Chapter 1 Introduction

The Kinetis software development kit (KSDK) is an extensive suite of robust hardware interface and hardware abstraction layers, peripheral drivers, RTOS abstractions, stacks, and middleware designed to simplify and accelerate application development on Freescale Kinetis MCUs. The addition of Processor Expert technology for software and board configuration provides unmatched ease of use and flexibility.

Included in the Kinetis SDK is full source code under a permissive open-source license for all hardware abstraction and peripheral driver software. Mainline releases include support for a collection of Kinetis MCUs, whereas standalone releases offer support for one or a few additional Kinetis MCUs only. See the Release Notes and the Supported Devices section on www.freescale.com/ksdk for details.

The Kinetis SDK consists of the following runtime software components written in C:

- ARM[®] CMSIS Core and DSP standard libraries and CMSIS-compliant device header files which provide direct access to the peripheral registers and bits
- An open-source hardware abstraction layer (HAL) that provides a simple, stateless driver with an API encapsulating the low-level functions of the peripheral
- System services for centralized resources including a clock manager, interrupt manager, low-power manager, and a hardware timer
- Open-source, high-level peripheral drivers that build upon the HAL layer and may utilize one or more of the system services; drivers may be used as-is or as a reference for creating custom drivers
- An operating system abstraction (OSA) layer for adapting applications for use with a real time operating system (RTOS) or bare metal (no RTOS) applications. OSAs are provided for:
 - Freescale MQX[™] RTOS

- FreeRTOS
- Micrium uC/OS-II
- Micrium uC/OS-III
- bare-metal (no RTOS)
- Stacks and middleware in source or object formats including:
 - a USB device, host, and OTG stack with comprehensive USB class support
 - CMSIS-DSP, a suite of common signal processing functions
 - FatFs, a FAT file system for small embedded systems
 - Encryption software utilizing the mmCAU hardware acceleration unit

The Kinetis SDK comes complete with software examples demonstrating the usage of the hardware abstraction layer, peripheral drivers, middleware, and RTOSes. All examples are provided with projects for the following toolchains:

- Atollic TrueSTUDIO
- GNU toolchain for ARM[®] Cortex[®] -M with Cmake build system
- IAR Embedded Workbench
- Keil MDK
- Kinetis Design Studio
- lwIP, a lightweight TCPIP networking stack

The HAL, peripheral drivers and system services can be used across multiple devices within the Kinetis product family without code modification. The configurable items for each driver, at all levels, are encapsulated into C language data structures. Kinetis devices specific configuration information is provided as part of the KSDK and need not be modified by the user. HAL, peripheral driver, and system services configuration is not fixed and can be changed at runtime. Optionally, the entire driver set can be pre-built into a library.

The example applications demonstrate how to configure the drivers by passing configuration data to the APIs. In addition to the software source, Processor Expert is provided as a time-saving option for software and board configuration. Processor Expert is a complimentary PC-hosted software configuration tool (Eclipse plug-in) with complete knowledge of all Kinetis MCUs. It provides a graphical user interface to handle MCU-specific board configuration and driver tuning tasks including:

- Optional generation of low-level device initialization code for post-reset configuration
- Package I/O allocation and pin initialization source code generation
- Creation and management of HAL and peripheral driver C source configuration data structures

The organization of files in the Kinetis SDK release package is focused on ease-of-use. The Kinetis SDK folder hierarchy is organized at the top level with these folders:

