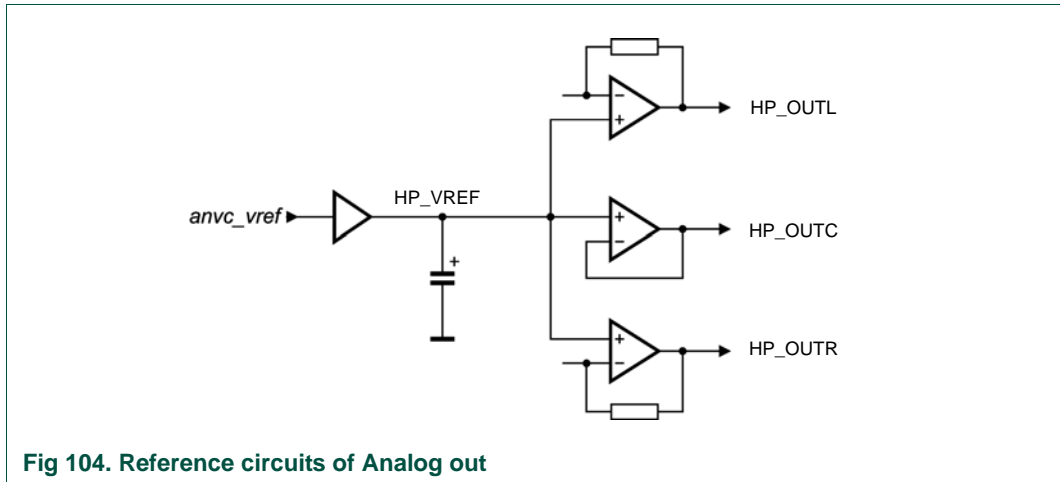

Fig 104. Reference circuits of Analog out

## 4.2 Pin connections

Table 636. Analog output pin connections

Pin	Type	Reset	Description
HP_OUTR	O	-	Headphone right output
HP_OUTC	O	-	Headphone common output reference Class AB
HP_OUTL	O	-	Headphone left output
HP_VREF	I	-	Analog reference supply for headphone and DAC
HP_FCL	I	-	Headphone filter capacitor left
HP_FCR	I	-	Headphone filter capacitor right
HP_VDDA33	Supply	-	Headphone Analog supply Class AB
HP_GNDA	Ground	-	Headphone Analog ground
DAC_VDDA33	Supply	-	SDAC Analog supply
DAC_VREFP	AI	-	SDAC Positive Reference Voltage
DAC_VREFN	AI	-	SDAC Negative Reference Voltage

## 4.3 Register overview

Table 637. Register overview for the analog output

Name	R/W	I2C address	Description
AOUT	R/W	0x0012	see <a href="#">Table 30–620</a>
DEC		0x0013	see <a href="#">Table 30–621</a>
INT_0		0x0014	see <a href="#">Table 30–623</a>
INT_1		0x0015	see <a href="#">Table 30–623</a>
I2SMUX		0x0016	see <a href="#">Table 30–625</a>
AOUTDECINT		0x0017	see <a href="#">Table 30–626</a>

## 4.4 Analog audio path

The following sections describe all the necessary steps to use the analog audio path. The two audio paths can be used at the same time, but normally the digital audio path must be powered down ([Table 30–620](#): aout\_ctrl\_pd\_sdac\_l = 1; aout\_ctrl\_pd\_sdac\_r = 1;

pd\_aout\_clk\_dac = 1) and muted ([Table 30–623](#): int\_ctrl\_mute = 1) before starting. Also the switches must be open then (aout\_ctrl\_sw\_dac\_on = 0). For all bits that are mentioned below, the default state is assumed as starting point.

#### 4.4.1 Power-up sequence

First the volume control block and the headphone amplifier can be turned on ([Table 30–620](#): aout\_ctrl\_pd\_anvc\_l = 0; aout\_ctrl\_pd\_anvc\_r = 0; aout\_ctrl\_pd\_hp\_l = 0; aout\_ctrl\_pd\_hp\_c = 0; aout\_ctrl\_pd\_hp\_r = 0). Then the reference buffer must be turned on ([Table 30–620](#): aout\_ctrl\_pd\_vref\_slow = 0). Finally the central reference source for the analog audio system must be turned on ([Table 30–619](#): ain\_ctrl\_pd\_vcom\_vref1 = 0). It is important to do these steps in this order. After this the reference voltage can be slowly ramped up by setting aout\_ctrl\_vref\_slow\_up = 1 ([Table 30–620](#)). This will take approximately 0.5 s.

Now the analog audio path is ready for use. The volume must still be turned up, because the default is mute. It is recommended to do this in steps.

#### 4.4.2 Volume settings

The volume of the analog signal path can be set from 0 dB to -64.5 dB in 1.5 dB steps using the AOUT register (see [Table 30–620](#)).

Furthermore a mute setting is possible. The volume is set by 14 bits. The bits have been divided into two groups. The least significant 11 bits set the course volume (cvol in [Figure 31–103](#)). This volume can be set from 0 dB to -60 dB in 6 dB steps, and to mute. (fvol in [Figure 31–103](#)). The fine volume can be set from 0 dB to -4.5 dB in 1.5 dB steps.

**Table 638. AOUT register volume control bits**

AOUT register bits	Setting
<b>aout_ctrl_gain_avc[13:11] (AOUT_[29:27])</b>	<b>Fine volume</b>
111	0 dB
011	- 1.5 dB
001	- 3 dB
000 (default)	- 4.5 dB
<b>aout_ctrl_gain_avc[10:0] (AOUT_[26:16])</b>	<b>Coarse volume</b>
11111111111	0 dB
11111111110	- 6 dB
...	...
11000000000	- 54 dB
10000000000	- 60 dB
00000000000 (default)	mute

#### 4.4.3 Power-down sequence

First it is recommended to turn down the volume in steps.

After this the reference voltage can be slowly ramped down by setting [Table 30–620](#): aout\_ctrl\_vref\_slow\_up = 0. This will take approximately 0.5 s.

Then if the central reference source for the analog audio system is not needed for other circuits it can also be switched off ([Table 30–619](#): `ain_ctrl_pd_vcom_vref1 = 1`). If and only if, the central reference has been switched off, all the other blocks can be switched off ([Table 30–620](#): `aout_ctrl_pd_vref_slow = 1`; `aout_ctrl_pd_hp_l = 1`; `aout_ctrl_pd_hp_c = 1`; `aout_ctrl_pd_hp_r = 1`; `aout_ctrl_pd_anvc_l = 1`; `aout_ctrl_pd_anvc_r = 1`).

#### 4.5 Decimator/AGC function

The decimation filter is equipped with an Automatic Gain Control block (AGC). This function is intended, when enabled, to keep the output signal at a constant level.

The AGC can be used for microphone applications in which the distance to the microphone is not always the same.

The AGC can be enabled via the decimator control register DEC (see [Table 30–621](#)). In that case it bypasses the digital volume control. Via the same register also some other settings of the AGC can be made, like the attack/decay settings and the target level settings.

**Remark:** The DC filter in front of the decimation filter must be enabled when AGC is in operation, otherwise the output will be disturbed by the DC offset added in the ADC.

#### 4.6 Digital audio path

The following sections describe all the necessary steps to use the digital audio path. Normally the analog path will not be used then, so the analog audio path must be powered down ([Table 30–620](#): `aout_ctrl_pd_anvc_l = 1`; `aout_ctrl_pd_anvc_r = 1`). This automatically means that it is muted, but the -1.5 dB, -3 dB, and -4.5 dB volume steps can still be used. If the signal level is unclear the -1.5 dB volume step must be chosen to prevent clipping at 0 dBFS input signals. For all bits that are mentioned below, the default state is assumed as starting point.

##### 4.6.1 Power-up sequence

First the headphone amplifier can be turned on ([Table 30–620](#): `aout_ctrl_pd_hp_l = 0`; `aout_ctrl_pd_hp_c = 0`; `aout_ctrl_pd_hp_r = 0`). Then the reference buffer must be turned on ([Table 30–620](#): `aout_ctrl_pd_vref_slow = 0`). Finally the central reference source for the analog audio system must be turned on ([Table 30–619](#): `ain_ctrl_pd_vcom_vref1 = 0`).

To switch on the d/a converters the following needs to be done.

- First set the power-down sequence bit to enabled ([Table 30–623](#): `int_ctrl_pd_dac = 1`).
- Switch on the clocks ([Table 30–616](#): `pd_int_clk_ns = 0`; `pd_int_clk_dsp = 0`; `pd_aout_clk_dac = 0`).
- Switch on the d/a converters ([Table 30–620](#): `aout_ctrl_pd_sdac_l = 0`; `aout_ctrl_pd_sdac_r = 0`).
- Enable the switch ([Table 30–620](#): `aout_ctrl_swdac_on = 1`) and ramp up their output voltages ([Table 30–623](#): `int_ctrl_pd_dac = 0`).

This will take approximately 30 ms.

After this the reference voltage can be slowly ramped up by setting `aout_ctrl_vref_slow_up = 1`. This will take approximately 0.5 s.

Now the digital audio path is ready for use.

#### 4.6.2 D/A converter settings

Two bits can be used to set the bit format and the data weighted averaging algorithm, see bits [Table 30–620](#): aout\_ctrl\_pd\_set\_format and aout\_ctrl\_pd\_set\_dwa.

#### 4.6.3 Power-down sequence

First the reference voltage can be slowly ramped down by setting [Table 30–620](#): aout\_ctrl\_vref\_slow\_up = 0. This will take approximately 0.5 s.

After this the d/a converters must be switched off ([Table 30–623](#): int\_ctrl\_pd\_dac = 1). This will take approximately 30 ms. Then the rest can be switched off ([Table 30–620](#): aout\_ctrl\_sw\_dac\_on = 0; aout\_ctrl\_pd\_sdac\_l = 1; aout\_ctrl\_pd\_sdac\_r = 1; [Table 30–616](#): pd\_int\_clk\_ns = 1; pd\_int\_clk\_dsp = 1; pd\_aout\_clk\_dac = 1).

Then if the central reference source for the analog audio system is not needed for other circuits it can also be switched off ([Table 30–619](#): ain\_ctrl\_pd\_vcom\_vref1 = 1). If and only if, the central reference has been switched off, all the other blocks can be switched off ([Table 30–620](#): aout\_ctrl\_pd\_vref\_slow = 1; aout\_ctrl\_pd\_hp\_l = 1; aout\_ctrl\_pd\_hp\_c = 1; aout\_ctrl\_pd\_hp\_r = 1; aout\_ctrl\_pd\_anvc\_l = 1; aout\_ctrl\_pd\_anvc\_r = 1).

### 4.7 Headphone amplifier

As can be seen in [Figure 31–104](#) three output amplifiers are present. The center amplifier can be used as signal ground for the left and right channel speakers of a headphone. If this is not needed, the center amplifier can be powered down ([Table 30–620](#): aout\_ctrl\_pd\_hp\_c = 1). Next to the power-down bits for the three output amplifiers also some control and status bits are present. These are related to the output current limiters, which are present in the amplifiers. The bits can be found in [Table 31–639](#) and [Table 31–640](#).

**Table 639. Output current limiter settings**

aout_ctrl_set_limiter_l (AOUT_[11:10]) aout_ctrl_set_limiter_c (AOUT_[9:8]) aout_ctrl_set_limiter_r (AOUT_[7:6])	current limiter setting left/right	current limiter setting center
0	off	off
1 (default)	100 mA	200 mA
2	120 mA	240 mA
3 (default)	140 mA	280 mA

**Table 640. Clipping bits**

aout_ctrl_clip_l (AOUTDECINT_[26]) aout_ctrl_clip_c (AOUTDECINT_[25]) aout_ctrl_clip_r (AOUTDECINT_0[24])	clipping status
0	normal operation
1	output current clipped

#### 4.8 Slow reference buffer

The LPC315x provides a reference voltage source that can be powered-up and powered-down via an S-curve to prevent audible plops in audio speakers. This can be seen in [Figure 31–105](#).

Fig 105. S-curve at start-up

The curve is made up out of two RC-curves. The R value is 700  $\Omega$  nominal. The Capacitor has to be added externally. With a value of 47 mF, the RC-time is 33 ms. The overall power-up or power-down time is approximately  $10 \times RC$ .

## 5. Power optimization

In order to save power, clocks of unused blocks can be disabled.

The PLL clock frequency can be reduced in case the class AB amplifier on the analog die is used. In this case program the PLL at either  $1024 \times f_s$ ,  $512 \times f_s$  or  $256 \times f_s$ , depending on the sampling frequency  $f_s$ , and program the fractional dividers accordingly.

## 1. Introduction

---

This section describes the Power Supply Unit (PSU). The PSU provides the required power supplies to both the analog and digital circuits. It has been designed to operate on battery power, so current consumption and power efficiency have been optimized by using low power techniques and efficient switching regulators.

The PSU is an autonomous module that has its own controllers and oscillator. At power on (either battery or USB supplied), it will regulate all required voltages to a stable level after which it will reset the circuits attached to its outputs.

It features very low power-down current (<1  $\mu$ A) and high efficiency DCDC conversion (> 80% typical).

## 2. General description

---

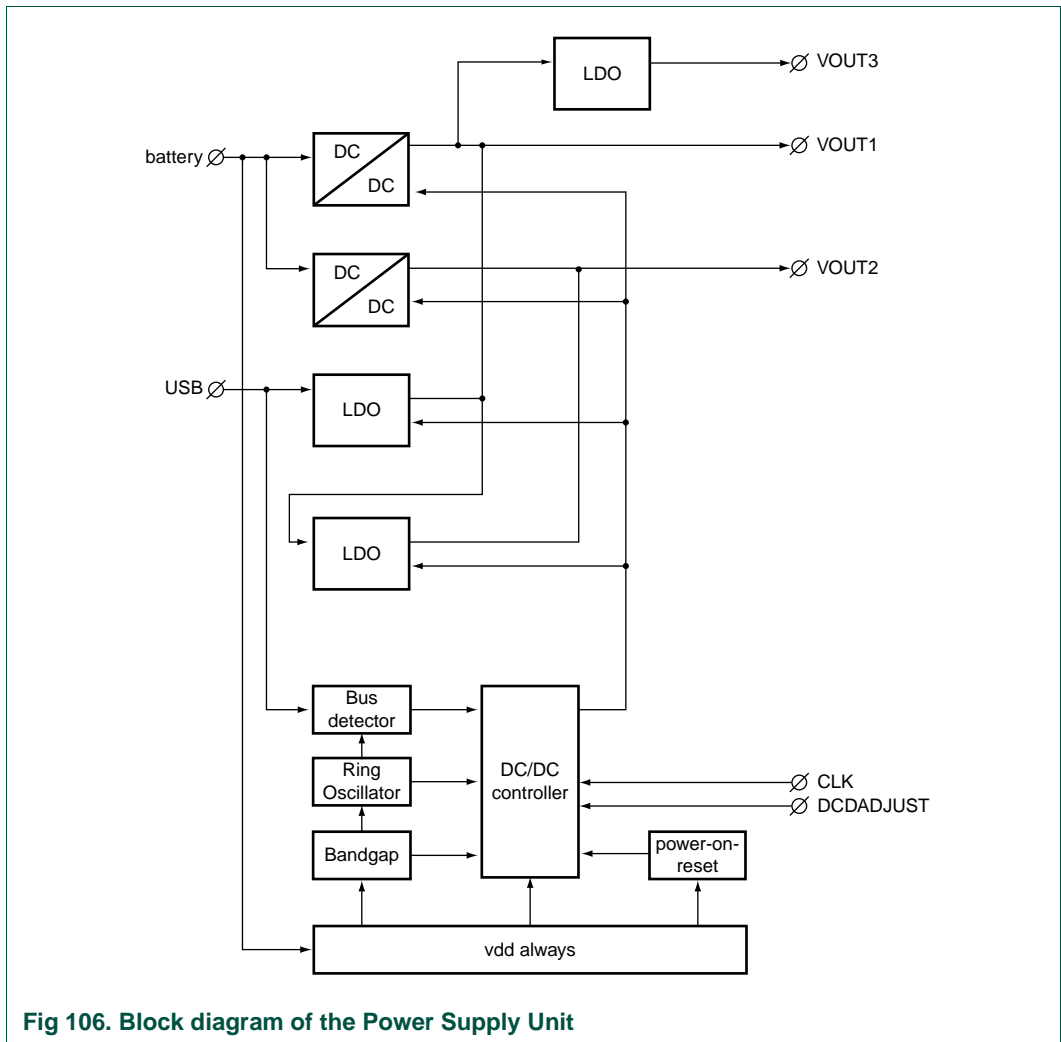

A block schematic of the Power Supply Unit (PSU) is shown in [Figure 32–106](#). Two switching dc/dc down-converters which will generate PSU\_VOUT1 (2.8 V) and PSU\_VOUT2 (1.15 V) from the battery. Additionally there are two continuous-time Low Drop Out regulators (LDO), one of which generates PSU\_VOUT1 from the USB supply. The other one generates PSU\_VOUT2 from PSU\_VOUT1, such that this regulator does not need to be 5 V capable. An additional LDO generates PSU\_VOUT3 that supplies a voltage of 1.4 V or 1.8 V (software selectable, see bit `dc/dc_ctrl_sel1v8` in register OTGDCLIC ([Table 30–612](#))). The input of this LDO is connected to PSU\_VOUT1.

A mixed-signal controller controls the switching cycles of the two switching converters by regularly comparing the output voltage with a reference voltage that is supplied by the bandgap. The output voltages can be adjusted by the core.

Additionally the controller will detect whether USB is present or not. If no battery voltage is present and USB is detected, then the USB is used as the supply. If both sufficient battery voltage is present and USB is detected, the USB supply is selected to be the supply by default, and the software has the control to switch over to battery (see bit `dc/dc_ctrl_ldo` in register OTGDCLIC ([Table 30–612](#))).

Because the controller is partly digital, a power-on-reset and a clock are needed. To ensure safe startup, the controller will use a local ring oscillator, issue a reset to the external world, and ignore all inputs during startup.

### 2.1 Block diagram

### 2.2 Pin connections

**Table 641. External signals to pins of the PSU**

Name	Type	Description
PSU_VBUS	Supply	PSU USB supply voltage
PSU_VOUT1	AO	PSU output1
PSU_LX1	AIO	PSU external coil terminal for output1
PSU_LX2	AIO	PSU external coil terminal for output2
PSU_VSS1	Ground	PSU ground
PSU_VIN1	AI	PSU output1 input voltage
PSU_VOUT2	AO	PSU output2
PSU_VOUT3	AO	PSU output3
PSU_VSSA	Ground	PSU ground

### 3. Register overview

Table 642. Register overview for PSU

Name	R/W	I <sup>2</sup> C1 address	Description	Reset value
OTGDCLIC	R/W	0x0000	PSU and Li-Ion charger control register (see <a href="#">Table 30–612</a> ).	
DCDCLIC	R	0x0001	PSU and Li-Ion charger status register (see <a href="#">Table 30–615</a> ).	
CGU_ANALOG	R/W	0x0002	Analog die CGU control register(see <a href="#">Table 30–616</a> ).	

### 4. Register description

See [Section 30–4.1 “Li-ion charger and PSU registers”](#) for the register bit description of the PSU.