| Deliverable | Location |
|---|---|
| Examples | <install_dir>/examples/... |
| Demo applications | <install_dir>/examples/<board_name>/demo_apps/... |
| Driver examples | <install_dir>/examples/<board_name>/driver_examples/... |
| Documentation | <install_dir>/doc/... |
| MQX Documentation | <install_dir>/doc/rtos/mqx/... |
| USB Documentation | <install_dir>/doc/usb/... |
| MQX RTCS Documentation | <install_dir>/doc/tcpip/mqx_rtcs/... |
| LWIP Documentation | <install_dir>/doc/tcpip/lwip/... |
| MQX MFS Documentation | <install_dir>/doc/filesystem/mqx_mfs/... |
| Projects to build libraries | <install_dir>/lib/... |
| Middleware | <install_dir>/middleware/... |
| TCP/IP stacks | <install_dir>/middleware/tcpip/... |
| File System | <install_dir>/middleware/filesystem/... |
| Driver library, startup code and utilities | <install_dir>/platform/... |
| Cortex Microcontroller Software Interface Standard (CMSIS) ARM Cortex-M header files, DSP library source, and IP extension header files | <install_dir>/platform/CMSIS/... |
| Composite drivers for SD-card and Soundcard support | <install_dir>/platform/composite/... |
| Linkercontrol files for each supported tool chain | <install_dir>/platform/devices/<board_name>/linker/... |
| CMSIS compliant Startup Code | <install_dir>/platform/devices/<board_name>/startup/... |
| Peripheral Drivers | <install_dir>/platform/drivers/... |
| Hardware Abstraction Layer | <install_dir>/platform/hal/... |
| OS Abstraction for Bare Metal and RTOS | <install_dir>/platform/osa/... |
| System Services such as clock manager, interrupt manager, unified hardware timer, and low power manager | <install_dir>/platform/system/... |
| Utilities such as debug console | <install_dir>/platform/utilities/... |
| RTOS Kernel Code, RTOS abstraction implementations, and RTOS kernel folders | <install_dir>/rtos/... |
| A Processor Expert service pack and cmake toolchain files. | <install_dir>/tools |
| USB stack | <install_dir>/usb/... |
| Utilities such as shell and standard libraries | <install_dir>/utilities/... |

The rest of the document describes the API references in detail for HAL and Peripheral drivers.

For the latest version of this and other Kinetis SDK documents, see the Kinetis SDK homepage www.freescale.com/ksdk.

Chapter 2 Architectural Overview

This chapter provides the architectural overview for the Kinetis Software Development Kit (KSDK). It describes each layer within the architecture and its associated components.

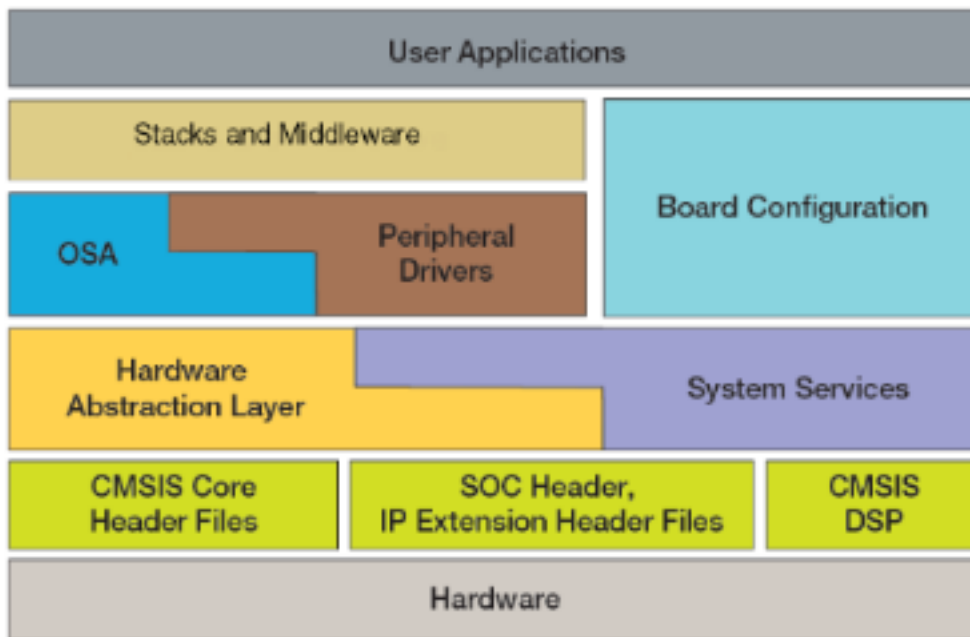

Overview

The KSDK architecture consists of eight key components listed below.

1. The ARM Cortex Microcontroller Software Interface Standard (CMSIS) CORE compliance device specific header files, SOC Header, IP Extension Header Files, and CMSIS DSP libraries.
2. System Services
3. Hardware Abstraction Layer
4. Peripheral Driver Layer
5. Real-time Operating System (RTOS) Abstraction Layer
6. Board-specific configuration
7. Stack and Middleware that integrate with KSDK
8. Applications based on the KSDK architecture

This image shows how each component stacks up.

The Kinetis SDK consists of these runtime software components written in C:

Kinetis MCU header files

The KSDK contains CMSIS-compliant device-specific header files which provide direct access to the Kinetis MCU peripheral registers. Each supported Kinetis MCU device in KSDK has an overall System-

on-Chip (SoC) memory-mapped header file. This header file contains the memory map and register base address for each peripheral and the IRQ vector table with associated vector numbers. The overall SoC header file provides an access to the peripheral registers through pointers and predefined masks.

In addition to the overall SoC memory-mapped header file, the KSDK includes extension header files for each peripheral instantiated on the Kinetis MCU. The extension header files take advantage of the bit band feature when reading from or writing to 1-bit wide fields within a register. Macros are provided in the SoC memory-mapped header files for accessing register bit fields. When accessing the register macros in the extension header file, the user must pass in the register base address for the desired peripheral as a pointer to `<IP>_Type` structure. The KSDK HAL Driver (discussed later) API functions take in the base address and then passes this into the extension header file macros for peripheral register accesses.

Along with the SoC header files and peripheral extension header files, the KSDK also includes common CMSIS header files for the ARM Cortex-M core and DSP library from the latest CMSIS release. The CMSIS DSP library source code is also included for reference. These files and the above mentioned header files can all be found in the KSDK platform/CMSIS directory.

System Services

The KSDK System Services contain a set of software entities that can be used by the Peripheral Drivers. They may be used with HAL Drivers to build the Peripheral Drivers or they can be used by an application directly. The following sections describe each of the System Services software entities. These System Services are in the KSDK platform/system directory.

Interrupt Manager

The Interrupt Manager provides functions to enable and disable individual interrupts within the Nested Vector Interrupt Controller (NVIC). It also provides functions to enable and disable the ARM core global interrupt (via the CPSIE and CPSID instructions) for bare-metal critical section implementation. In addition to providing functions for interrupt enabling and disabling, the Interrupt Manager provides Interrupt Service Routine (ISR) registration that allows the application software to register or replace the interrupt handler for a specified IRQ vector. The KSDK drivers do not set interrupt priorities. The interrupt priority scheme is entirely determined by the specific application logic and its setting is handled by the user application. The user application manages the interrupt priorities by using the NVIC functions provided in the ARM Cortex-M core CMSIS header file.

Clock Manager

The Clock Manager provides centralized clock-related functions for the entire system. It can dynamically set the system clock and perform clock gating/un-gating for specific peripherals. The Clock Manager also maintains knowledge of the clock sources required for each peripheral and provides functions to obtain the clock frequency for each supported clock used by the peripheral. The Clock Manager provides a notification framework which the software component of the KSDK, such as drivers, uses to register callback functions and execute the predefined code flow during the clock mode transition.

Power Manager

The Power Manager provides centralized power-related functions for the entire system. It dynamically sets the system power mode and configures the LLWU wakeup setting. The Clock Manager provides a notification framework which the software component of the KSDK, such as drivers, uses to register callback functions and execute the predefined code flow during the clock mode transition.

Unified Hardware (HW) Timer

The Unified HW Timer provides a common timer interface that can be linked with any supported Kinetis MCU hardware timer peripheral or with the ARM core system timer (SysTick) to perform basic timer operations. It can be used as a shared timer capable of microsecond resolution for bare-metal use-cases, such as to time guard busy loops. It can also be used when interfacing with an RTOS to provide operating system (OS) time ticks. Future implementations of the Unified HW Timer will take advantage of low power timer peripherals that will allow OS ticks to continue when the system is in various lower power modes.

Hardware Abstraction Layer (HAL)

The KSDK HAL consists of low-level drivers for the Kinetis MCU product family on-chip peripherals. The main goal is to abstract the hardware peripheral register accesses into a set of stateless basic functional operations. The HAL itself can be used with system services to build application-specific logic or as building blocks for use-case driven high-level Peripheral Drivers. It primarily focuses on the functional control, configuration, and realization of basic peripheral operations. The HAL hides register access details and various MCU peripheral instantiation differences so that, either an application or high-level Peripheral Drivers, can be abstracted from the low-level HW details. Therefore, hardware peripheral must be accessed through HAL.

The HAL can also support some high-level functions with certain logic, provided these high-level functions do not depend on functions from other peripherals, nor impose any action to be taken in interrupt service routines. For example, the UART HAL provides a blocking byte-send function that relies only on the features available in the UART peripheral itself. These high-level functions enhance the usability of the HAL but remain stateless and independent of other peripherals. Essentially, the HAL functional boundary is limited by the peripheral itself. There is one HAL driver for each peripheral and the HAL only accesses the features available within the peripheral. In addition, the HAL does not define interrupt service routine entries or support interrupt handling. These tasks must be handled by a high-level Peripheral Driver together with the Interrupt Manager.