### 5. Functional description

#### 5.1 Switching conversion

The switching Power Supply Units must be able to work with a Li-Ion cell. The battery has a voltage between 2.7 V and 4.2 V. The Power Supply Units are down-converters. This implies that the maximum voltage that can be converted to is equal to the battery voltage.

[Figure 32–107](#) shows an application diagram of the converter.

[Table 32–643](#) lists the prescribed external component specification.

**Table 643. DCDC external components specification**

External Component	Value	Comments
LLX1	22 $\mu$ H	DCR $\leq$ 0.1 $\Omega$ , ISAT>0.5A

Table 643. DCDC external components specification

External Component	Value	Comments
CVOUT1	22 $\mu$ F	0.1 $\Omega$ $\leq$ ESR $\leq$ 0.7 $\Omega$
LLX2	22 $\mu$ H	DCR $\leq$ 0.1 $\Omega$ , ISAT > 0.5 A
CVOUT2	22 $\mu$ F	0.1 $\Omega$ $\leq$ ESR $\leq$ 0.7 $\Omega$

## 5.2 Control of the switching PSU

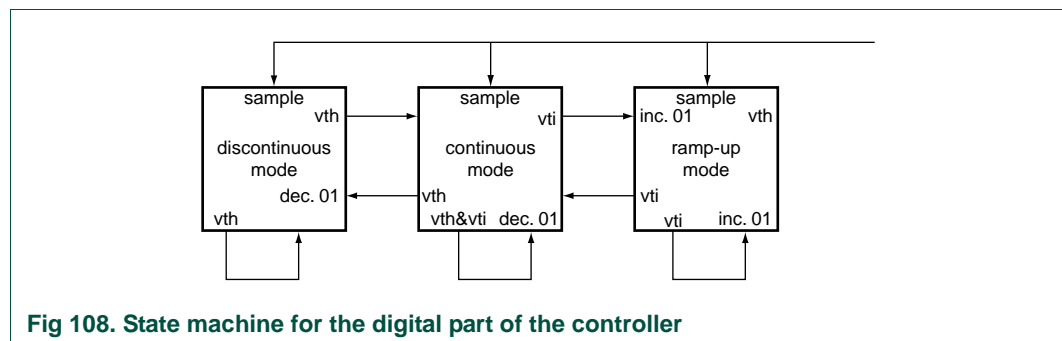

The controller is able to adapt the switching cycle to the load's requirements by choosing one of its three modes of operation:

Discontinuous mode: For low loads (up to several mA, the precise switching point depends on battery voltage and output voltage).

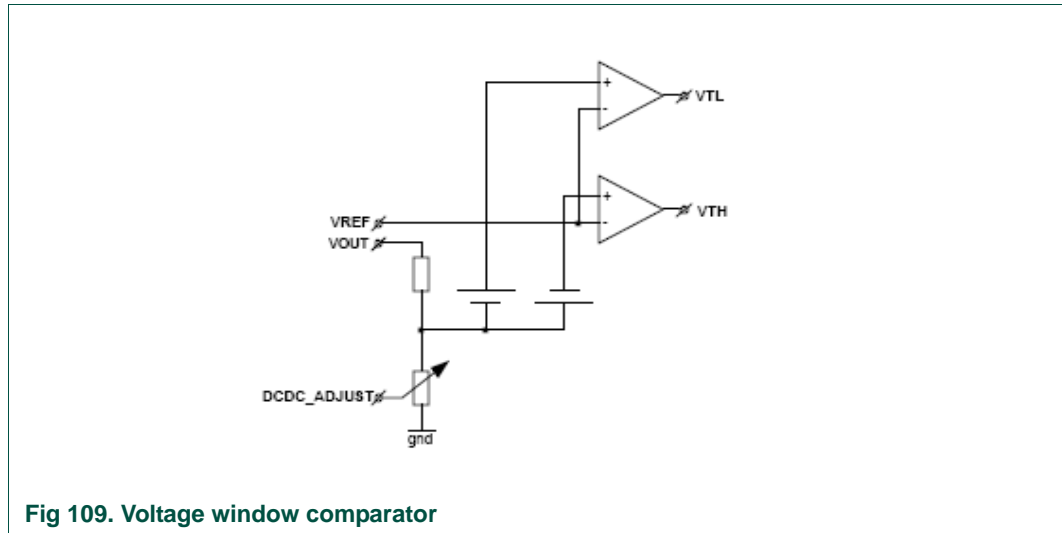

Continuous mode: For higher loads (tens of mA, precise switching point depends on battery voltage and output voltage).

Ramp-up mode: Enables the converter to react faster to a sudden increase in load current.

The digital part of the controller consists of a state machine that enables the controller to switch between modes. This is shown in [Figure 32–108](#). A decision to jump to a different state is taken on the basis of the outputs of the analog part. As a result of some of the jumps, the duration of the first phase of the cycle is increased or decreased.

The controller also consists of an analog part. The role of the analog part is to compare the output voltage with a programmable voltage window in 8 possible adjust settings. The role of the digital part is to compute the switching times such that the output voltage stays within this window. The principle of the window comparator is show in [Figure 32–109](#).

**Fig 109. Voltage window comparator**

The reference voltage is a fixed bandgap output voltage, the exact value of the resistor divider is determined by the settings of `dcdc_ctrl_dcdc1_adjust` and `dcdc_ctrl_dcdc2_adjust` (see [Table 30–613](#) and [Table 30–614](#)).

The window size (schematically drawn in the figure by two DC voltage sources) equals 50 mV.

When only  $V_{TH}$  is asserted that means that  $V_{OUT}$  is higher than the upper limit of the window, indicating to the digital part that the output voltage must be lowered. When only  $V_{TL}$  is asserted it indicates that  $V_{OUT}$  is lower than the lower limit of the window, telling the digital part to make the output voltage higher. When neither  $V_{TH}$  or  $V_{TL}$  is asserted,  $V_{in}$  is between the lower limit and the upper limit of the window. In that case the digital part does not need to change the output voltage. This is the normal mode of operation and it is called continuous mode because in this case the coil continuously carries current.

In continuous mode the digital part of the controller generates switching cycles at a fixed frequency. During the first part of such a cycle the coil current will ramp-up, during the second part it will ramp-down. The length of the first phase as a fraction of the cycle time is set such that the required output voltage is generated. When the output voltage runs outside the window this length is updated such that the output voltage falls within the window again.

A typical coil-current cycle is sketched in [Figure 32–110](#). The average coil current is equal to the average current demanded by the load. The lengths of the two phases are determined by the battery voltage and the output voltage of the Power Supply Unit.

**Fig 110. Example coil current cycle in continuous mode**

It is important to note again that the output voltage is allowed to vary within a certain window. This means that there will be a voltage ripple with a frequency that is largely correlated to the frequency content of the load current. The peak-peak amplitude of the ripple will be more or less equal to the window height. There will be ripple at the switching frequency too, this is mainly caused by the fact that the coil current will run through parasitic resistances of the load circuit, for example the ESR of the capacitor.

Apart from continuous mode there is discontinuous mode, in which the controller enters when there is little demand for energy (voltage rises to above the upper limit) and there is ramp-up mode; the controller enters this mode when there is an increased demand for energy (voltage falls to below the lower limit).

In discontinuous mode the coil current does not flow continuously. Dependent on energy demand a cycle is generated. So instead of changing the duty cycle like in continuous mode, in discontinuous mode the switching frequency is changed. This mode is intended for low-power operation. It is illustrated in [Figure 32–111](#). During the first phase the battery ramps up the current from zero value and during the second phase it is ramped down to zero by the load. The last part of the coil current is conducted to the load through the NMOST body diode in parallel to the ramp-down switch (the presence of this diode is inherent to the type of switching transistor that is used). The moment when the switches are to be opened is 'learned' from the behaviour of the Power Supply Unit in continuous mode. Instead of the NMOST body-diode the diode could be implemented by an external (Schottky) diode as well.

**Fig 111. Example coil current in discontinuous mode**

5.2.1 Analog part of the controller

The analog part of the controller is sketched in [Figure 32–112](#). In reaction to an assertion of PLAY or an assertion of VBUS the controller will generate an internal supply voltage. This voltage supplies several circuits: a bandgap, the reset generation, a local oscillator and a state machine.

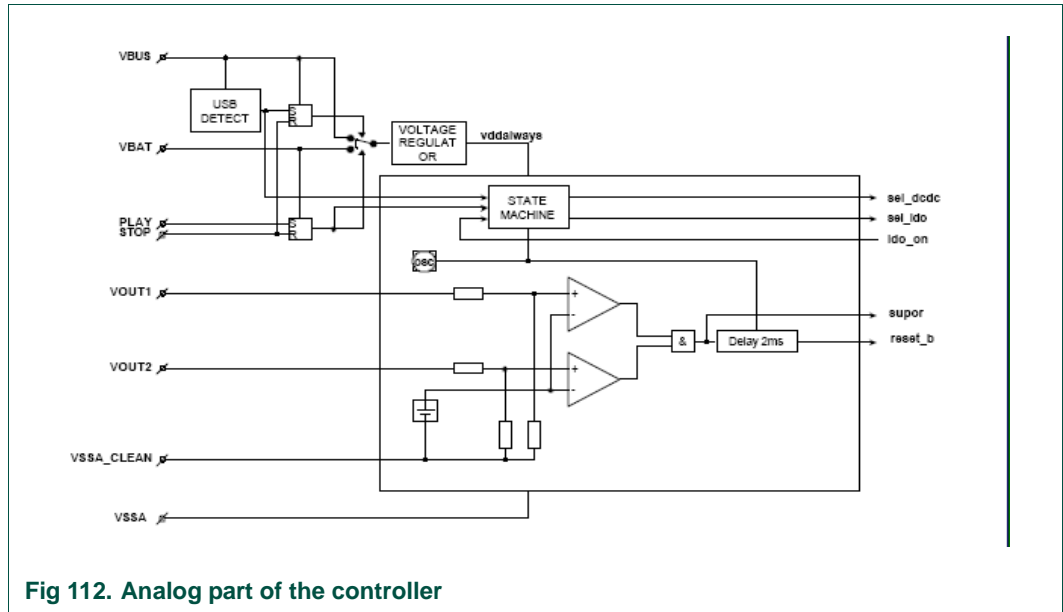

Fig 112. Analog part of the controller

The reset is generated from the output signals of two supply-detectors. At least two milliseconds after PSU\_VOUT1 and PSU\_VOUT2 have risen through a certain pre-set level, the reset\_b (reset connected to the digital die) output will be made HIGH (inactive). Otherwise reset\_b will be LOW (active). The state machine determines whether the power supply unit needs to generate its output voltages using the dcdc-converters or the LDOs. In order to decide the state machine needs input from the bus-detector, the output of the play latch and an input from the core called Ido\_on. This last signal is needed to decide when both play and USB are detected.

The state diagram of the state machine can be described with the following states:

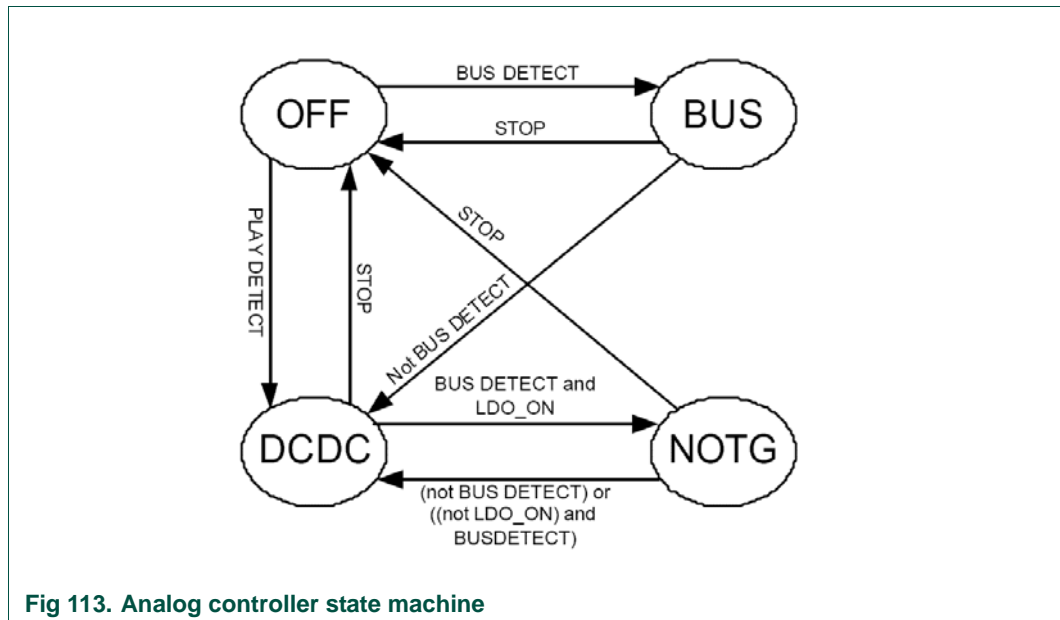

OFF, for the off state.

DCDC, for the case when the dcdc-converters are used.

BUS for the case when the system is powered from USB.

NOTG (abbreviation for Not On The Go) for the case when the system needs to be powered from the bus, while the DCDC is already running. Typically this is the case when USB is detected while the system is DCDC powered after the system (core) has determined that this USB voltage is not caused by its own USB-OTG charge pump.

The state machine shows the following behavior:

When the system is off:

PSU\_PLAY is pressed : switch on dcdc-converters automatically and generate a reset.

PSU\_STOP is pressed: no action.

vbus is detected: switch on LDOs automatically and generate a reset

When the system is running on dcdc-converters:

PSU\_PLAY is pressed: no action.

PSU\_STOP is pressed: switch off PSU.

vbus is detected: switch on LDOs after ldo\_on signal.

When the system is running on LDOs:

PSU\_PLAY is pressed: no action.

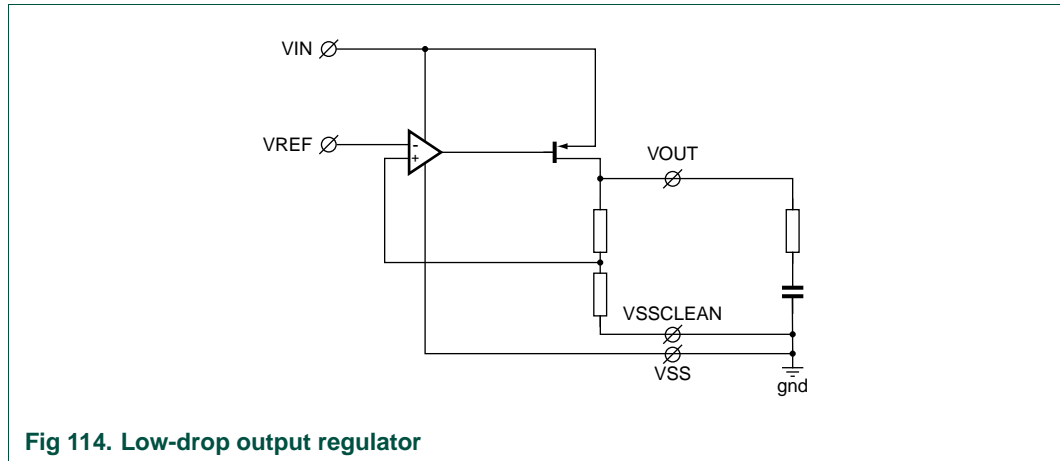

PSU\_STOP is pressed: switch off PSU.

vbus is removed: switch over to dcdc-converters automatically (no reset is generated).

ldo\_on is made inactive: switch over to dcdc-converters automatically (no reset is generated).

### 5.3 Linear voltage regulator

The (self biased) linear regulators will be implemented as Low Drop Out regulators for a fixed output voltage. The principle diagram is shown in [Figure 32–114](#).

One of the LDOs has to handle input signals in the order of 5.0 V so apart from the use of thick gate-oxide a special construction is used. The other LDOs handle an input signal of about 2.8 V; construction with just thick gate oxide is sufficient.

For the loop stability the choice is made that the dominant pole lies externally. This pole is determined by the external capacitor connected to VOUT in [Figure 32-114](#), which is in fact the same capacitor that is used in the dcdc-converter LC filter. The series resistance of C gives a zero and degrades the stability and thus is limited to a maximum value.

For an accurate output voltage a reference voltage VREF is needed. This voltage is made with a bandgap circuit.

#### 5.4 Use of an external (off-chip) PSU

To enable the use of an external power-supply, the reset\_b (reset connected to the digital die) will be high when the VBAT terminal is bonded to ground. In that case all other pins need to be bonded to ground as well.

## 1. Introduction

---

A battery charger is implemented on the analog die of the LPC315x microcontrollers. The charger is suitable for charging Li-ion batteries from the USB supply. Core functions of the charger are as follows:

- Trickle charging, with 10 % of the nominal current.
- Fast charging or constant current charging with the nominal current adjust by an external resistance value.
- Constant voltage charging to charge the battery on maximum capacity. Normally the current reduces in time from 100 % to 10 %. In some cases, the initial current can be higher and is limited to 120 %.

Functions for safety are:

- Current limiting in constant voltage charging. This function is always enabled.
- Current limiting by **chip** temperature. This function is enabled by bit `lic_ctrl_pontlim` in the OTGDCLIC register ([Table 30–615](#)). Temperature threshold and loop gain can be controlled through the OTGLIC register bits `lic_ctrl_tt_bit[2:0]` and `lic_ctrl_g_bit[2:0]` ([Table 30–615](#)).
- Current blocking by **battery** temperature sensing (`vntc`) (see [Section 33–5.3](#)). This function is enabled by bit `lic_ctrl_pontbat` in the OTGDCLIC register ([Table 30–615](#)).

The Li-ion charger is enabled by setting the `lic_ctrl_charge_enable` bit in the OTGDCLIC register ([Table 30–615](#)). Note that the clock to the Li-ion charger block needs to be enabled as well by setting `pd_lic_clk` to 0 in CGU\_ANALOG register ([Table 30–616](#)).

## 2. Battery charging aspects

---

Charging a Li-ion battery is a process that has to be monitored and controlled carefully for maximum battery charge and to protect the battery from damage. At any time, the state of the charger is communicated to the outside world through the DCDCCLIC status register ([Table 30–615](#)). These states are:

- `charger_on`
- `trickle_charge`
- `fast_charge`
- `cv_charge`
- `battery_full`
- `no_ntc`
- `tembat_ok`

The states are valid only when 'charger\_on' = 1. Software constructions can be imagined for logical transfers of one stage to another stage in a certain time. For example, a too long time duration of 'trickle\_charge', 'fast\_charge' or 'cv\_charge'. In that case, the software should know the capacity of the battery and the activity of the LPC315x (power consumption).

Battery manufactures prescribe a so called 'Constant-Current, Constant-Voltage' procedure for optimal loading where safety, charge capacity and lifetime are important. [Figure 33–115](#) shows the typical current and voltage of a battery that is charged. The charging process can take up to a few hours, dependent on:

- The initial state of the charge in the battery
- The nominal charge current
- The battery capacity

When after that the battery is full and the battery voltage decreases to less than 4.05 V, the charging is resumed.