The HAL drivers can be found in the KSDK platform/hal directory.

Feature Header Files

The HAL is designed to be reusable regardless of the peripheral configuration differences from one Kinetis MCU device to another. An overall Peripheral Feature Header File is provided for KSDK-supported MCU device to define the feature or configuration differences for each Kinetis sub-family device.

Design Guidelines

This section summarizes the design guidelines that were used to develop the HAL drivers. It is meant for information purposes and provides more details on the make-up of the HAL drivers. As previously stated, the main goal of the HAL is to abstract the hardware details and provide a set of easy-to-use low-level drivers. The HAL itself can be used directly by the user application; in this case, the high-level Peripheral Drivers that are built on top of the HAL serve as a reference implementation and to demonstrate the HAL usage. The HAL is mainly focused on individual functional primitives and makes no assumption of use-cases. It also implements some high-level functions with certain logic without dependencies from other peripherals and does not impose any interrupt handling. The HAL APIs follow a naming convention that is consistent from one peripheral to the next. This is a summary of the design guidelines used when

developing the HAL drivers:

- There is a dedicated HAL driver for each individual peripheral. Peripherals with different versions or configurations are treated as the same peripheral with differences handled through a feature header file. HAL should hide both the peripheral and MCU details and differences from the high-level application and drivers.
- Each HAL driver has an initialization function to put the peripheral into a known default state (i.e., the peripheral reset state). There is no corresponding de-initialization function.
- Each HAL driver has an enable and disable function to enable or disable the peripheral module.
- The HAL driver does not have an internal operation context and should not dynamically allocate memory.
- The HAL provides both blocking and non-blocking functions for peripherals that support data transaction-related operations.
- The HAL may implement high-level functions based on abstracted functional primitives, provided this implementation does not depend on functions outside of the peripheral and does not involve interrupt handling. The HAL must remain stateless.
- The HAL driver does not depend on any other software entities or invoke any functions from other peripherals.

Peripheral Drivers

The KSDK Peripheral Drivers are use-case driven high-level drivers that implement high-level logic transactions based on one or more HAL drivers, other Peripheral Drivers, and/or System Services. Consider, for example, the differences in the UART HAL and the UART Peripheral Driver. The UART HAL mainly focuses on byte-level basic functional primitives, while the UART Peripheral Driver operates on an interrupt-driven level using data buffers to transfer a stream of bytes and may be able to interface with DMA Peripheral Driver for DMA-enabled transfers between data buffers. In general, if a driver, that is mainly based on one peripheral, interfaces with functions beyond its own HAL and/or requires interrupt servicing, the driver is considered a high-level Peripheral Driver.

The KSDK Peripheral Drivers support all instances of each peripheral instantiated on the Kinetis MCU by using a simple integer parameter for the peripheral instance number. Each Peripheral Driver includes a “common” file, denoted as `fsl_<peripheral>_common.c` (where `<peripheral>` is the name of the peripheral for which the driver is written). This file contains the translation of the peripheral instance number to the peripheral register base address, which is then passed into the HAL. Hence, the user of the Peripheral Driver does not need to know the peripheral memory-mapped base address.

The Peripheral Drivers operate on a high-level logic that requires data storage for internal operation context handling. However, the Peripheral Drivers do not allocate this memory space. Rather, the user passes in the memory for the driver internal operation through the driver initialization function. Note that HAL is used for MCUs with restricted RAM and FLASH size.

The Peripheral Drivers are designed to handle the entire functionality for a targeted use-case. An application should be able to use only the Peripheral Driver to accomplish its purpose. The mixing of the Peripheral Driver and HAL by an application for the same peripheral can be done, but is discouraged for architectural cleanliness and to avoid cases where bypassing the Peripheral Driver results in logic errors within the Peripheral Driver.

The Peripheral Drivers can be found in the KSDK `platform/drivers` directory.

Interrupt Handling

Interrupt-driven Peripheral Drivers are designed to service all interrupts for their desired functionality. Each Peripheral Driver implements a set of easy-to-use APIs for a particular use-case. Each Peripheral Driver also exposes interrupt functions that implement all actions taken when serving a particular interrupt. These interrupt action functions take in the peripheral instance number as an input parameter. All Interrupt Service Routine (ISR) entries for the Peripheral Driver are implemented in a separate C file named the `fsl_<peripheral>_irq.c`, which is located in the top level of the Peripheral Driver folder. The ISR entries invoke a corresponding interrupt action functions that are implemented in the driver and are exposed as part of the driver public interfaces. Each interrupt action function is hard coded with the peripheral instance number. Note that the IRQ file depends on the Peripheral Driver but the driver does not depend on the IRQ file.

The CMSIS startup code contains the vector table with the ISR entry names which are defined as weak references. The Peripheral Driver ISR entry names match the names defined in the vector table such that these newly-defined ISR entries in the driver replace the weak references defined in the vector table. There is no dependency on the location of the vector table. However, if the vector table is re-located (normally to RAM), the ISR entry names should remain consistent.

Each Peripheral Driver IRQ file defines the ISR entries for all instances of the peripheral instantiated on the MCU. Any unused ISR entries can be safely deleted in the user application. Note that, when building driver libraries for a particular MCU, the IRQ files are not part of the library build. When developing an application, however, include these IRQ files into the application project space.

If you want to use the HAL to directly build an interrupt-driven application or a high-level driver, define the ISR entries to service needed interrupts. The ISR entry names have to match the names of the ISR entry names provided in the CMSIS startup code vector table. Normally, the vector table is relocated to RAM during system startup and the ISR entry names remain unchanged. However, should these ISR entry names change, the user is required to register the newly defined ISR entry table names by invoking the Interrupt Manager registration function.

When working with an RTOS, if the target operating system has its own interrupt handling mechanism, the user's ISR has to dynamically register the internal vector table maintained inside the OS via the service routine provided by the OS. Some operating systems do not have dedicated interrupt handling, and no special handling is required. Most of the RTOSes designed for the Cortex-M core use PendSV exceptions for scheduling. The PendSV exceptions are low priority and execute only when all other interrupts have been serviced. There are special cases where interrupt handling prologues and epilogues have to be called at the beginning and at the end of an ISR to inform the OS of the entry and exit of an ISR so that the OS scheduler does not trigger a rescheduling event while the system is servicing interrupts. The OS Abstraction layer provides prologues and epilogues in a uniform API for all supported OS.

Peripheral Driver Types

Peripheral Drivers are designed and operated on use-case driven high-level logic. For that reason, the interaction between a Peripheral driver and other software components has a few limitations. This is a list of typical KSDK Peripheral Driver types to demonstrate this concept:

- Peripheral Drivers that use one HAL for a particular IP and system services
- Peripheral Drivers that use multiple HAL components and System Services. An example involves

a Peripheral Driver that uses both the DMA HAL and the I2C HAL to build a DMA-enabled high-level I2C driver. At the same time, a DMA Peripheral Driver already exists and provides the overall DMA channel management. In this situation, issues can arise for the dedicated DMA Peripheral Driver because it is unaware of use of resources for the DMA-enabled I2C driver that accesses the DMA HAL directly. In this case, the KSDK Peripheral Drivers will only use the DMA HAL when configuring the DMA Transfer Control Descriptor for a particular channel that is dedicated to the driver and avoid using the DMA HAL to change the DMA peripheral control registers. The DMA channel allocation for a particular Peripheral Driver is normally assigned during the initialization of the peripheral by calling the DMA Peripheral Driver channel request function. In this way, the DMA maintains a used channel registry.

- Peripheral Drivers that use a combination of HAL, other Peripheral Drivers, and System Services for solution-based composite high level drivers.

Design guidelines

This section summarizes the design guidelines to develop the Peripheral Drivers. In this list, the term Peripheral Driver is replaced with the acronym “PD”:

- The PD does not directly access hardware registers and only uses HAL to interface with hardware. It uses other PDs indirectly to access hardware functions.
- The PD does not dynamically allocate memory and does not assume any static configuration at compile-time. It supports run-time configurations by taking in a configuration data structure from the Application in an initialization function. This initialization function also takes in the memory allocated for internal operational context storage needs. The PD only reads from the configuration data structure. The configuration data structure is defined as “const”.
- The PD supports an initialization function and has a corresponding de-initialization function.
- The PD supports both blocking and non-blocking functions for data transactions.
- The PD does not depend on any software or hardware entities that do not relate to any of the peripherals available on the Kinetis platform. For example, the Ethernet (ENET) PD does not depend on an external ENET PHY, even if the ENET PD does not function without an associated external PHY.
- If the PD is built on top of HAL, the PD can work with any instance of the peripheral by taking the instance number as a parameter. When global data is shared across multiple instances, the global data access has to be protected when working with an RTOS. This can be done using the critical section functions implemented as part of the RTOS abstraction. This data access protection is addressed with the bare-metal OS abstraction implementation when no RTOS is used.
- When the ISR and other public API functions within the driver access the PD internal operation context, that data must be defined as volatile so that compiler does not inadvertently optimize the code resulting in an undesired functionality.
- The PD provides enough functions to allow the APIs provided by PD to meet the target use-case implementation. The user application should not mix the use of both a PD and HAL .
- The PD does not configure pin muxing or set up interrupt priorities for related interrupts. Those items are handled by the board-specific configuration and the application-specific logic.