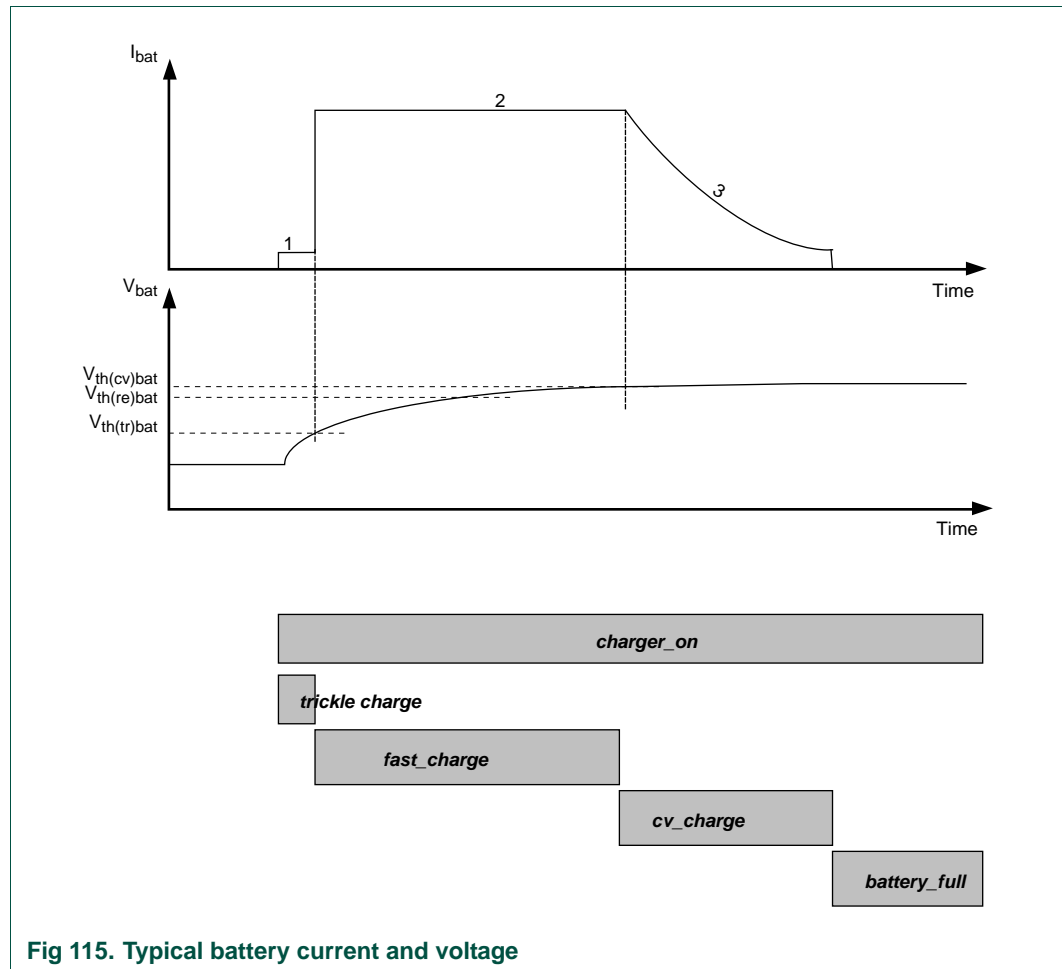

Fig 115. Typical battery current and voltage

There are three well-defined charge active states:

- Trickle Charge. Up to 2.8 VBAT.
- Constant Current Charge (called also Fast Charge). From 2.8 VBAT to 4.2 VBAT.

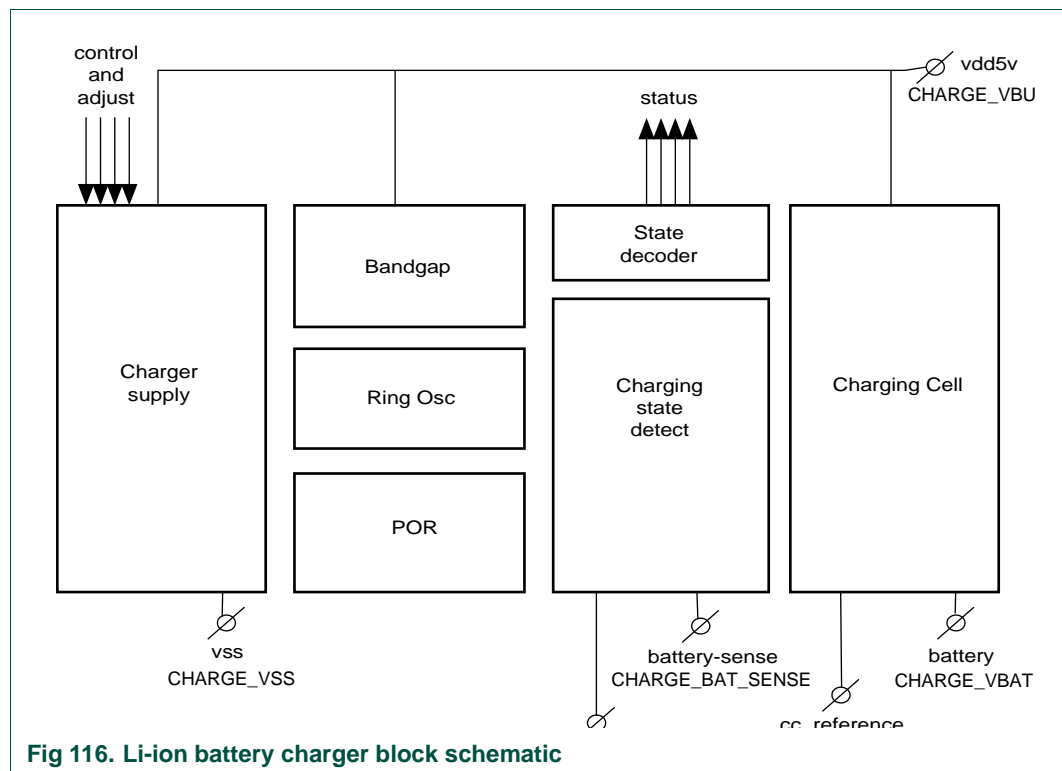

- Constant Voltage Charge. The current is down from 100 % to 10 %.

Assumed in the graph is that 'lit\_ctrl\_charge\_enable' is set to 1 in the OTGDCLIC register (see [Table 30-612](#)).

### 3. General description

[Figure 33-116](#) is the block schematic of the charger. The signal handling is dominantly from left to right.

#### 3.1 Interface description

##### 3.1.1 Clock signal

The Li-ion charger uses the 'lic\_clk' clock generated by analog CGU. Hence this clock should be enabled (by setting pd\_lic\_clk to 0 in CGU\_ANALOG register, [Table 30-616](#)) to use the charger function.

##### 3.1.2 Pin connections

**Table 644. Li-ion battery pin connections**

Name	Type	Description
CHARGE_VNTC	AI	NTC connection for battery temperature sensing
CHARGE_VSS	Ground	Li-ion charger ground, negative battery connection
CHARGE_VBUS	Supply	Li-ion charger 5 V supply

Table 644. Li-ion battery pin connections

CHARGE_BAT_SENSE	AI	Li-ion battery sense terminal (positive)
CHARGE_CC_REF	AO	Li-ion charger reference resistor

## 4. Register overview

Table 645. Register overview for Li-ion charger

Name	R/W	I <sup>2</sup> C1 address	Description	Reset value
OTGDCLIC	R/W	0x0000	PSU and Li-ion charger control register (see <a href="#">Table 30–612</a> ).	
DCDCLIC	R	0x0001	PSU and Li-ion charger status register (see <a href="#">Table 30–615</a> ).	
CGU_ANALOG	R/W	0x0002	Analog die CGU control register(see <a href="#">Table 30–616</a> ).	

## 5. Functional description

### 5.1 Battery current setting

The nominal charge current is set with a resistor between pins CHARGE\_CC\_REF and CHARGE\_VSS:

- Resistance value 1 k $\Omega$  gives a nominal charge current of 100 mA
- Resistance value of 400  $\Omega$  gives a nominal charge current of 250 mA. This is the maximum current setting

The resistor(s) connected to CHARGE\_CC\_REF determine the nominal charging current. The output current can be calculated with: 'Icharge\_nom' = 100/R. With a GPIO, the nominal current can be chosen between two values. In [Figure 33–117](#) these are 100 mA and 250 mA. The GPIO should be either zero or in tri-state and not high.

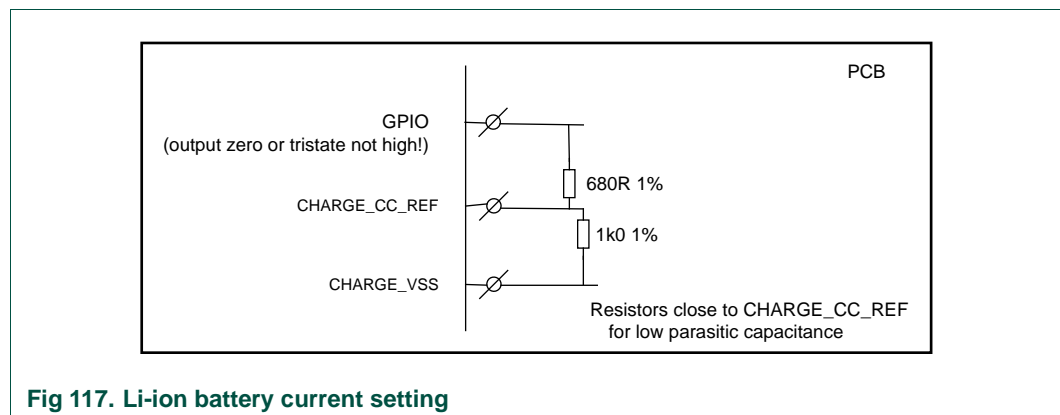

Fig 117. Li-ion battery current setting

### 5.2 Battery voltage sensing

For an accurate charging end-voltage, the connection CHARGE\_BAT\_SENSE should be connected as close as possible to the battery. A voltage drop over the CHARGE\_VBAT connection (100 mA to 250 mA) is then of no influence.

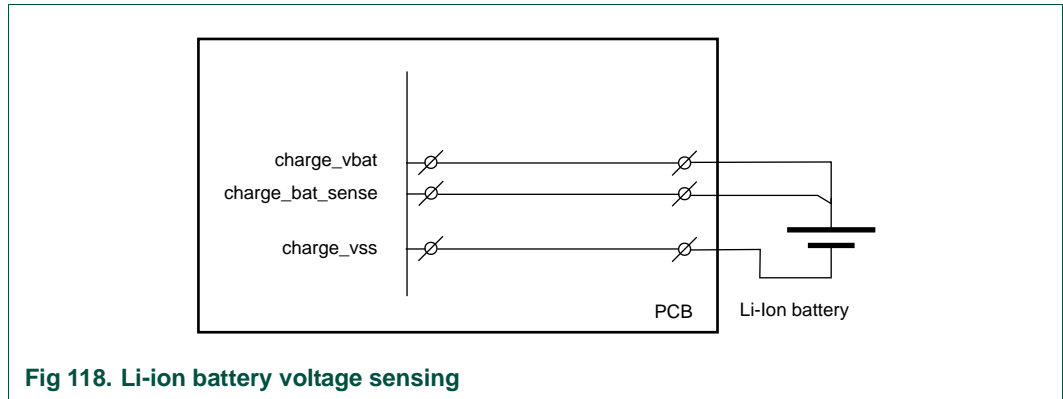

Fig 118. Li-ion battery voltage sensing

### 5.3 VNTC sensing for guarding the battery temperature

For monitoring battery temperatures, it is quite normal to use an NTC resistor. For the cold temperature limit a value of ~25 % of the VBUS is taken as threshold. For high temperatures this is ~6 %. Implemented is a small hysteresis.

Fig 119. VNTC sensing for guarding the battery temperature

Table 646. Design examples for value of R1 and R2; NTC van Vishay Dale 10 k

R1 = 56 k R2 = 82 k	Low off	Low on	High on	High off

## 1. Introduction

The Real-Time Clock (RTC) module can be used to provide the actual time and has a basic alarm function. It consists of a 32-bit counter that increments at the RTC clock frequency (1 Hz). Through an alarm register, interrupts can be issued on software programmable moments in time. The RTC is designed for low power consumption.

### 1.1 Features

- Provides time in seconds from a 32-bit up-counter (free running).
- One optional programming time interrupt (alarm).
- Ultra low-power design to support battery operation.
- Other parts of the chip may be powered down.
- Interrupt is also generated in Power-down mode.

## 2. General description

### 2.1 Block diagram

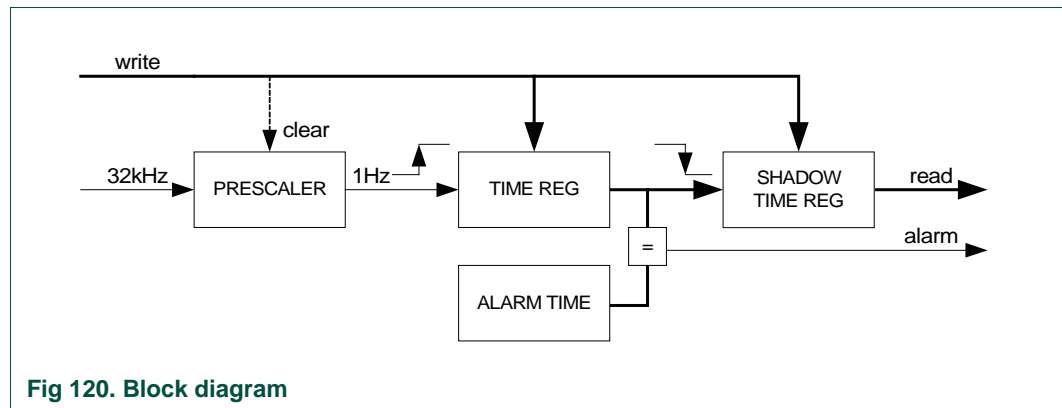

Fig 120. Block diagram

### 2.2 Pin connections

Table 647. RTC pin connections

Symbol	Type	Description
RTC_VDD36	Supply	2.7 V to 4.2 V battery supply (LDO input).
RTC_VSS	Ground	-
RTC_BACKUP	Supply	1.2 V to 1.95 V battery backup. Connected to gold cap (LDO output) LDO.
FSLOW_OUT	AO	Oscillator output.

Table 647. RTC pin connections ...continued

Symbol	Type	Description
FLOW_IN	AI	Oscillator input.
RTC_INT	AO	Alarm interrupt is an open-drain PMOS output in the battery supply domain to activate 'play'. On board it is recommended to connect the RTC_INT pin to the PSU_PLAY button to wake up the chip on an RTC alarm event.
RTC_CLK32	AO	RTC 32 kHz clock output for on-board applications such as tuner.

### 3. Register overview

Table 648. Register overview

Name	Access	I <sup>2</sup> C Address	Description	Reset value
RTC_TIME	R/W	0x0020	Time shadow register, incremented each second (see <a href="#">Table 30–627</a> ).	0x0000 0000
RTC_ALARM_TIME	R/W	0x0021	Alarm setting to activate the interrupt (see <a href="#">Table 30–628</a> ).	0x4343 CE50
RTC_STATUS	R	0x0022	Enable and status register for interrupts, clock un-set and shadow register status (see <a href="#">Table 30–629</a> ).	0x0001 2002
RTC_SET_ENA_STAT	W	0x0023	Set enable and status register (see <a href="#">Table 30–630</a> ).	-
RTC_CLR_ENA_STAT	W	0x0024	Clear enable and status register (see <a href="#">Table 30–631</a> ).	-

### 4. Register description

See [Section 30–4.5 “RTC registers”](#) for the bit description of the RTC registers.

### 5. Functional description

#### 5.1 Initialization of the RTC

The RTC does not require initialization for itself. When it starts up for the first time or when the BACKUP capacitor was empty, it will start up with the status TIME\_UNSET.

When TIME\_UNSET is high, the RTC has had an internal reset, such the settings are in the initial value (see tables). The RTC\_TIME counter starts counting from zero.

To have a proper actual time reference, software should write the actual time into the RTC\_TIME register.

#### 5.2 Epoch

The RTC\_TIME and RTC\_ALARM\_TIME registers are defined in seconds since epoch.

A time is converted easily into UTC by taking the quotient and modulus of the time register, modulo 86400. The quotient is the number of days since the epoch, and the modulus is the number of seconds since midnight UTC on that day.

From this the months and years can be calculated. Be aware of the leap years, each 4 years. In addition, irregular leap seconds exist.

Software often will use a standard 4 byte integer for this second count. This is 31 bits, storing a value of  $2^{31}$ . The remaining bit is often implemented as the sign. This means that when the second count reaches 2147483647dec (7FFFFFFh), it will wrap to -2147483648 dec.

It is advised to use the 32-bit value unsigned, such that the wrap-around is postponed for this 32-bits counter until 4294967295 (FFFFFFFFh). The counter will wrap around to 0 (00000000h).

### 5.3 Global function

The Time counter is incremented each second and is copied to the RTC\_TIME shadow register at the falling edge of the 1 Hz clock reference. Reading from this time shadow register by software causes a loss of 0.5 seconds from the actual time of the counter. Writing to the RTC\_TIME register will both update the time counter and also the time shadow register. The status TIME\_PENDING will be high, until the time is copied again from the time counter to the RTC\_TIME shadow register, 1.5 seconds afterwards.

The counter is based on a 32 kHz oscillator. Writing to the RTC\_TIME register will clear any initial offset and restarts dividing the 32 kHz to 1 Hz. Such it has an inaccuracy up to 30.5 ms.

When the time counter equals the RTC\_ALARM\_TIME, an alarm will be generated the next clock cycle (1 second afterwards), which can be read from the ALARM bit in the RTC\_STATUS register. The interrupt will activate the play button (as long as the RTC\_INT pin is connected to the PSU\_PLAY pin on board) when it is enabled (and such will power up the system when in sleep mode). Software has to check each play whether the user or the interrupt was activating 'play'. There is also an interrupt connected to the Event Router. In addition, these interrupts can be enabled. The interrupts are high active.

The alarm is generated 1.0 second after the time counter equals the alarm time. Time shadow register is lacking 0.5 seconds from the time counter. Therefore, when an interrupt occurs, the time shadow register equals still the alarm register for half a second.

### 5.4 Power-down and internal reset

The RTC has its own power domain. The power-domain crossing from digital power domain (VDDI\_AD) to RTC domain is done with level shifters with an enable port. Only when the system is powered up, the level shifters are enabled. Before powering down the system, the software needs to protect the RTC by writing the CGU register `cgu_ls_enable_off` ([Table 30-616](#)).

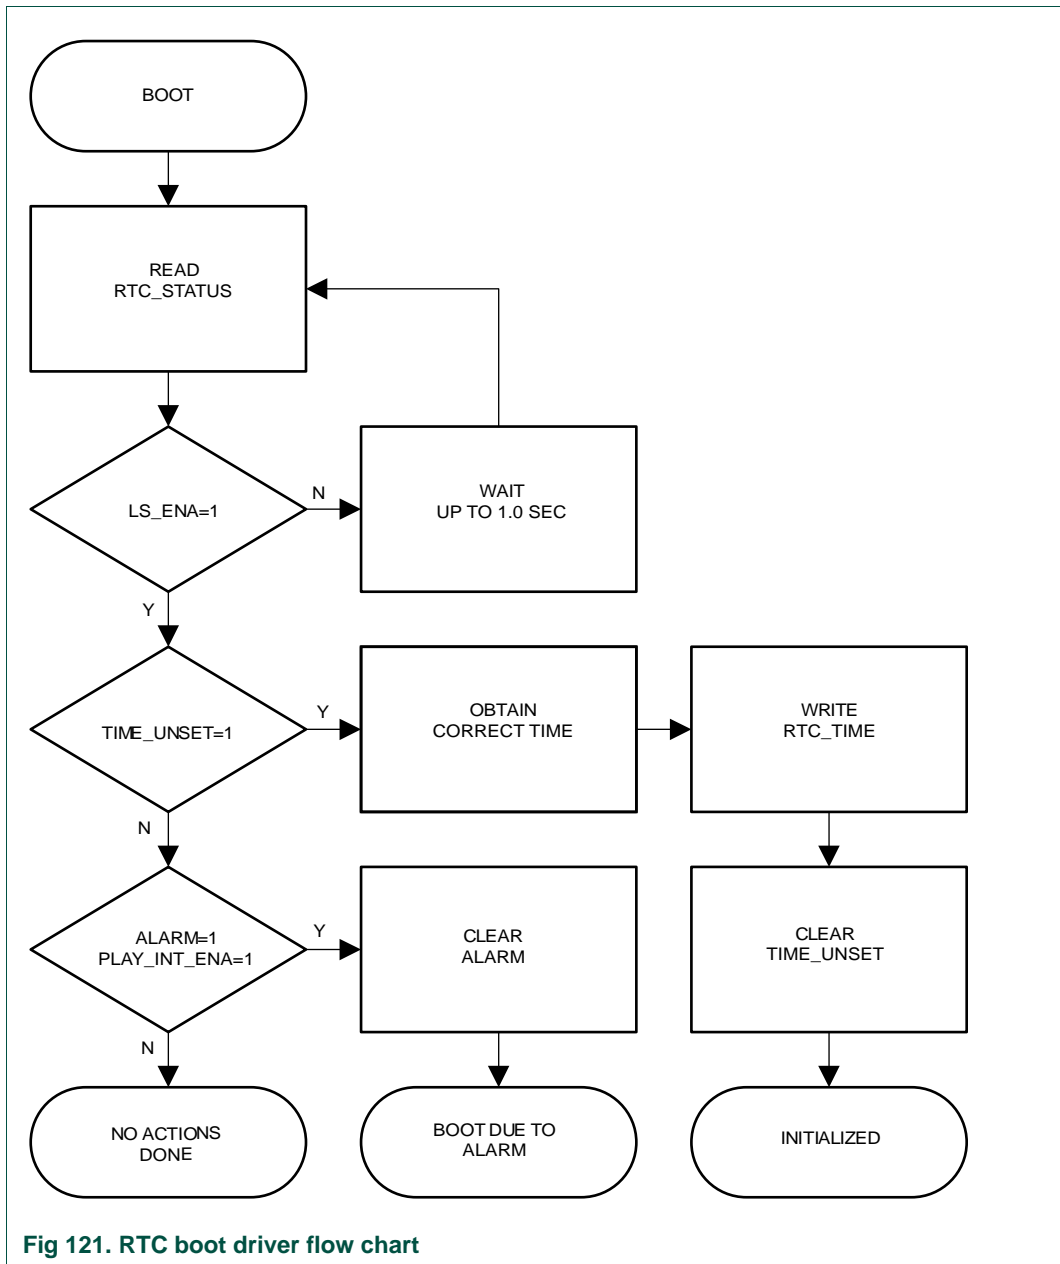

Activating the enable can last up to 1.0 second. By the LS\_ENA status bit it can be seen whether the enable is active, so software can access the RTC. When the RTC is not enabled, software only can read out the RTC\_STATUS register. Even when RTC\_TIME or RTC\_ALARM\_TIME is addressed for reading, it will return the RTC\_STATUS. Write actions to the RTC in such case will be ignored.

The RST\_RTC status bit is an indication of the RTC reset. In normal circumstances, the RTC will not be in reset. The RTC will be in reset only during power-up (first time there is a battery connected) or when the internal clock is not running yet. Write and read actions to the RTC will be ignored. The RTC\_STATUS register will return the default RTC\_STATUS.

## 5.5 RTC driver

### 5.5.1 Boot driver

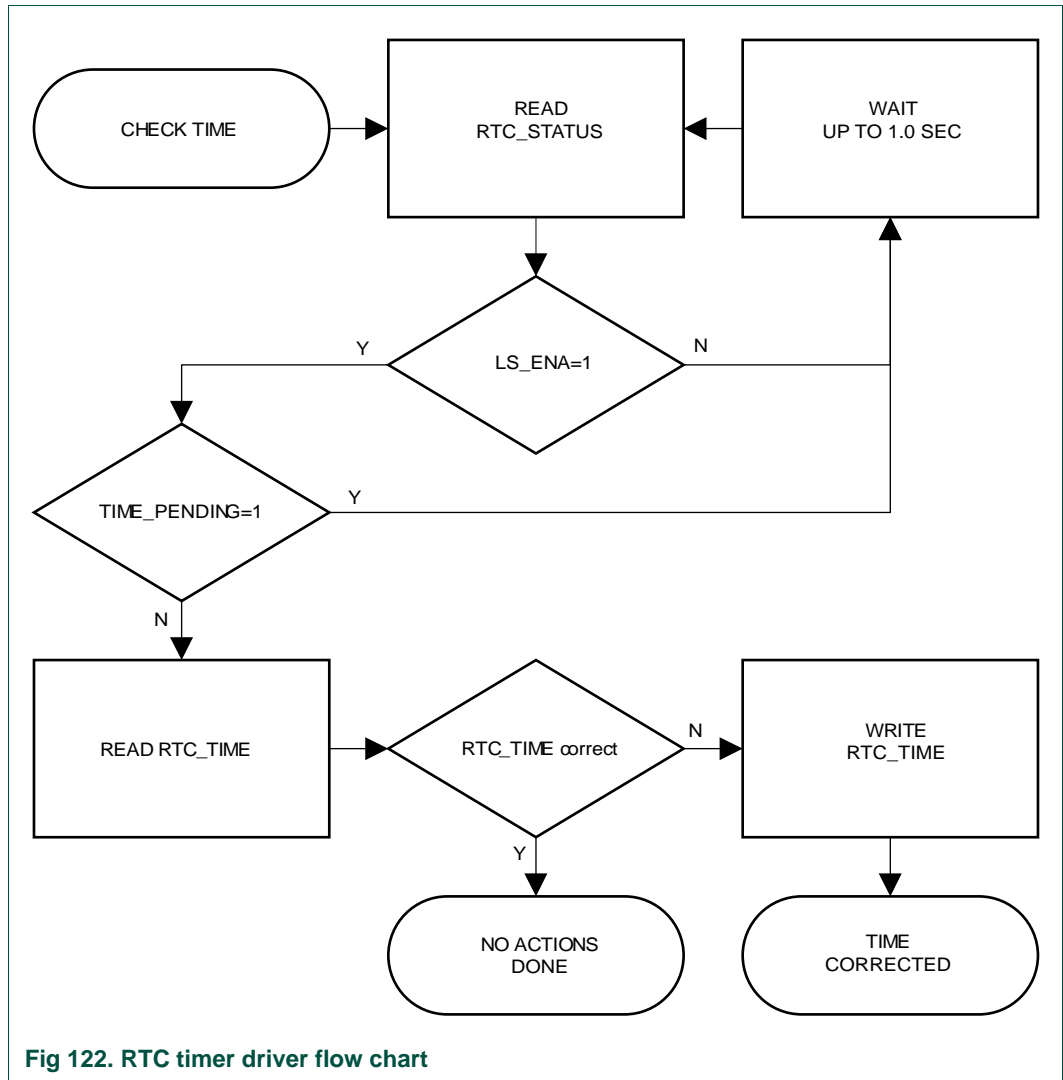

When the system boots up, the software should check whether the boot was caused by a user, pressing the play button, or whether the interrupt activated the play.

The wait state is not really required. As long the driver reads only the RTC\_STATUS register and does not try to write to any register in the RTC, the system can continue. When the TIME\_UNSET status is set, the correct time can be obtained. Writing this correct time into the RTC should be done after LS\_ENA is high. In addition, software can react when the RTC interrupt caused a boot up. Clearing this ALARM status bit should wait until LS\_ENA is high.

**5.5.2 Time driver**

When the system does a regular check on the actual time, the flow should match the next flow diagram.

**Fig 122. RTC timer driver flow chart**

Be aware that only the STATUS register can be read until the status bit LS\_ENA is high. Either writing to the RTC or reading other RTC registers is not supported.

There is a latency of 500 ms between the actual RTC time and the shadow register. Please be aware of the reading-out time with -0.5 seconds offset.

The time shadow register is only updated when the system clock of the register map is running. When this clock is switched off, the synchronization circuit is also switched off. It can take up to 1 second before it is synchronized again. The only way for software to check if it has been updated, is to wait 1 second or poll till it has been changed. The TIME\_PENDING status will likely (50%) fail in this mode.

## 6. Hardware interface

---

### 6.1 Power

The RTC has a local LDO to create the required power level in the backup goldcap. Therefore, the RTC can run independent from the other part of the chip.

The LDO will keep the backup-power level at 1.9 V (approx.). The internal RTC LDO switches off when the PSU is actively generating PSU\_VOUT1, PSU\_VOUT2 and PSU\_VOUT3. Hence it is recommended to connect a Schottky diode between PSU\_VOUT3 (1.8 V) and the RTC\_BACKUP pin so that the backup capacitor is charged to 1.8 V level even when the PSU is in active mode. When the PSU is not active, the RTC LDO will generate the required voltage (1.9 V) on the RTC\_BACKUP pin as long as the RTC\_VDD36 pin is connected to a battery (3.2 V to 4.2 V). When the battery goes below 3.2 V, the LDO stops functioning. The RTC will run for either another 2.0 hours on the remaining charge of the 0.2 F backup capacitor or until voltage drops below 1.2 V. Whenever the battery is either empty or removed, the LDO will block leakage from the backup capacitor to other devices connected to the battery. The POR will detect when power levels are too low and resets the RTC in the un-set state.

The register interface at the digital power domain can be powered down without affecting the RTC registers.

### 6.2 Reset

The RTC does not make use of the global reset. Because the POR of the power supply cannot detect when the backup is active still, the RTC does have its own internal POR. When the RTC is powered up (active at first start-up and each time the power back-up is empty), the POR will generate a reset pulse. The reset occurs when the voltage at BACKUP is above the trip-level of 1.3 V. This reset will set the registers to the initial values and will store the clock un-set status of the status register. This reset will be active at first start-up and each time the back-up goldcap is empty.

The system can be reset without affecting the RTC.

### 6.3 Clocking

The RTC has an embedded oscillator of 32.768 Hz. The low-power, low-frequency oscillator requires an external crystal on the pins FSLOW\_IN and FSLOW\_OUT. It functions as long as the backup-power level is above 1.2 V. The 32 kHz clock is divided to generate a 1.0 Hz clock.

The system clock and the 1.0 Hz clock are asynchronous. The system clock must be at least four (4) times faster than the 1.0 Hz to obtain oversampling. The synchronization between the time register and time shadow register does expect the clock to remain running. When the system clock was switched off, it can take up to 1 second before it is synchronized again.

#### 6.4 Open-drain interrupt

The RTC has an open-drain interrupt output to be able to power-up the system. This interrupt can be connected to the play button.

When the interrupt is active to the RTC\_INT, the battery voltage will appear at this output port. For other conditions the output is high impedance.

## 1. Introduction

For USB on-the-Go applications, the USB charge pump present on analog die generates the needed 5 V VBUS voltage using a battery supply voltage between 3.2 V and 4.2 V.

### 1.1 Features

- Generates a voltage between 4.4 V and 5.25 V.
- 80 mA maximum load current<sup>2</sup>. Implemented as a charge pump with pulse width modulation.
- Power-down mode.
- USB on-the-Go compliant.

## 2. General description

The USB charge pump needs a supply voltage between 3.2 V and 4.2V to generate a voltage of about 5 V, meant for USB on-the-Go applications. It is able to deliver an output current of 80 mA<sup>2</sup>. The charge pump charges an external capacitor by the battery and discharges it into the load, which consists of a least one capacitor. The switching frequency is fixed, 2 MHz, but due to the pulse width modulation, the duty cycle can change, depending on the load current. This pulse width modulation will result in a low ripple on the output voltage.

### 2.1 Interface description

#### 2.1.1 Clock signal

The USB charge pump uses the 'usbotg\_clk' clock generated by analog CGU. Hence this clock should be enabled (by clearing 'pd\_usbotg\_clk' (bit 9) in CGU\_ANALOG register, [Table 30–616](#)) to use the charge pump function. The USB charge pump is designed to operate using 2 MHz clock. The analog CGU generates the 'usbotg\_clk' clock by dividing the 'SYSCLK\_O' by 6. Hence software should always program the SYSCLK\_O (clock 91) in digital die CGU to source 12 MHz clock. The charge pump needs no external clock.

#### 2.1.2 Pin connections

CGU_ANALOG	R/W	0x0002	Analog die CGU control register (see <a href="#">Table 30–616</a> ).	

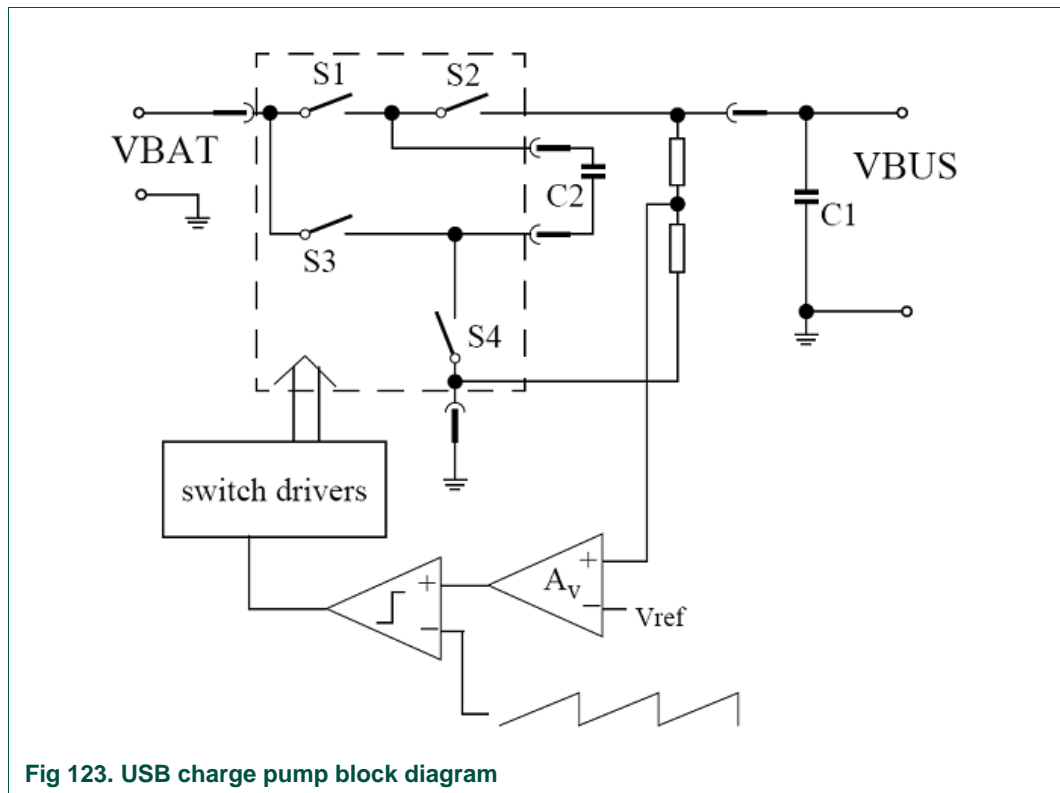

See [Section 32–4](#) for the register bit description of the USB charge pump control registers.

### 4. Functional description

#### 4.1 Basic functions

The USB charge pump is capable of delivering 5 V, 80 mA<sup>2</sup> to a B device. [Figure 35–123](#) shows the block diagram of the USB charge pump. The four switches S1, S2, S3 and S4 and the two capacitors C1 and C2 form a charge pump. When S1 and S4 are closed, C2 will be charged from the battery, and when S2 and S3 are closed, C@, now in series with the battery, is discharged into the VBUS output capacitor C1.

The output voltage is divided and compared with a reference level. The difference is amplified and used by a comparator to make a pulse width modulated signal. The pulse width modulated signal controls timing of the switch driver control logic.

## 4.2 Modes of operation

The USB charge pump has two modes, a power-down mode and a power-on mode.

In the power-down mode, the output of the USB charge pump is high-impedance, and the current consumption from the battery is very low (100 nA <sup>2</sup> under nominal conditions). To enter this mode the 'pd\_usbotg\_clk' (bit 9) bit in CGU\_ANALOG register, [Table 30–616](#), should be set.

In the power-on mode, the USB charge pump generates 5 V and it can deliver 80mA<sup>2</sup> to the load. To enter this mode the 'pd\_usbotg\_clk' (bit 9) bit in CGU\_ANALOG register, [Table 30–616](#), should be cleared.

## 5. Application schematic

### 5.1 USB OTG supply (used)

The application schematic in [Figure 35–124](#) shows how the USB OTG Supply is connected.

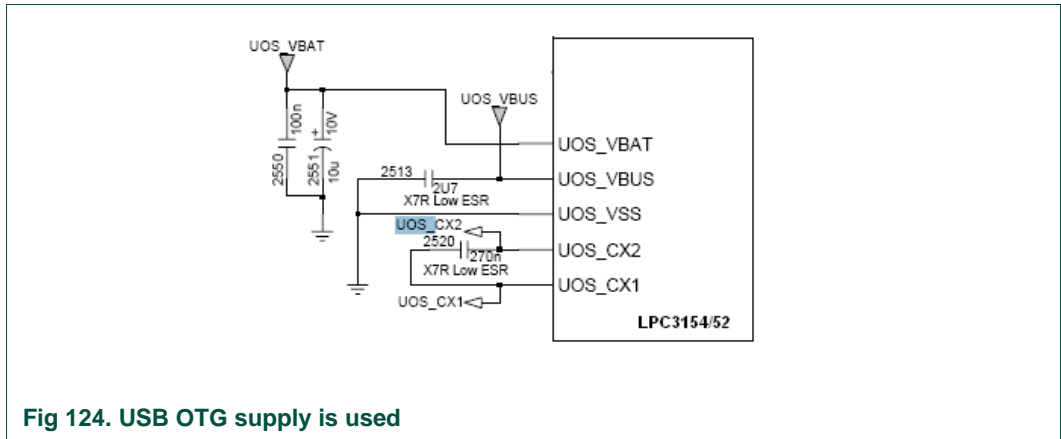

Fig 124. USB OTG supply is used

## 5.2 USB OTG supply (not used)

The application schematic in [Figure 35–125](#) shows how the USB OTG Supply is connected.