Demo Applications

The Demo Applications provided in the KSDK provide examples, which show how to build user applications using the KSDK framework. The Demo Applications can be found in the KSDK top-level demo

directory. The KSDK includes two types of demo applications:

- Demo Applications that demonstrate the usage of the Peripheral Drivers.
- Demo Applications that provide a reference design based on the features available on the target Kinetis MCU and evaluation boards. This type of demo is targeted to highlight a certain feature of the SOC for its intended usage, and/or to provide turnkey references using the KSDK driver library with other integrated software components such as USB stacks.

Board Configuration

The KSDK drivers make no assumption on board-specific configurations nor do the drivers configure pin muxing, which are part of the board-specific configuration. The KSDK provides board-configuration files that un-gate clocks for related I/O ports, configure pin muxing for the entire board, and functions that can be called before driver initialization. These board-configuration files can be found in the KSDK top-level board directory.

In addition, the KSDK also contains a set of drivers in the boards/common directory for common devices (such as SPI flash and ENET PHY) found on the Kinetis platform evaluation boards. These drivers are included mainly for a convenient out-of-box experience and to demonstrate how to build use-case-driven reference designs.

OS Abstraction layer

The KSDK drivers are designed to work with or without an RTOS. The Operating System Abstraction layer (OSA) is designed and implemented for supported RTOS to provide a common set of service routines for drivers, integrated software solution, and upper-level applications so that a common code base can be used regardless of the target OS.

The services supported by the OSA are driven by the driver requirements, supported middleware, and applications. The OSA layer is designed to be as thin as possible. The OSA either maps the desired services to the services provided by the target OS or implements the services that the target OS does not support.

The OSA itself does not dynamically allocate memory for implementing an OS service component. Instead, the memory for OS components is allocated by the caller and is passed into the OSA for servicing. The OSA drivers can be found in the KSDK platform/osa directory.

Software Stacks and other Middleware integration

The core of the Kinetis SDK is a set of common driver libraries built for all Kinetis MCU product family peripherals. Kinetis SDK also provides a foundation for software stacks and other middleware. The KSDK integrates other Freescale or third party enablement software stacks, such as a USB stack and a TCP/IP stack and other middleware, to offer a complete, easy-to-use, software development kit to the Kinetis MCU users. The KSDK framework integrates all Kinetis MCU software solutions for the Kinetis product families.

Chapter 3

16-bit SAR Analog-to-Digital Converter (ADC16)

3.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the 16-bit SAR Analog-to-Digital Converter (ADC16) block of Kinetis devices.

Modules

- [ADC16 HAL Driver](#)
- [ADC16 Peripheral Driver](#)

ADC16 HAL Driver

3.2 ADC16 HAL Driver

3.2.1 Overview

This section describes the programming interface of the ADC16 HAL driver.

Data Structures

- struct `adc16_chn_config_t`
Defines the structure to configure the ADC16 channel. [More...](#)
- struct `adc16_converter_config_t`
Defines the structure to configure the ADC16's converter. [More...](#)
- struct `adc16_hw_cmp_config_t`
Defines the structure to configure the ADC16 internal comparator. [More...](#)

Enumerations

- enum `adc16_status_t` {
`kStatus_ADC16_Success` = 0U,
`kStatus_ADC16_InvalidArgument` = 1U,
`kStatus_ADC16_Failed` = 2U }
ADC16 status return codes.
- enum `adc16_clk_divider_t` {
`kAdc16ClkDividerOf1` = 0U,
`kAdc16ClkDividerOf2` = 1U,
`kAdc16ClkDividerOf4` = 2U,
`kAdc16ClkDividerOf8` = 3U }
Defines the type of the enumerating divider for the converter.
- enum `adc16_resolution_t` {
`kAdc16ResolutionBitOf8or9` = 0U,
`kAdc16ResolutionBitOfSingleEndAs8` = `kAdc16ResolutionBitOf8or9`,
`kAdc16ResolutionBitOfDiffModeAs9` = `kAdc16ResolutionBitOf8or9`,
`kAdc16ResolutionBitOf12or13` = 1U,
`kAdc16ResolutionBitOfSingleEndAs12` = `kAdc16ResolutionBitOf12or13`,
`kAdc16ResolutionBitOfDiffModeAs13` = `kAdc16ResolutionBitOf12or13`,
`kAdc16ResolutionBitOf10or11` = 2U,
`kAdc16ResolutionBitOfSingleEndAs10` = `kAdc16ResolutionBitOf10or11`,
`kAdc16ResolutionBitOfDiffModeAs11` = `kAdc16ResolutionBitOf10or11` }
Defines the type of the enumerating resolution for the converter.
- enum `adc16_clk_src_mode_t` {
`kAdc16ClkSrcOfBusClk` = 0U,
`kAdc16ClkSrcOfAltClk2` = 1U,
`kAdc16ClkSrcOfAltClk` = 2U,
`kAdc16ClkSrcOfAsynClk` = 3U }
Defines the type of the enumerating source of the input clock.

- enum `adc16_long_sample_cycle_t` {
 `kAdc16LongSampleCycleOf24` = 0U,
 `kAdc16LongSampleCycleOf16` = 1U,
 `kAdc16LongSampleCycleOf10` = 2U,
 `kAdc16LongSampleCycleOf6` = 3U }
 Defines the type of the enumerating long sample cycles.
- enum `adc16_ref_volt_src_t` {
 `kAdc16RefVoltSrcOfVref` = 0U,
 `kAdc16RefVoltSrcOfValt` = 1U }
 Defines the type of the enumerating reference voltage source.
- enum `adc16_chn_t` {

ADC16 HAL Driver

```

kAdc16Chn0 = 0U,
kAdc16Chn1 = 1U,
kAdc16Chn2 = 2U,
kAdc16Chn3 = 3U,
kAdc16Chn4 = 4U,
kAdc16Chn5 = 5U,
kAdc16Chn6 = 6U,
kAdc16Chn7 = 7U,
kAdc16Chn8 = 8U,
kAdc16Chn9 = 9U,
kAdc16Chn10 = 10U,
kAdc16Chn11 = 11U,
kAdc16Chn12 = 12U,
kAdc16Chn13 = 13U,
kAdc16Chn14 = 14U,
kAdc16Chn15 = 15U,
kAdc16Chn16 = 16U,
kAdc16Chn17 = 17U,
kAdc16Chn18 = 18U,
kAdc16Chn19 = 19U,
kAdc16Chn20 = 20U,
kAdc16Chn21 = 21U,
kAdc16Chn22 = 22U,
kAdc16Chn23 = 23U,
kAdc16Chn24 = 24U,
kAdc16Chn25 = 25U,
kAdc16Chn26 = 26U,
kAdc16Chn27 = 27U,
kAdc16Chn28 = 28U,
kAdc16Chn29 = 29U,
kAdc16Chn30 = 30U,
kAdc16Chn31 = 31U,
kAdc16Chn0d = kAdc16Chn0,
kAdc16Chn1d = kAdc16Chn1,
kAdc16Chn2d = kAdc16Chn2,
kAdc16Chn3d = kAdc16Chn3,
kAdc16Chn4a = kAdc16Chn4,
kAdc16Chn5a = kAdc16Chn5,
kAdc16Chn6a = kAdc16Chn6,
kAdc16Chn7a = kAdc16Chn7,
kAdc16Chn4b = kAdc16Chn4,
kAdc16Chn5b = kAdc16Chn5,
kAdc16Chn6b = kAdc16Chn6,
kAdc16Chn7b = kAdc16Chn7 }

```

Defines the type of enumerating ADC16's channel index.