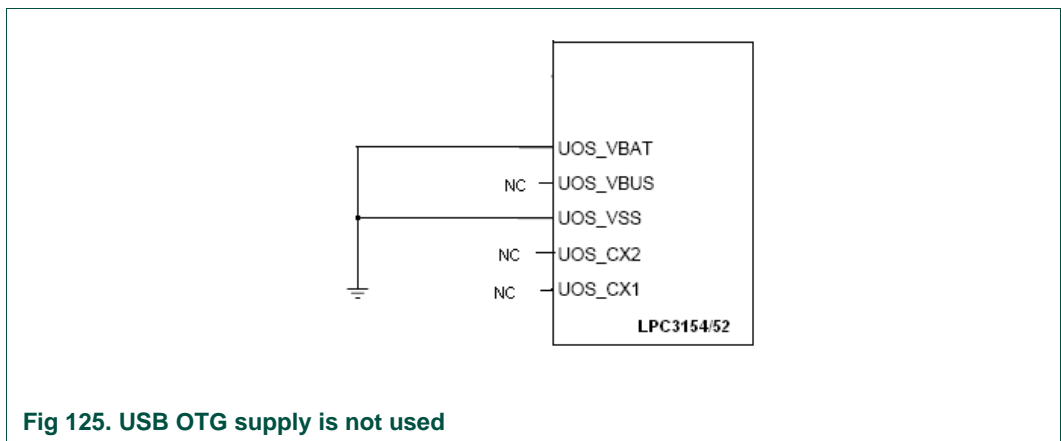

Fig 125. USB OTG supply is not used

## 1. Introduction

---

The JTAG Controller (JTAGC) module supports debug access to the ARM926 platform and tristate enable of the I/O pads. The overall strategy is to achieve good test and debug features without increasing the pin count and reducing the complexity of I/O muxing. The JTAG Controller is compatible with IEEE1149.1 Standard Test Access Port and Boundary Scan Architecture.

### 1.1 Features

The LPC315x has the following features:

- ARM926 debug access.
- Boundary scan.
- No target resources are required by the software debugger in order to start the debugging session.
- Allows the software debugger to talk via a JTAG (Joint Test Action Group) port directly to the core.
- Inserts instructions directly in to the ARM core.
- The ARM core or the system state can be examined, saved or changed depending on the type of instruction inserted.
- Allows instruction to execute at a slow debug speed or at a fast system speed.

**Remark:** JTAG access to the LPC315x can be disabled through the OTP block (see [Section 19–7.2](#)).

## 2. General description

---

The LPC315x Debug Architecture uses a JTAG port as a method of accessing the core. The scan chains that are around the core for production test are reused in the debug state to capture information from the databus and to insert new information into the core or the memory. There are three Test Access Port (TAP) controllers within LPC315x.

- Scan TAP: A JTAG-style TAP Controller controls the scan chains. With TAP\_ID 0x1541E02B.
- ARM TAP: TAP controller present within ARM926EJS core. With TAP\_ID 0x07926F0F.
- AD TAP: TAP controller present in the analog die. With TAP ID 0x1392E02B.

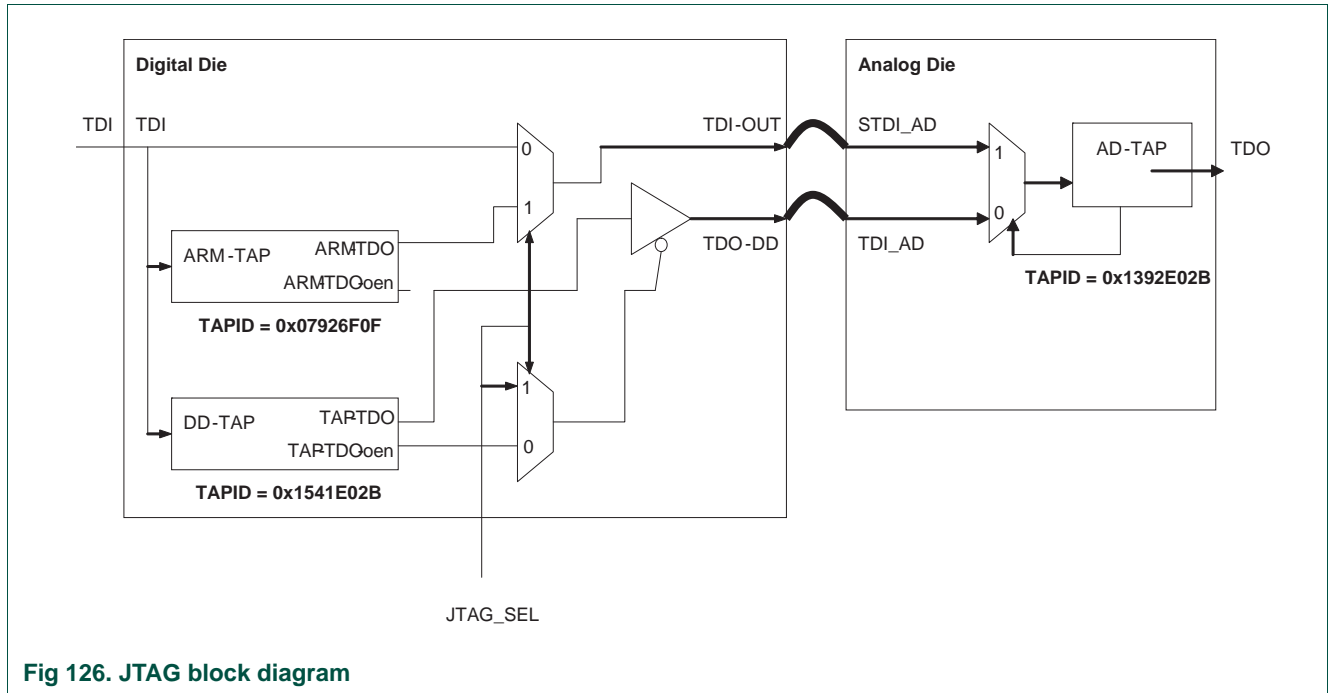

Fig 126. JTAG block diagram

As shown in the [Figure 36–126](#), the “JTAGSEL” pin controls which TAP controllers are enabled in scan chain.

When **JTAGSEL** = 0 (pull-down), **ARM\_TDO** is disabled and scan **TDO**s are enabled on both digital die and analog die.

When **JTAGSEL** = 1 (pull-up), **ARM\_TDO** is enabled and two TAP controllers appear in scan chain. The first TAP controller is **ARM-TAP** with **TAP\_ID**=0x07926F0F, **IR\_LEN**=4 and second is **AD-TAP** with **TAP\_ID**=0x1392E02B, **IR\_LEN**=5. ARM JTAG debug tools (such as U-link, J-link, Multi-ICE, RealView-ICE etc) should be programmed manually to reflect this scan chain connection to enable ARM debugging.

## 2.1 External pin connections

Table 651. External signals of the JTAG module

Pin name	Pin state after reset	Description
JTAGSEL	I:PD	JTAG selection. Controls which digital die TAP controller is configured in the JTAG chain along with the analog die TAP controller. Must be LOW during power-on reset.
TDI	I:PU	JTAG Data Input
TRST_N	I:PD	JTAG TAP Controller Reset Input. Must be low during power-on reset.
TCK	I:PD	JTAG Clock Input
TMS	I:PU	JTAG Mode Select Input
TDO	Z	JTAG <b>TDO</b> signal from Analog die TAP controller. Which Digital die TAP controller also in the JTAG chain is controlled by <b>JTAGSEL</b> .

### 2.2 JTAG considerations

The TRST\_N & JTAGSEL pins must be pulled low while the VDDI and VDDIOx power supplies are ramping up to ensure the ARM-TAP and SCAN-TAP controllers are reset and to ensure the IO cells come up in normal IO operation (not test mode). All JTAG input signals have either an internal weak pull-down or pull-up resistor to retain each signal in the proper state, therefore when no ARM JTAG debugging or Boundary Scan JTAG testing will be used the JTAG interface can be left disconnected, as shown in [Figure 36–127](#).

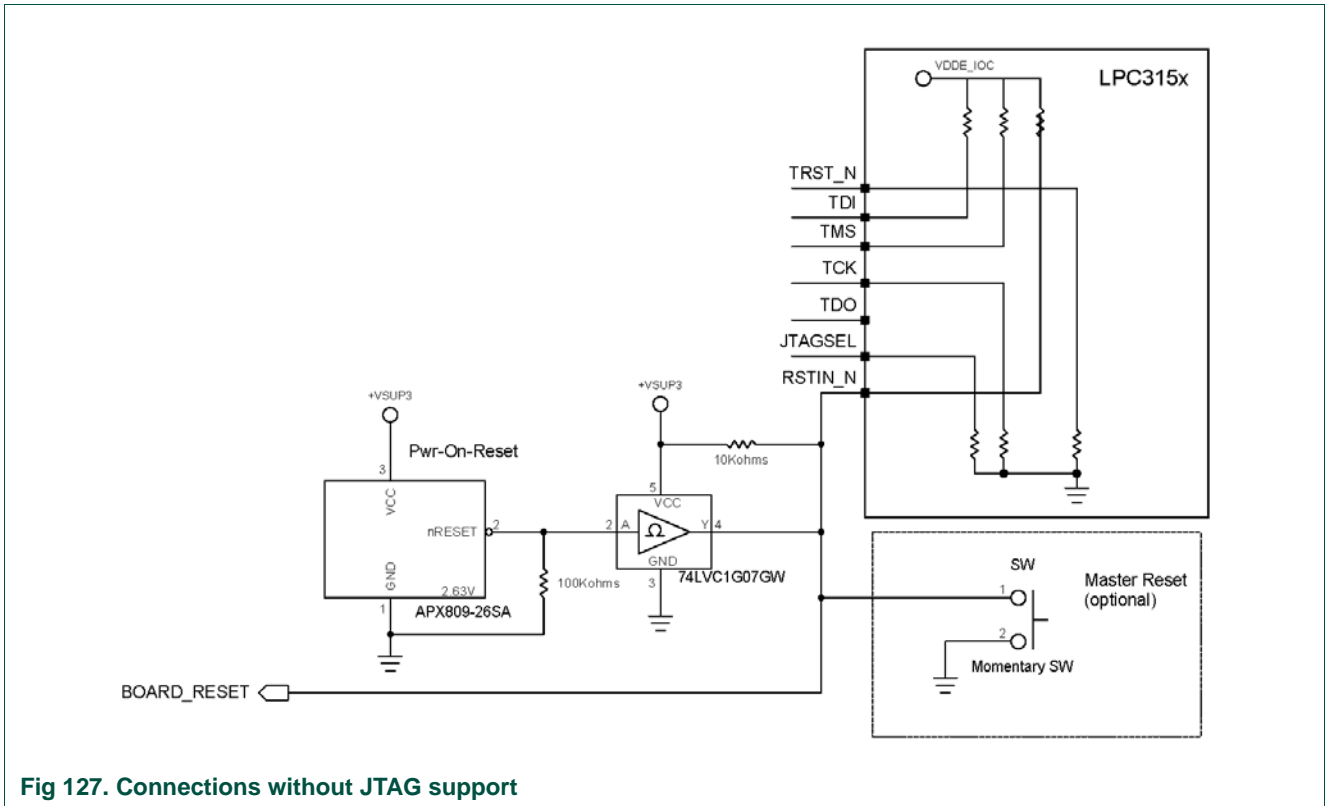

Fig 127. Connections without JTAG support

### 2.3 JTAG support circuit design

To support either ARM JTAG debugging or Boundary SCAN testing through JTAG, an external pull-up resistor is required on TRST\_N. For ARM JTAG debugging JTAGSEL will also require a pull-up resistor. A logic circuit is required to hold TRST\_N and JTAGSEL low while VDDI and VDDIOx power are ramping up. The LPC315x RSTIN\_N signal is open-drain, enabling the MCU to be reset from multiple sources (i.e. reset supervisor, ARM debugger, master switch, etc). Once the chip has been powered, the TRST\_N and JTAGSEL signals should not be reset when the ARM debugger resets the chip. The ARM JTAG debugging tool will typically monitor the RSTIN\_N signal to know when the MCU has been reset and also have the ability to pull the RSTIN\_N low to force a reset. The LPC315x will boot from the mode defined by GPIO0, GPIO1 and GPIO2 with JTAGSEL set for either ARM debug mode or Boundary Scan test / Bypass mode provided TRST\_N and JTAGSEL have been properly pulled low during power-on reset. The circuit in [Figure 36–128](#) provides the required signal resets while supporting either ARM debugging or Boundary Scan testing.

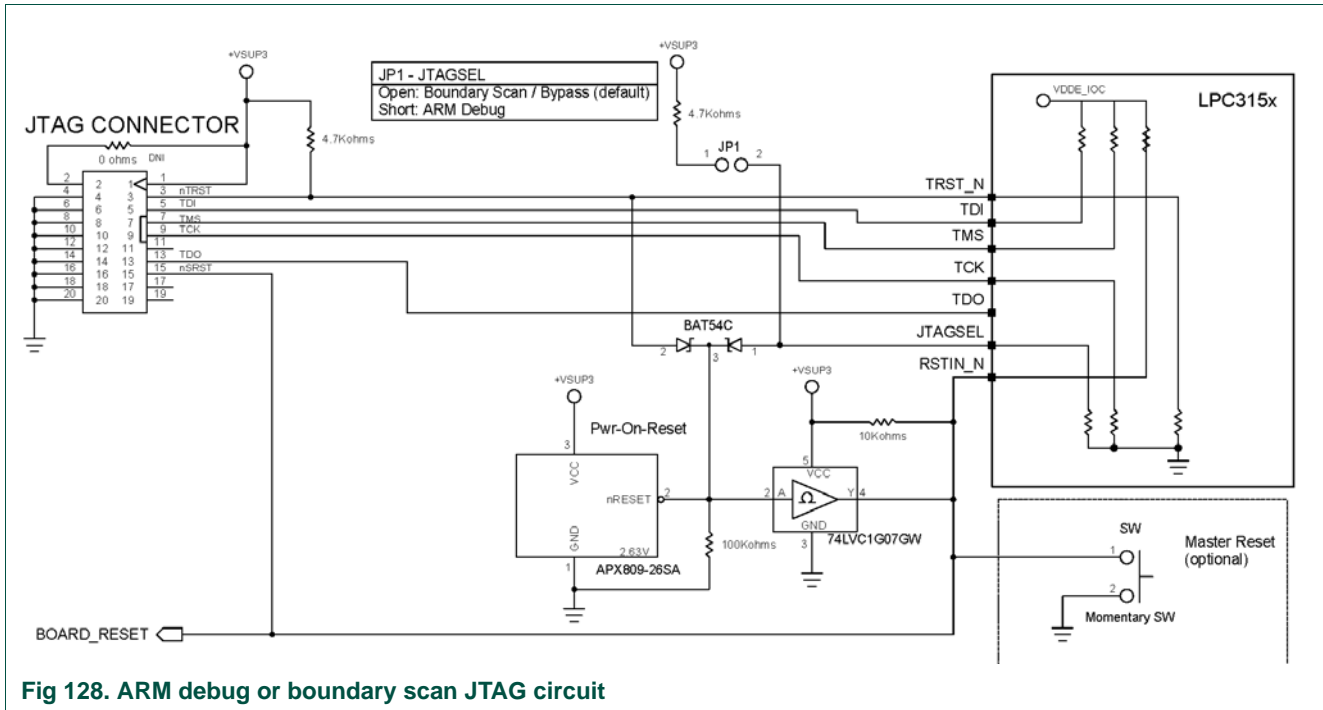

Fig 128. ARM debug or boundary scan JTAG circuit

## 2.4 Tool consideration

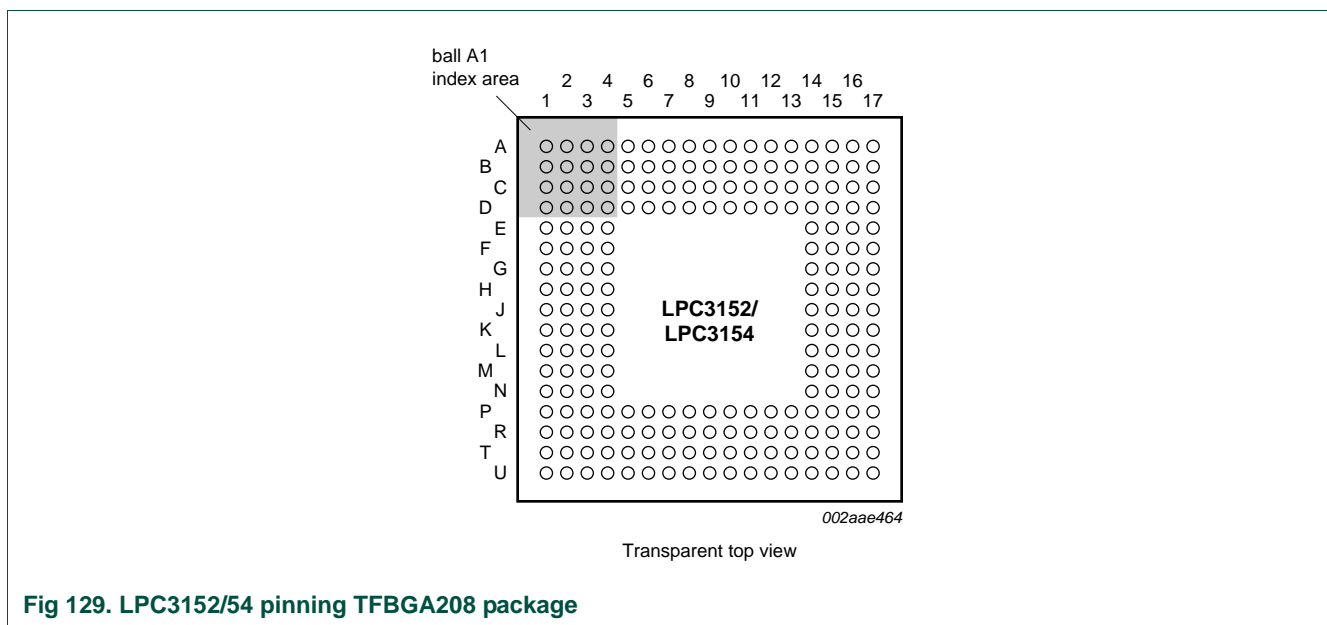

The following restrictions should be considered when using JTAG based debugging tools:

- The ARM JTAG clock is disabled by default after reset; it is enabled by boot ROM after chip initialization. So if you reset the chip through the debugger you need to configure the tool to give the boot ROM enough time (a few microseconds) to enable the clock before attempting to stop the processor.
- The boot ROM code on this chip is compiled in mixed mode (i.e. some sections are compiled in thumb mode and some in normal mode). Depending on when the debugger is attached the chip might stop when it is in thumb mode. Hence the thumb flag in Current Program Status Register (CPSR) should be cleared before executing any downloaded code.

### 1. Introduction

This chapter contains the pinning information for the LPC315x. The LPC315x employs a pin-multiplexing scheme to make an optimal selection of memories and peripherals possible.

### 2. Pinning information

[1] Digital IO levels are explained in [Table 37-654](#).

[2] I = input; I:PU = input with internal weak pull-up; I:PD = input with internal weak pull-down; O = output.

[3] Cell types are explained in [Table 37-655](#).

[4] Pin can be configured as GPIO pin in the IOCONFIG block.

[5] GPIO3 is driven HIGH if the boot process fails. It is recommended to connect GPIO3 to PSU\_STOP, so that the UM10315 will be powered down and further access prevented if the boot ROM detects an error.

[6] The UART flow control lines (mUART\_CTS\_N and mUART\_RTS\_N) are multiplexed. This means that if these balls are not required for UART flow control, they can be selected to be used for their alternative function: SPI chip select signals (SPI\_CS\_OUT1 and SPI\_CS\_OUT2).

- [7] The polyfuses get unintentionally burned at random if VPP is powered to 2.3 V or greater before the VDDI is powered up to minimum nominal voltage. This will destroy the sample, and it can be locked (security) and the AES key can be corrupted. For this reason it is recommended that VPP be powered by SUP1 at power-on.
- [8] To ensure that GPIO0, GPIO1 and GPIO2 pins come up as inputs, pins TRST\_N and JTAGSEL must be LOW at power-on reset, see *UM10315 JTAG chapter* for details.

**Table 654. Supply Domains**

Supply Domain	Voltage range	Related supply pins	Description
SUP1	1.0 V - 1.3 V	VDDI, VDDA12, HP_VDDA10, USB_VDDA12_PLL, USB_VDDA12_BG, VPP	Digital core supply
SUP2	1.4 V or 1.8 V	VDDI_3, ADC_VDDA18	Digital core supply
SUP3	2.7 V - 3.3 V	VDDE_IOC, VDDE_IOD, ADC10B_VDDA33, ADC_VDDA33, DAC_VDDA33, HP_VDDA33, USB_VDDA33_DRV, USB_VDDA33, VPP	Peripheral supply
SUP4	1.65 V - 1.95 V (in 1.8 V mode) 2.5 V - 3.6 V (in 3.3 V mode)	VDDE_IOA	Peripheral supply for NAND flash interface
SUP5	4.5 V - 5.5 V	PSU_VBUS, CHARGE_VBUS	USB VBUS voltage
SUP6	3.2 V - 4.2 V	RTC_VDD36, PSU_VBAT1, PSU_VBAT2, PSU_VBAT	Li-Ion battery voltage
SUP7	1.8 V	RTC_BACKUP	Real-time clock voltage domain (generated internally from SUP6)
SUP8	1.65 V - 1.95 V (in 1.8 V mode) 2.5 V - 3.6 V (in 3.3 V mode)	VDDE_IOB	Peripheral supply for SDRAM/SRAM/bus-based LCD <a href="#">[1]</a>

- [1] When the SDRAM is used, the supply voltage of the NAND flash, SDRAM, and the LCD interface must be the same, i.e. SUP4 and SUP8 should be connected to the same rail.

**Table 655: Cell types**

I/O pad name	Type	Function	Description
DIO1	bspts3chp	Digital input/output	Bidirectional 3.3 V; 3-state output; 3 ns slew rate control; plain input; CMOS with hysteresis; programmable pull-up, pull-down, repeater.
DIO2	bpts5pcph	Digital input/output	Bidirectional 5 V; plain input; 3-state output; CMOS with programmable hysteresis; programmable pull-up, pull-down, repeater.
DIO3	bpts5pcph1v8	Digital input/output	Bidirectional 1.8 V; plain input; 3-state output; CMOS with programmable hysteresis; programmable pull-up, pull-down, repeater.
DIO4	mem1 bsptz40pchp	Digital input/output	Bidirectional 1.8 or 3.3 V; plain input; 3-state output; CMOS with programmable hysteresis; programmable pull-up, pull-down, repeater.

CG2	vssis	Core ground	-
PG1	vsse	Peripheral ground	-

### 3. LCD/NAND flash/SDRAM multiplexing

The LPC315x contains a rich set of specialized hardware interfaces but the TFBGA package does not contain enough pins to allow use of all signals of all interfaces simultaneously. Therefore a pin-multiplexing scheme is created, which allows the selection of the right interface for the application.

Pin multiplexing is enabled between the following interfaces:

- between the dedicated LCD interface and the external bus interface.
- between the NAND flash controller and the memory card interface.
- between UART and SPI.
- between I2STX\_0 output and the PCM interface.

The pin interface multiplexing is subdivided into five categories: storage, video, audio, external bus, and UART related pin multiplexing. Each category supports several modes, which can be selected by programming the corresponding registers in the SysCReg.

Table 656. Pin descriptions of multiplexed pins

Pin Name	Default Signal	Alternate Signal	Description
<b>Video related pin multiplexing (controlled using <a href="#">Table 27–565 “SYSCREG_MUX_LCD_EBI_SEL(address 0x1300 2890)”</a>)</b>

mUART_CTS_N	UART_CTS_N	SPI_CS_OUT1	<b>UART_CTS_N</b> — UART modem control Clear-to-send signal. <b>SPI_CS_OUT1</b> — SPI chip select out for slave 1 (used in master mode).
mUART_RTS_N	UART_RTS_N	SPI_CS_OUT2	<b>UART_RTS_N</b> — UART modem control Request-to-Send signal. <b>SPI_CS_OUT2</b> — SPI chip select out for slave 2 (used in master mode).

### 3.1 Multiplexing between LCD and MPMC

The multiplexing between the LCD interface and MPMC allows for the following two modes of operation:

- MPMC-mode: SDRAM and bus-based LCD or SRAM.
- LCD-mode: Dedicated LCD-Interface.

The external NAND flash is accessible in both modes.

The block diagram [Figure 37–130](#) gives a high level overview of the modules in the chip that are involved in the pin interface multiplexing between the EBI, NAND flash controller, MPMC, and RAM-based LCD interface.

Figure 37–130 only shows the signals that are involved in pad-muxing, so not all interface signals are visible.

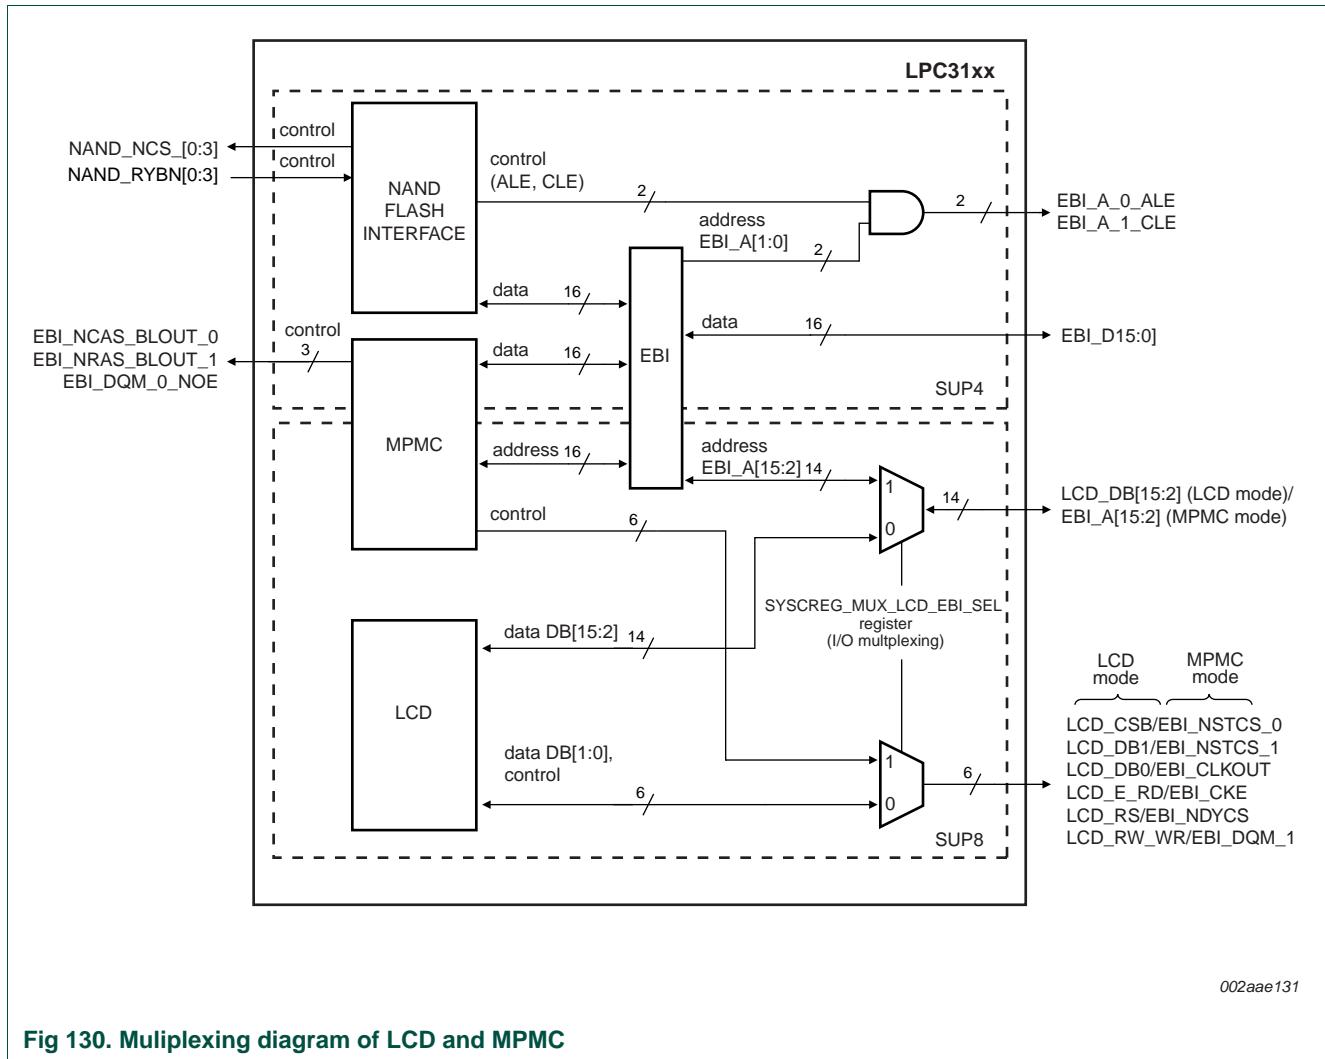

Fig 130. Multiplexing diagram of LCD and MPMC

The EBI unit between the NAND flash interface and the MPMC contains an arbiter that determines which interface is muxed to the outside world. Both NAND flash and SDRAM/SRAM initiate a request to the EBI unit. This request is granted using round-robin arbitration.

### 3.2 Supply domains

As is shown in Figure 37–130 the EBI (NAND flash/MPMC-control/data) is connected to a different supply domain than the LCD interface. The EBI control and address signals are muxed with the LCD interface signals and are part of supply domain SUP8. The SDRAM/SRAM data lines are shared with the NAND flash through the EBI and are part of supply domain SUP4. Therefore the following rules apply for connecting memories:

1. SDRAM and bus-based LCD or SRAM: This is the MPMC mode. The supply voltage for SDRAM/SRAM/bus-based LCD and NAND flash must be the same. The dedicated LCD interface is not available in this MPMC mode.

2. Dedicated LCD interface only: This is the LCD mode. The NAND flash supply voltage (SUP4) can be different from the LCD supply voltage (SUP8).

### 38.1 Abbreviations

Table 657: Abbreviations

Acronym	Description
ADC	Stereo Analog-to-Digital Converter for Audio
ADC10B	10-Bit Analog-to-Digital Converter
ANVC	Analog Volume Control
BIU	Bus Interface Unit
CGU	Clock Generation Unit
DFU	Device Firmware Upgrade
DMA	Direct Memory Access Controller
DRM	Digital Rights Management
ECC	Error Correction Code
I <sup>2</sup> C M/S	Inter IC Communication Master/Slave Interface
I <sup>2</sup> S	Inter-IC Sound
INTC	Interrupt Controller
IOCONFIG	Input Output Configuration
ROM	ROM Memory
IrDA	Infrared Data Association
ISRAM	Internal Static RAM Memory
JTAG	Joint Test Action Group
LCD	Liquid Crystal Display
PHY	Physical Layer
PLL	Phase Locked Loop
PWM	Pulse Width Modulation
RNG	Random Number Generator
SIR	Serial IrDA
SPI	Serial Peripheral Interface
SSI	Serial Synchronous Interface
Sysreg	System Control Registers
Timer	Timer module
UART	Universal Asynchronous Receiver Transmitter
USB 2.0 HS OTG	Universal Serial Bus 2.0 High Speed on the Go
WDT	WatchDog Timer

## 38.2 Legal information

### 38.2.1 Definitions

**Draft** — The document is a draft version only. The content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included herein and shall have no liability for the consequences of use of such information.

### 38.2.2 Disclaimers

**Limited warranty and liability** — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the *Terms and conditions of commercial sale* of NXP Semiconductors.

**Right to make changes** — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

**Suitability for use** — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected

to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

**Applications** — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

**Export control** — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

<b>3</b>	<b>Register overview</b> .....	<b>112</b>	4.3.2	USB Endpoint Prime register (ENDPTPRIME) .....		146
3.1	Use of registers .....	114	4.3.3	USB Endpoint Flush register (ENDPTFLUSH) .....		147
<b>4</b>	<b>Register description</b> .....	<b>115</b>	4.3.4	USB Endpoint Status register (ENDPSTAT) .....		148
4.1	Device/host capability registers .....	115	4.3.5	USB Endpoint Complete register (ENDPTCOMPLETE) .....		148
4.2	Device/host operational registers .....	117	4.3.6	USB Endpoint 0 Control register (ENDPTCTRL0) .....		149
4.2.1	USB Command register (USBCMD) .....	117	4.3.7	Endpoint 1 to 3 control registers (ENDPTCTRL1 to ENDPTCTRL3) .....		150
4.2.1.1	Device mode .....	117	<b>5</b>	<b>Functional description</b> .....		<b>152</b>
4.2.1.2	Host mode .....	118	5.1	OTG core .....		152
4.2.2	USB Status register (USBSTS) .....	121	5.2	Host data structures .....		152
4.2.2.1	Device mode .....	121	5.3	Host operational model .....		152
4.2.2.2	Host mode .....	123	5.4	ATX_RGEN module .....		152
4.2.3	USB Interrupt register (USBINTR) .....	125	5.5	ATX transceiver .....		153
4.2.3.1	Device mode .....	125	5.6	Modes of operation .....		153
4.2.3.2	Host mode .....	126	5.7	SOF/VF indicator .....		153
4.2.4	Frame index register (FRINDEX) .....	127	5.8	Hardware assist .....		154
4.2.4.1	Device mode .....	127	5.8.1	Auto reset .....		154
4.2.4.2	Host mode .....	127	5.8.2	Data pulse .....		154
4.2.5	Device address (DEVICEADDR - device) and Periodic List Base (PERIODICLISTBASE - host) registers .....	128	5.8.3	B-disconnect to A-connect (Transition to the A-peripheral state) .....		154
4.2.5.1	Device mode .....	128	<b>6</b>	<b>Deviations from EHCI standard</b> .....		<b>155</b>
4.2.5.2	Host mode .....	128	6.1	Embedded Transaction Translator function .....		155
4.2.6	Endpoint List Address register (ENDPOINTLISTADDR - device) and Asynchronous List Address (ASYNCLISTADDR - host) registers .....	129	6.1.1	Capability registers .....		156
4.2.6.1	Device mode .....	129	6.1.2	Operational registers .....		156
4.2.6.2	Host mode .....	129	6.1.3	Discovery .....		156
4.2.7	TT Control register (TTCTRL) .....	129	6.1.4	Data structures .....		157
4.2.7.1	Device mode .....	129	6.1.5	Operational model .....		157
4.2.7.2	Host mode .....	129	6.1.5.1	Micro-frame pipeline .....		157
4.2.8	Burst Size register (BURSTSIZE) .....	130	6.1.6	Split state machines .....		158
4.2.9	Transfer buffer Fill Tuning register (TXFILLTUNING) .....	130	6.1.7	Asynchronous Transaction scheduling and buffer management .....		158
4.2.9.1	Device controller .....	130	6.1.8	Periodic Transaction scheduling and buffer management .....		158
4.2.9.2	Host controller .....	130	6.1.9	Multiple Transaction Translators .....		159
4.2.10	BINTERVAL register .....	131	6.2	Device operation .....		159
4.2.11	USB Endpoint NAK register (ENDPTNAK) .....	132				
4.2.11.1	Device mode .....	132				
4.2.11.2	Host mode .....	132				

6.2.1	USBMODE register	159	8.7.1	Interrupt/bulk endpoint bus response matrix	176
6.2.2	Non-Zero Fields the register file	159	8.8	Control endpoint operational model	176
6.2.3	SOF interrupt	160	8.8.1	Setup phase	176
6.3	Miscellaneous variations from EHCI	160	8.8.1.1	Setup Packet Handling using setup lockout mechanism	177
6.3.1	Discovery	160	8.8.1.2	Setup Packet Handling using trip wire mechanism	177
6.3.1.1	Port reset	160	8.8.2	Data phase	178
6.3.1.2	Port speed detection	160	8.8.3	Status phase	178
<b>7</b>	<b>Device data structures</b>	<b>161</b>	8.8.4	Control endpoint bus response matrix	178
7.1	Endpoint queue head (dQH)	161	8.9	Isochronous endpoint operational model	179
7.1.1	Endpoint capabilities and characteristics	162		TX packet retired	180
7.1.2	Transfer overlay	163		RX packet retired	180
7.1.3	Current dTD pointer	163	8.9.1	Isochronous pipe synchronization	180
7.1.4	Set-up buffer	164	8.9.2	Isochronous endpoint bus response matrix	181
7.2	Endpoint transfer descriptor (dTD)	164	8.10	Managing queue heads	181
7.2.1	Determining the number of packets for Isochronous IN endpoints	166	8.10.1	Queue head initialization	182
	Example 1	166	8.10.2	Operational model for setup transfers	182
	Example 2	167	8.11	Managing transfers with transfer descriptors	183
<b>8</b>	<b>Device operational model</b>	<b>167</b>	8.11.1	Software link pointers	183
8.1	Device controller initialization	167	8.11.2	Building a transfer descriptor	183
8.2	Port state and control	168	8.11.3	Executing a transfer descriptor	184
8.3	Bus reset	170		Link list is empty	184
8.4	Suspend/resume	171		Link list is not empty	184
8.4.1	Suspend	171	8.11.4	Transfer completion	184
8.4.1.1	Operational model	171	8.11.5	Flushing/De-priming an endpoint	185
8.4.2	Resume	171	8.11.6	Device error matrix	185
8.5	Managing endpoints	172	8.12	Servicing interrupts	186
8.5.1	Endpoint initialization	172	8.12.1	High-frequency interrupts	186
8.5.2	Stalling	173	8.12.2	Low-frequency interrupts	186
8.5.3	Data toggle	173	8.12.3	Error interrupts	186
8.5.3.1	Data toggle reset	173	<b>9</b>	<b>USB power optimization</b>	<b>187</b>
8.5.3.2	Data toggle inhibit	173	9.1	USB power states	187
8.6	Operational model for packet transfers	174	9.2	Device power states	188
8.6.1	Priming transmit endpoints	174	9.3	Host power states	190
8.6.2	Priming receive endpoints	175	9.4	Susp_CTRL module	191
8.7	Interrupt/bulk endpoint operational model	175			

**Chapter 9: LPC315x DMA controller**

<b>1</b>	<b>Introduction</b>	<b>193</b>	<b>5</b>	<b>Functional description</b>	<b>208</b>
1.1	Features	193	5.1	Channel arbitration	208
<b>2</b>	<b>General description</b>	<b>194</b>	5.2	Scatter gathering / Building a linked-list	208
2.1	Interface description	194	5.2.1	Ending a linked-list transfer inside the linked list	211
2.1.1	Clock signals	194	5.2.2	To start a linked-list operation	211
2.1.2	Bus interface	194	5.2.3	Ending a linked list transfer in the middle of a linked-list execution	211
2.1.3	Interrupt request signals	194	5.3	DMA flow control	212
2.1.4	Reset Signals	195	5.4	Connectivity	213
2.1.5	Internal signals of the DMA module	195	5.4.1	Using FIFO level slaves, which have no flow control	213
<b>3</b>	<b>Register overview</b>	<b>196</b>	5.5	External enable flow control	214
<b>4</b>	<b>Register description</b>	<b>201</b>	<b>6</b>	<b>Power optimization</b>	<b>215</b>
4.1	Channel registers 0 to 11	201			
4.2	Alternate channel registers 0 to 11	204			
4.3	General control registers	205			

**Chapter 10: LPC315x Interrupt controller**

<b>1</b>	<b>Introduction</b>	<b>216</b>	2.1	Interface description	217
<b>2</b>	<b>General description</b>	<b>216</b>	2.1.1	Clock signals	217

2.1.2	Interrupt request signals . . . . .	217	4	<b>Register description . . . . .</b>	<b>223</b>
2.1.2.1	Processor Interrupt Request Inputs . . . . .	217	4.1	Interrupt Priority Mask Register . . . . .	223
2.1.2.2	Processor Interrupt Request Outputs . . . . .	217	4.2	Interrupt Vector Register . . . . .	224
2.1.3	Reset signals . . . . .	218	4.3	Interrupt Pending Register . . . . .	225
2.1.4	DMA transfer signals . . . . .	218	4.4	Interrupt Controller Features Register . . . . .	226
2.2	Available interrupts . . . . .	218	4.5	Interrupt Request Registers . . . . .	226
2.3	Block diagram . . . . .	220	5	<b>Functional description . . . . .</b>	<b>229</b>
2.4	Short Description of sub blocks . . . . .	220	5.1	Why Vectored? . . . . .	229
2.4.1	Input Stage . . . . .	220	5.2	Interrupt Targets . . . . .	230
2.4.2	Priority Masking Stage . . . . .	221	5.3	Interrupt Priority . . . . .	230
2.4.3	Output Stage . . . . .	221	6	<b>Power optimization . . . . .</b>	<b>230</b>
2.4.4	Vector Stage . . . . .	221	7	<b>Programming guide . . . . .</b>	<b>230</b>
3	<b>Register overview . . . . .</b>	<b>222</b>	7.1	Software interrupts . . . . .	230

**Chapter 11: LPC315x AHB-to-APB bridge**

1	<b>Introduction . . . . .</b>	<b>231</b>	4	<b>Detailed architecture and functional modes description . . . . .</b>	<b>232</b>
1.1	Features . . . . .	231	4.1	Memory Endianess . . . . .	232
2	<b>General description . . . . .</b>	<b>231</b>	4.2	Data Steering . . . . .	232
2.1	Block diagram . . . . .	231	4.3	Write Buffer . . . . .	233
2.2	Interface description . . . . .	232	4.4	Address Alignment . . . . .	233
2.2.1	Clock Signals . . . . .	232	5	<b>Power optimization . . . . .</b>	<b>233</b>
2.2.2	Reset signals . . . . .	232	6	<b>Programming guide . . . . .</b>	<b>233</b>
3	<b>Register overview . . . . .</b>	<b>232</b>			

**Chapter 12: LPC315x AHB multi-layer matrix**

1	<b>Introduction . . . . .</b>	<b>234</b>	2.1.2	Reset Signals . . . . .	237
1.1	Features . . . . .	234	2.1.3	System control register (Syscreg) signals . . . . .	237
1.2	About AHB and multilayer AHB . . . . .	235	3	<b>Register overview . . . . .</b>	<b>238</b>
2	<b>General description . . . . .</b>	<b>236</b>	4	<b>Register description . . . . .</b>	<b>238</b>
2.1	Interface description . . . . .	237	5	<b>Power optimization . . . . .</b>	<b>239</b>
2.1.1	Clock Signals . . . . .	237			

**Chapter 13: LPC315x Clock Generation Unit (CGU)**

1	<b>How to read this chapter . . . . .</b>	<b>240</b>	6.1	Clock switch box . . . . .	285
2	<b>Introduction . . . . .</b>	<b>240</b>	6.1.1	Overview Switchbox Module . . . . .	285
2.1	Features . . . . .	240	6.1.2	Selection stage . . . . .	285
3	<b>General description . . . . .</b>	<b>241</b>	6.1.3	Spreading stage . . . . .	287
3.1	Interface description . . . . .	243	6.1.4	Fractional dividers . . . . .	287
3.1.1	Clock signals . . . . .	243		Example calculation of modula add (madd) and modula subtract (msub) values: . . . . .	287
3.1.2	Interrupt request signals of CGU . . . . .	248	6.1.5	Dynamic fractional dividers . . . . .	288
3.1.3	DMA transfer signals of CGU . . . . .	248	6.1.6	External enabling . . . . .	289
3.1.4	Reset signals of the CGU . . . . .	248	6.1.7	Wake_up feature . . . . .	290
4	<b>Register overview . . . . .</b>	<b>248</b>	6.2	Configuration register block . . . . .	290
4.1	Register overview of clock switchbox . . . . .	248	6.2.1	Watchdog identification register . . . . .	290
4.2	Register overview of the CGU configuration registers . . . . .	259	6.2.2	Controlling the frequency sources . . . . .	290
5	<b>Register description . . . . .</b>	<b>262</b>	6.2.3	Programming PLLs . . . . .	290
5.1	Clock switchbox registers . . . . .	262	6.3	Reset and power block . . . . .	290
5.2	Configuration registers . . . . .	271	6.3.1	Clock disabling . . . . .	291
5.2.1	Power and oscillator control registers . . . . .	271	6.3.2	AHB Master disabling feature . . . . .	291
5.2.2	Reset control registers . . . . .	271	6.4	12 MHz oscillator . . . . .	292
5.2.3	PLL control registers . . . . .	279	6.4.1	Oscillation mode . . . . .	292
6	<b>Functional description . . . . .</b>	<b>284</b>	6.5	PLLs for generating audio clocks and system clocks (HPPLL0 and HPPLL1) . . . . .	293
			6.5.1	Functional description of the PLL . . . . .	293

6.5.2	Use of PLL operating modes . . . . .	294	6.5.2.10	Mode 6: Test mode for digital part . . . . .	296
6.5.2.1	Normal Mode . . . . .	294	6.5.2.11	Mode 7: Enable mode . . . . .	296
6.5.2.2	Mode 1a: Normal operating mode without post-divider and without pre-divider . . . . .	294	6.5.3	Settings for Audio PLL . . . . .	296
6.5.2.3	Mode 1b: Normal operating mode with post-divider and without pre-divider . . . . .	295	6.5.4	Settings for System PLL . . . . .	296
6.5.2.4	Mode 1c: Normal operating mode without post-divider and with pre-divider . . . . .	295	6.6	Typical performance settings . . . . .	298
6.5.2.5	Mode 1d: Normal operating mode with post-divider and with pre-divider . . . . .	295	<b>7</b>	<b>Power optimization . . . . .</b>	<b>300</b>
6.5.2.6	Mode 2: Reserved . . . . .	295	<b>8</b>	<b>Programming guide . . . . .</b>	<b>300</b>
6.5.2.7	Mode 3: Power down mode (pd) . . . . .	295	8.1	Maximum frequencies . . . . .	300
6.5.2.8	Mode 4: Bypass mode . . . . .	295	8.2	Changing fractional dividers values . . . . .	300
6.5.2.9	Mode 5: Reserved . . . . .	296	8.3	Programming variable clock-scaling . . . . .	301
			8.3.1	Programming order variable clock-scaling . . . . .	301
			8.3.2	Programming example for variable clock-scaling . . . . .	302

**Chapter 14: LPC315x WatchDog Timer (WDT)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>304</b>	2.3	Reset signals . . . . .	304
1.1	Features . . . . .	304	<b>3</b>	<b>Register overview . . . . .</b>	<b>305</b>
<b>2</b>	<b>General description . . . . .</b>	<b>304</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>306</b>
2.1	Clock signals . . . . .	304	<b>5</b>	<b>Functional description . . . . .</b>	<b>308</b>
2.2	Interrupt requests . . . . .	304			

**Chapter 15: LPC315x Input/Output configuration modules GPIO/IOCONFIG**

<b>1</b>	<b>Introduction . . . . .</b>	<b>310</b>	<b>3</b>	<b>Register overview . . . . .</b>	<b>311</b>
1.1	Features . . . . .	310	<b>4</b>	<b>Register description . . . . .</b>	<b>312</b>
<b>2</b>	<b>General description . . . . .</b>	<b>310</b>	<b>5</b>	<b>Functional description . . . . .</b>	<b>317</b>
2.1	Interface description . . . . .	311	<b>6</b>	<b>Programming guide . . . . .</b>	<b>318</b>
2.1.1	Clock signals . . . . .	311			
2.1.2	Reset signals . . . . .	311			

**Chapter 16: LPC315x 10-bit Analog-to-Digital Converter (ADC)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>319</b>	4.4	ADC interrupt enable register . . . . .	322
1.1	Features . . . . .	319	4.5	ADC interrupt status register . . . . .	322
<b>2</b>	<b>General description . . . . .</b>	<b>319</b>	4.6	ADC interrupt clear register . . . . .	322
2.1	Interface description . . . . .	319	<b>5</b>	<b>Functional description . . . . .</b>	<b>323</b>
2.1.1	Clock Signals . . . . .	319	5.1	A/D conversion control . . . . .	323
2.1.2	Pin connections . . . . .	320	5.2	ADC Resolution . . . . .	323
2.1.3	Reset signals . . . . .	320	5.3	Multi-channel A/D conversion scan . . . . .	323
<b>3</b>	<b>Register overview . . . . .</b>	<b>320</b>	5.4	Clocking . . . . .	323
<b>4</b>	<b>Register description . . . . .</b>	<b>320</b>	5.5	Interrupts . . . . .	324
4.1	ADC data registers . . . . .	320	<b>6</b>	<b>Power optimization . . . . .</b>	<b>324</b>
4.2	ADC control register . . . . .	321	<b>7</b>	<b>Programming guide . . . . .</b>	<b>324</b>
4.3	ADC channel selection register . . . . .	321			

**Chapter 17: LPC315x event router**

<b>1</b>	<b>Introduction . . . . .</b>	<b>326</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>333</b>
1.1	Features . . . . .	326	4.1	Pending Register pend[0] to pend[3] . . . . .	333
<b>2</b>	<b>General description . . . . .</b>	<b>326</b>	4.2	Interrupt Clear Register int_clr[0] to int_clr[3] . . . . .	336
2.1	Interface description . . . . .	327	4.3	Interrupt set register int_set[0] to int_set[3] . . . . .	337
2.1.1	Clock signals . . . . .	327	4.4	Mask Register mask[0] to mask[3] . . . . .	337
2.1.2	Pin connections . . . . .	327	4.5	Mask clear register mask_clr[0] to mask_clr[3] . . . . .	337
2.1.3	Interrupt request signals . . . . .	329	4.6	Mask set register mask_set[0] to mask_set[3] . . . . .	337
2.1.4	Reset signals . . . . .	329			
<b>3</b>	<b>Register overview . . . . .</b>	<b>330</b>			

4.7	Activation polarity register apr[0] to apr[3] . . .	338	4.13	Interrupt output mask clear register intoutMaskClr[0:4][0:3] . . . . .	340
4.8	Activation type register atr[0] to atr[3]. . . . .	338	4.14	Interrupt output mask set register intoutMaskSet[0:4][0:3] . . . . .	340
4.9	Raw status registers rsr[0] to rsr[3]. . . . .	339	<b>5</b>	<b>Functional description . . . . .</b>	<b>341</b>
4.10	Intout register . . . . .	339	5.1	Wake-up Behavior . . . . .	341
4.11	Interrupt output pending register intoutPend[0:4][0:3] . . . . .	339	5.2	Architecture . . . . .	341
4.12	Interrupt output mask register intoutMask[0:4][0:3] . . . . .	340	<b>6</b>	<b>Power optimization . . . . .</b>	<b>342</b>

**Chapter 18: LPC315x Random Number Generator (RNG)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>343</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>344</b>
<b>2</b>	<b>General description . . . . .</b>	<b>343</b>	<b>5</b>	<b>Functional description . . . . .</b>	<b>345</b>
2.1	Features . . . . .	343	<b>6</b>	<b>Power optimization . . . . .</b>	<b>345</b>
2.2	Interface description . . . . .	343	<b>7</b>	<b>Programming guide . . . . .</b>	<b>346</b>
2.2.1	Clock signals . . . . .	343	7.1	Enabling the RNG . . . . .	346
2.2.2	Interrupt request signals . . . . .	344	7.2	Reading a random number from the RNG . .	346
2.2.3	Reset signals . . . . .	344	7.3	Disable the RNG . . . . .	346
<b>3</b>	<b>Register overview . . . . .</b>	<b>344</b>			

**Chapter 19: LPC315x One-Time Programmable memory (OTP)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>347</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>349</b>
1.1	Features . . . . .	347	4.1	Control registers . . . . .	349
<b>2</b>	<b>General description . . . . .</b>	<b>347</b>	4.2	Data registers . . . . .	350
2.1	Block diagram . . . . .	347	<b>5</b>	<b>Functional description . . . . .</b>	<b>351</b>
2.2	Electrical specification . . . . .	348	<b>6</b>	<b>Power optimization . . . . .</b>	<b>351</b>
2.3	Interface description . . . . .	348	<b>7</b>	<b>Programming guide . . . . .</b>	<b>351</b>
2.3.1	Clock signals . . . . .	348	7.1	Production line use case . . . . .	351
2.3.2	Pin connections . . . . .	348	7.2	Application use case . . . . .	352
2.3.3	Reset signals . . . . .	348	7.3	OTP fuse map . . . . .	354
<b>3</b>	<b>Register overview . . . . .</b>	<b>349</b>			

**Chapter 20: LPC315x SPI**

<b>1</b>	<b>Introduction . . . . .</b>	<b>355</b>	4.1	SPI configuration registers . . . . .	359
1.1	Features . . . . .	355	4.2	SPI slave registers . . . . .	364
<b>2</b>	<b>General description . . . . .</b>	<b>355</b>	4.3	SPI interrupt registers . . . . .	365
2.1	Interface description . . . . .	356	<b>5</b>	<b>Functional description . . . . .</b>	<b>367</b>
2.1.1	Clock signals . . . . .	356	5.1	Formats . . . . .	368
2.1.2	Bus interface . . . . .	356	5.1.1	SSI Format . . . . .	369
2.1.3	Pin connections . . . . .	356	5.1.2	SPI Format . . . . .	370
2.1.4	Interrupt request signals . . . . .	357	5.2	Operation Modes . . . . .	374
2.1.5	Reset signals . . . . .	357	5.2.1	Sequential Multi-Slave Mode . . . . .	374
2.1.6	DMA transfer signals . . . . .	357	5.2.2	Normal Transmission Mode . . . . .	377
<b>3</b>	<b>Register overview . . . . .</b>	<b>357</b>	5.2.3	Slave Mode . . . . .	377
<b>4</b>	<b>Register description . . . . .</b>	<b>359</b>	<b>6</b>	<b>Power optimization . . . . .</b>	<b>378</b>
			<b>7</b>	<b>Programming guide . . . . .</b>	<b>378</b>

**Chapter 21: LPC315x Memory Card Interface (MCI)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>379</b>	2.2.2	Bus interface . . . . .	381
1.1	Features . . . . .	379	2.2.3	Pin connections . . . . .	381
<b>2</b>	<b>General description . . . . .</b>	<b>379</b>	2.2.4	Interrupt request signals . . . . .	382
2.1	Block diagram . . . . .	379	2.2.5	Reset signals . . . . .	382
2.2	Interface description . . . . .	380	2.2.6	DMA transfer signals . . . . .	382
2.2.1	Clock signals . . . . .	380	2.2.7	System control register (SysCReg) signals .	382
			<b>3</b>	<b>Register overview . . . . .</b>	<b>383</b>

<b>4</b>	<b>Register description</b> .....	<b>384</b>	7.2.9	Stream Write .....	409
<b>5</b>	<b>Functional description</b> .....	<b>398</b>	7.2.10	Sending Stop or Abort in Middle of Transfer	409
5.1	Auto-Stop .....	398	7.3	Suspend or Resume Sequence .....	410
<b>6</b>	<b>Power optimization</b> .....	<b>400</b>	7.3.1	Read_Wait Sequence .....	412
<b>7</b>	<b>Programming guide</b> .....	<b>400</b>	7.3.2	CE-ATA Data Transfer Commands .....	412
7.1	Software/hardware restrictions .....	400	7.3.2.1	Reset and Device Recovery .....	412
7.2	Programming sequence .....	402	7.3.2.2	ATA Task File Transfer .....	413
7.2.1	Initialization .....	402	7.3.2.3	ATA Payload Transfer Using RW_MULTIPLE_BLOCK (RW_BLK) .....	414
7.2.2	Enumerated Card Stack .....	402	7.3.2.4	Sending Command Completion Signal Disable .....	416
7.2.3	Clock Programming .....	403	7.3.2.5	Recovery after Command Completion Signal Timeout .....	416
7.2.4	No-Data Command With or Without Response Sequence .....	404	7.3.2.6	Reduced ATA Command Set .....	416
7.2.5	Data Transfer Commands .....	405	7.3.3	Controller/DMA/FIFO Reset Usage .....	418
7.2.6	Single-Block or Multiple-Block Read .....	406	7.3.4	Error Handling .....	419
7.2.7	Single-Block or Multiple-Block Write .....	407			
7.2.8	Stream Read .....	409			

**Chapter 22: LPC315x Universal Asynchronous Receiver/Transmitter (UART)**

<b>1</b>	<b>Introduction</b> .....	<b>421</b>	4.10	LSR (Line Status Register) .....	431
1.1	Features .....	421	4.11	MSR (Modem Status Register) .....	433
<b>2</b>	<b>General description</b> .....	<b>421</b>	4.12	SCR (Scratch Register) .....	433
2.1	About UART .....	421	4.13	ICR (IrDA Control Register) .....	433
2.2	About IrDA .....	422	4.14	FDR (Fractional Divider Register) .....	434
2.3	Block diagram .....	422	4.15	NHP POP Register .....	435
2.4	Interface description .....	423	4.16	Mode Selection Register .....	435
2.4.1	Clock signals .....	423	4.17	INTCE (Interrupt Clear Enable Register) ...	435
2.4.2	Pin connections .....	423	4.18	INTSE (Interrupt Set Enable Register) .....	436
2.4.3	Interrupt Request Signals .....	424	4.19	INTS (Interrupt Status Register) .....	437
2.4.4	Reset Signals .....	424	4.20	INTE (Interrupt Enable Register) .....	437
2.4.5	DMA Transfer Signals .....	424	4.21	INTCS (Interrupt Clear Status Register) ...	438
<b>3</b>	<b>Register overview</b> .....	<b>424</b>	4.22	INTSS (Interrupt Set Status Register) .....	438
<b>4</b>	<b>Register description</b> .....	<b>425</b>	<b>5</b>	<b>Functional Description</b> .....	<b>439</b>
4.1	Receive Buffer Register .....	425	5.1	Serial Interface .....	439
4.2	Transmitter Holding Register (THR) .....	425	5.2	Basic receive and transmit .....	439
4.3	Divisor Latch register LSB (DLL) .....	426	5.3	Loop-back mode .....	440
4.4	Divisor latch register MSB .....	426	5.4	Break mode .....	441
4.5	Interrupt Enable Register (IER) .....	427	5.5	Baud-rate generation .....	441
4.6	Interrupt Identification Register (IIR) .....	427	5.5.1	Algorithm to determine fractional divider settings .....	443
4.7	FIFO Control Register (FCR) .....	429	5.5.1.1	Baud rate calculation .....	444
4.8	Line Control Register (LCR) .....	429	<b>6</b>	<b>Power optimization</b> .....	<b>447</b>
4.9	MCR (Modem Control Register) .....	431			

**Chapter 23: LPC315x LCD interface**

<b>1</b>	<b>Introduction</b> .....	<b>448</b>	4.2	LCD interface Control register .....	452
<b>2</b>	<b>General description</b> .....	<b>448</b>	4.3	LCD interface Interrupt raw register .....	454
2.1	Block diagram .....	449	4.4	LCD interface Interrupt Clear register .....	454
2.2	Interface description .....	449	4.5	LCD interface Interrupt Mask register .....	455
2.2.1	Clock signals .....	449	4.6	LCD interface Read Command register .....	455
2.2.2	External pin connections .....	449	4.7	LCD interface Instruction Byte register .....	455
2.2.3	Interrupt request signals .....	450	4.8	LCD interface Data Byte register .....	456
2.2.4	Reset signals .....	450	4.9	LCD interface Instruction Word register .....	456
2.2.5	LCD timing .....	451	4.10	LCD interface Data Word register .....	456
<b>3</b>	<b>Register overview</b> .....	<b>452</b>	<b>5</b>	<b>Functional description</b> .....	<b>456</b>
<b>4</b>	<b>Register description</b> .....	<b>452</b>	5.1	Interrupt generation .....	456
4.1	LCD interface Status Register .....	452	5.2	Clearing the interrupts .....	457

5.3	Using DMA flow control . . . . .	457	LCD_DATA_BYTE / LCD_DATA_WORD . . .	459
<b>6</b>	<b>Power optimization . . . . .</b>	<b>457</b>	7.5 Reading data . . . . .	459
<b>7</b>	<b>Programming guide . . . . .</b>	<b>457</b>	7.6 Combined Writing and reading data. . . . .	460
7.1	Resetting the external LCD controller. . . . .	457	7.7 Using wait states . . . . .	460
7.2	FIFO . . . . .	458	7.8 Serial mode . . . . .	460
7.3	Operational modes . . . . .	458	7.8.1 Serial writes . . . . .	460
7.3.1	16-bit mode. . . . .	458	7.8.2 Serial reads . . . . .	461
7.3.2	8-bit mode. . . . .	458	7.8.3 Serial clock timing . . . . .	461
7.3.3	4-bit mode. . . . .	458	7.9 Checking the busy flag of the LCD controller	461
7.3.4	Serial mode . . . . .	459	7.10 Loop back mode . . . . .	462
7.4	Writing data. . . . .	459	7.11 Clock relation PCLK and LCDCLK. . . . .	462
	LCD_INST_BYTE/LCD_INST_WORD. . . . .	459	7.12 MSB_FIRST bit of Control Register. . . . .	463

**Chapter 24: LPC315x I<sup>2</sup>C-bus interface**

<b>1</b>	<b>Introduction . . . . .</b>	<b>464</b>	4.8 I2Cn Receive FIFO level register. . . . .	474
1.1	Features . . . . .	464	4.9 I2Cn Transmit FIFO level register . . . . .	474
<b>2</b>	<b>General description . . . . .</b>	<b>464</b>	4.10 I2Cn Receive byte count register. . . . .	474
2.1	Block diagram. . . . .	465	4.11 I2Cn Transmit Byte count register . . . . .	475
2.2	Interface description . . . . .	466	4.12 I2Cn Slave Transmit FIFO register . . . . .	475
2.2.1	Clock signals . . . . .	466	4.13 I2Cn Slave Transmit FIFO level register . . .	475
2.2.2	Pin connections . . . . .	466	<b>5</b>	<b>Functional description . . . . .</b>
2.2.3	Interrupt requests . . . . .	467	5.1	Overview . . . . .
2.2.4	Reset signals . . . . .	467	5.2	I <sup>2</sup> C clock settings . . . . .
2.2.5	DMA flow control transfer signals . . . . .	467	5.3	I <sup>2</sup> C Data . . . . .
<b>3</b>	<b>Register overview . . . . .</b>	<b>467</b>	5.4	Start Condition . . . . .
<b>4</b>	<b>Register description . . . . .</b>	<b>468</b>	5.5	Stop Condition . . . . .
4.1	I2Cn RX Data FIFO register . . . . .	468	5.6	Acknowledge . . . . .
4.2	I2Cn TX Data FIFO register . . . . .	468	5.7	I <sup>2</sup> C Addresses . . . . .
4.3	I2Cn Status register . . . . .	469	5.8	I <sup>2</sup> C Write. . . . .
4.4	I2Cn Control register . . . . .	471	5.9	I <sup>2</sup> C Read . . . . .
4.5	I2Cn Clock Divider High register. . . . .	473	5.10	I <sup>2</sup> C Write/Read . . . . .
4.6	I2Cn Clock Divider Low register . . . . .	473	5.11	Bus Arbitration . . . . .
4.7	I2Cn Slave Address register. . . . .	474	5.12	Clock Synchronization . . . . .

**Chapter 25: LPC315x Timer 0/1/2/3**

<b>1</b>	<b>Introduction . . . . .</b>	<b>483</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>484</b>
1.1	Features . . . . .	483	4.1	Timer Load register . . . . .	484
<b>2</b>	<b>General description . . . . .</b>	<b>483</b>	4.2	Timer Value register. . . . .	484
2.1	Clock signals . . . . .	483	4.3	Timer Control register . . . . .	484
2.2	Interface description . . . . .	483	4.4	Timer Clear register . . . . .	485
2.2.1	Interrupt Requests . . . . .	483	<b>5</b>	<b>Functional description . . . . .</b>	<b>485</b>
2.2.2	Reset Signals . . . . .	483	<b>6</b>	<b>Power optimization . . . . .</b>	<b>487</b>
<b>3</b>	<b>Register overview . . . . .</b>	<b>484</b>	<b>7</b>	<b>Programming guide . . . . .</b>	<b>487</b>

**Chapter 26: LPC315x Pulse Width Modulator (PWM)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>488</b>	2.1.3	Reset signals . . . . .	489
1.1	Features . . . . .	488	<b>3</b>	<b>Register overview . . . . .</b>	<b>489</b>
<b>2</b>	<b>General description . . . . .</b>	<b>488</b>	<b>4</b>	<b>Register description . . . . .</b>	<b>489</b>
2.1	Interface description . . . . .	489	<b>5</b>	<b>Functional description . . . . .</b>	<b>490</b>
2.1.1	Clock signals . . . . .	489	<b>6</b>	<b>Programming guide . . . . .</b>	<b>490</b>
2.1.2	Pin connections . . . . .	489			

**Chapter 27: LPC315x System control (SysCReg)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>491</b>	1.1	Features . . . . .	491
----------	-------------------------------	------------	-----	--------------------	-----

<b>2</b>	<b>Interface description</b> . . . . .	<b>491</b>	4.4	ISRAM configuration registers . . . . .	502
2.1	Clock signals . . . . .	491	4.5	ISROM configuration registers . . . . .	503
2.2	Reset signals . . . . .	491	4.6	MPMC configuration registers . . . . .	503
<b>3</b>	<b>Register overview</b> . . . . .	<b>492</b>	4.6.1	Static memory chip and address select modes . . . . .	503
<b>4</b>	<b>Register description</b> . . . . .	<b>497</b>	4.6.2	Dynamic memory delay modes . . . . .	505
4.1	Miscellaneous system control registers, part 1 . . . . .	497	4.6.3	MPMC CS1 memory width register . . . . .	506
4.1.1	EBI timeout registers . . . . .	497	4.6.4	MPMC testmode registers . . . . .	507
4.1.2	Ring oscillator enable register . . . . .	498	4.7	Miscellaneous system configuration registers, part2 . . . . .	508
4.1.3	ADC power-down register . . . . .	498	4.7.1	AHB external priority settings . . . . .	508
4.1.4	AHB master configuration register . . . . .	498	4.7.2	Shadow memory control register . . . . .	508
4.2	SD/MMC configuration registers . . . . .	500	4.8	Pin multiplexing registers . . . . .	509
4.3	USB registers . . . . .	500	4.9	Pad configuration registers . . . . .	511
4.3.1	USB PLL configuration registers . . . . .	501			

**Chapter 28: LPC315x Pulse Code Modulation (PCM)/ISDN Oriented Modular (IOM) interface**

<b>1</b>	<b>Introduction</b> . . . . .	<b>513</b>	<b>4</b>	<b>Register description</b> . . . . .	<b>515</b>
1.1	Features . . . . .	513	<b>5</b>	<b>Functional description</b> . . . . .	<b>518</b>
<b>2</b>	<b>General description</b> . . . . .	<b>513</b>	5.1	Architecture . . . . .	518
2.1	Interface description . . . . .	513	5.2	Operation . . . . .	519
2.1.1	Clock signals . . . . .	513	5.3	PAD Configuration . . . . .	521
2.1.2	Pin connections . . . . .	514	5.4	Bi-directional data line configuration . . . . .	521
2.1.3	Interrupt requests . . . . .	514	5.5	Timing . . . . .	523
2.1.4	Reset signals . . . . .	514	5.6	Timing controller . . . . .	526
2.1.5	DMA transfer signals . . . . .	514	<b>6</b>	<b>Power optimization</b> . . . . .	<b>526</b>
<b>3</b>	<b>Register overview</b> . . . . .	<b>515</b>			

**Chapter 29: LPC315x I2S interface**

<b>1</b>	<b>Introduction</b> . . . . .	<b>527</b>	2.1.5	DMA transfer signals . . . . .	530
1.1	Features . . . . .	527	<b>3</b>	<b>Register overview</b> . . . . .	<b>531</b>
<b>2</b>	<b>General description</b> . . . . .	<b>527</b>	<b>4</b>	<b>Register descriptions</b> . . . . .	<b>532</b>
2.1	Interface description . . . . .	528	<b>5</b>	<b>Functional description</b> . . . . .	<b>533</b>
2.1.1	Clock signals . . . . .	528	<b>6</b>	<b>Power optimization</b> . . . . .	<b>534</b>
2.1.2	Pin connections . . . . .	529	<b>7</b>	<b>Programming guide</b> . . . . .	<b>534</b>
2.1.3	Interrupt requests . . . . .	529			
2.1.4	Reset signals . . . . .	530			

**Chapter 30: LPC315x Analog die overview**

<b>1</b>	<b>Introduction</b> . . . . .	<b>536</b>	4.1.2	PSU and Li-ion charger status register (DCDCLIC) . . . . .	545
<b>2</b>	<b>General description</b> . . . . .	<b>537</b>	4.1.3	Analog die CGU control register (CGU_ANALOG) . . . . .	546
2.1	Interface description . . . . .	537	4.2	Audio codec registers . . . . .	548
2.1.1	Clock signals . . . . .	537	4.2.1	Analog input PGA control register . . . . .	548
2.2	Pin connections . . . . .	539	4.2.2	Analog input control register (AIN_1) . . . . .	549
2.2.1	External pins . . . . .	539	4.2.3	Analog output control register AOUT . . . . .	550
2.2.2	Internal pins . . . . .	540	4.2.4	Decimator control register (DEC) . . . . .	551
<b>3</b>	<b>Register overview</b> . . . . .	<b>541</b>	4.2.5	Interpolator control register INT0 . . . . .	553
3.1	Register access . . . . .	542	4.2.6	Interpolator volume control register INT1 . . . . .	554
3.1.1	Write cycle . . . . .	542	4.3	I2S1 digital audio multiplexer control register I2S1MUX . . . . .	554
3.1.2	Read cycle . . . . .	543	4.4	Analog out status register (AOUTDECINT) . . . . .	555
<b>4</b>	<b>Register description</b> . . . . .	<b>543</b>	4.5	RTC registers . . . . .	556
4.1	Li-ion charger and PSU registers . . . . .	543	4.5.1	RTC time shadow register (RTC_TIME) . . . . .	556
4.1.1	PSU and Li-ion charger control register OTGDCLIC . . . . .	543	4.5.2	RTC alarm register (RTC_ALARM) . . . . .	557

4.5.3	RTC status register (RTC_STATUS) . . . . .	557	4.5.5	RTC clear enable status register (RTC_CLR_ENA_STAT) . . . . .	558
4.5.4	RTC set enable and status register (RTC_SET_ENA_STAT). . . . .	557			

**Chapter 31: LPC315x Analog audio codec**

<b>1</b>	<b>Introduction . . . . .</b>	<b>559</b>	3.5.7	Applications with higher voltage input . . . . .	565
<b>2</b>	<b>General description . . . . .</b>	<b>560</b>	3.5.8	Low Noise Amplifier (LNA). . . . .	566
2.1	Block diagram . . . . .	560	3.5.9	MUX . . . . .	566
<b>3</b>	<b>Analog input . . . . .</b>	<b>560</b>	3.6	Power optimization. . . . .	567
3.1	Introduction . . . . .	560	<b>4</b>	<b>Analog output . . . . .</b>	<b>567</b>
3.1.1	Features . . . . .	561	4.1	General description . . . . .	567
3.2	General description . . . . .	561	4.2	Pin connections . . . . .	568
3.2.1	Block diagram . . . . .	561	4.3	Register overview . . . . .	568
3.3	Interface description . . . . .	562	4.4	Analog audio path . . . . .	568
3.3.1	Clock signals . . . . .	562	4.4.1	Power-up sequence . . . . .	569
3.3.2	ADC clocking . . . . .	562	4.4.2	Volume settings . . . . .	569
3.3.3	Pin connections . . . . .	562	4.4.3	Power-down sequence . . . . .	569
3.4	Register overview . . . . .	562	4.5	Decimator/AGC function . . . . .	570
3.5	Functional description. . . . .	563	4.6	Digital audio path . . . . .	570
3.5.1	ADC analog front-end. . . . .	563	4.6.1	Power-up sequence . . . . .	570
3.5.2	Functional and Power-down modes . . . . .	563	4.6.2	D/A converter settings . . . . .	571
3.5.3	Stereo Analog to Digital Converter (SADC) . . . . .	563	4.6.3	Power-down sequence . . . . .	571
3.5.4	Single-to-Differential Converter (SDC) . . . . .	564	4.7	Headphone amplifier . . . . .	571
3.5.5	Bias block . . . . .	564	4.8	Slow reference buffer . . . . .	572
3.5.6	Programmable Gain Amplifier (PGA) . . . . .	564	<b>5</b>	<b>Power optimization . . . . .</b>	<b>572</b>

**Chapter 32: LPC315x Power Supply Unit (PSU)**

<b>1</b>	<b>Introduction . . . . .</b>	<b>573</b>	<b>5</b>	<b>Functional description . . . . .</b>	<b>575</b>
<b>2</b>	<b>General description . . . . .</b>	<b>573</b>	5.1	Switching conversion . . . . .	575
2.1	Block diagram . . . . .	574	5.2	Control of the switching PSU . . . . .	577
2.2	Pin connections . . . . .	574	5.2.1	Analog part of the controller. . . . .	580
<b>3</b>	<b>Register overview . . . . .</b>	<b>575</b>	5.3	Linear voltage regulator . . . . .	581
<b>4</b>	<b>Register description . . . . .</b>	<b>575</b>	5.4	Use of an external (off-chip) PSU . . . . .	582

**Chapter 33: LPC315x Li-ion charger**

<b>1</b>	<b>Introduction . . . . .</b>	<b>583</b>	<b>4</b>	<b>Register overview . . . . .</b>	<b>586</b>
<b>2</b>	<b>Battery charging aspects . . . . .</b>	<b>583</b>	<b>5</b>	<b>Functional description . . . . .</b>	<b>586</b>
<b>3</b>	<b>General description . . . . .</b>	<b>585</b>	5.1	Battery current setting . . . . .	586
3.1	Interface description . . . . .	585	5.2	Battery voltage sensing . . . . .	587
3.1.1	Clock signal . . . . .	585	5.3	VNTC sensing for guarding the battery temperature . . . . .	587
3.1.2	Pin connections . . . . .	585			

**Chapter 34: LPC315x RTC**

<b>1</b>	<b>Introduction . . . . .</b>	<b>588</b>	5.3	Global function . . . . .	590
1.1	Features . . . . .	588	5.4	Power-down and internal reset . . . . .	590
<b>2</b>	<b>General description . . . . .</b>	<b>588</b>	5.5	RTC driver . . . . .	591
2.1	Block diagram . . . . .	588	5.5.1	Boot driver . . . . .	591
2.2	Pin connections . . . . .	588	5.5.2	Time driver . . . . .	592
<b>3</b>	<b>Register overview . . . . .</b>	<b>589</b>	<b>6</b>	<b>Hardware interface . . . . .</b>	<b>593</b>
<b>4</b>	<b>Register description . . . . .</b>	<b>589</b>	6.1	Power . . . . .	593
<b>5</b>	<b>Functional description . . . . .</b>	<b>589</b>	6.2	Reset . . . . .	593
5.1	Initialization of the RTC. . . . .	589	6.3	Clocking . . . . .	593
5.2	Epoch . . . . .	589	6.4	Open-drain interrupt. . . . .	594

**Chapter 35: LPC315x USB Charge pump**

<b>1</b>	<b>Introduction</b> .....	<b>595</b>	<b>4</b>	<b>Functional description</b> .....	<b>596</b>
1.1	Features .....	595	4.1	Basic functions .....	596
<b>2</b>	<b>General description</b> .....	<b>595</b>	4.2	Modes of operation .....	597
2.1	Interface description .....	595	<b>5</b>	<b>Application schematic</b> .....	<b>597</b>
2.1.1	Clock signal .....	595	5.1	USB OTG supply (used) .....	597
2.1.2	Pin connections .....	595	5.2	USB OTG supply (not used) .....	598
<b>3</b>	<b>Register overview</b> .....	<b>596</b>			

**Chapter 36: LPC315x JTAG**

<b>1</b>	<b>Introduction</b> .....	<b>599</b>	2.1	External pin connections .....	600
1.1	Features .....	599	2.2	JTAG considerations .....	601
<b>2</b>	<b>General description</b> .....	<b>599</b>	2.3	JTAG support circuit design .....	601
			2.4	Tool consideration .....	602

**Chapter 37: LPC315x Pin configuration and I/O muxing**

<b>1</b>	<b>Introduction</b> .....	<b>603</b>	<b>3</b>	<b>LCD/NAND flash/SDRAM multiplexing</b> ....	<b>613</b>
<b>2</b>	<b>Pinning information</b> .....	<b>603</b>	3.1	Multiplexing between LCD and MPMC ....	615
			3.2	Supply domains .....	616