Variables

- `adc16_chn_t adc16_chn_config_t::chnIdx`
Select the sample channel index.
- `bool adc16_chn_config_t::convCompletedIntEnable`
Enable the conversion complete interrupt.
- `bool adc16_converter_config_t::lowPowerEnable`
Enables low power.
- `adc16_clk_divider_t adc16_converter_config_t::clkDividerMode`
Selects the divider of input clock source.
- `bool adc16_converter_config_t::longSampleTimeEnable`
Enables the long sample time.
- `adc16_resolution_t adc16_converter_config_t::resolution`
Selects the sample resolution mode.
- `adc16_clk_src_mode_t adc16_converter_config_t::clkSrc`
Selects the input clock source to converter.
- `bool adc16_converter_config_t::asyncClkEnable`
Enables the asynchronous clock inside the ADC.
- `bool adc16_converter_config_t::highSpeedEnable`
Enables the high-speed mode.
- `adc16_long_sample_cycle_t adc16_converter_config_t::longSampleCycleMode`
Selects the long sample mode.
- `bool adc16_converter_config_t::hwTriggerEnable`
Enables the hardware trigger function.
- `adc16_ref_volt_src_t adc16_converter_config_t::refVoltSrc`
Selects the reference voltage source.
- `bool adc16_converter_config_t::continuousConvEnable`
Enables continuous conversion mode.
- `bool adc16_hw_cmp_config_t::hwCmpEnable`
Enables the hardware compare function.
- `bool adc16_hw_cmp_config_t::hwCmpGreaterThanEnable`
Configures the compare function.
- `bool adc16_hw_cmp_config_t::hwCmpRangeEnable`
Configures the comparator function.
- `uint16_t adc16_hw_cmp_config_t::cmpValue1`
Setting value for CV1.
- `uint16_t adc16_hw_cmp_config_t::cmpValue2`
Setting value for CV2.

ADC16 HAL.

- `void ADC16_HAL_Init (ADC_Type *base)`
Resets all registers into a known state for the ADC16 module.
- `void ADC16_HAL_ConfigChn (ADC_Type *base, uint32_t chnGroup, const adc16_chn_config_t *configPtr)`
Configures the conversion channel for the ADC16 module.
- `static bool ADC16_HAL_GetChnConvCompletedFlag (ADC_Type *base, uint32_t chnGroup)`
Checks whether the channel conversion is completed.
- `void ADC16_HAL_ConfigConverter (ADC_Type *base, const adc16_converter_config_t *configPtr)`

ADC16 HAL Driver

- Configures the sampling converter for the ADC16.*

 - void `ADC16_HAL_ConfigHwCompare` (ADC_Type *base, const `adc16_hw_cmp_config_t` *configPtr)
- Configures the hardware comparator function for the ADC16.*

 - static uint16_t `ADC16_HAL_GetChnConvValue` (ADC_Type *base, uint32_t chnGroup)

Gets the raw result data of channel conversion for the ADC16 module.
- static bool `ADC16_HAL_GetConvActiveFlag` (ADC_Type *base)

Checks whether the converter is active for the ADC16 module.

3.2.2 Data Structure Documentation

3.2.2.1 struct `adc16_chn_config_t`

This type of variable is treated as the command to be set in ADC control register, which may execute the ADC's conversion.

Data Fields

- `adc16_chn_t chnIdx`
Select the sample channel index.
- bool `convCompletedIntEnable`
Enable the conversion complete interrupt.

3.2.2.2 struct `adc16_converter_config_t`

This type of variable is treated as a group of configurations. Most of the time, these configurations are a one-time setting for converter sampling condition. Usually, they are set before executing the ADC16 job.

Data Fields

- bool `lowPowerEnable`
Enables low power.
- `adc16_clk_divider_t clkDividerMode`
Selects the divider of input clock source.
- bool `longSampleTimeEnable`
Enables the long sample time.
- `adc16_resolution_t resolution`
Selects the sample resolution mode.
- `adc16_clk_src_mode_t clkSrc`
Selects the input clock source to converter.
- bool `asyncClkEnable`
Enables the asynchronous clock inside the ADC.
- bool `highSpeedEnable`
Enables the high-speed mode.
- `adc16_long_sample_cycle_t longSampleCycleMode`
Selects the long sample mode.

- bool `hwTriggerEnable`
Enables the hardware trigger function.
- `adc16_ref_volt_src_t refVoltSrc`
Selects the reference voltage source.
- bool `continuousConvEnable`
Enables continuous conversion mode.

3.2.2.3 struct `adc16_hw_cmp_config_t`

Data Fields

- bool `hwCmpEnable`
Enables the hardware compare function.
- bool `hwCmpGreaterThanEnable`
Configures the compare function.
- bool `hwCmpRangeEnable`
Configures the comparator function.
- `uint16_t cmpValue1`
Setting value for CV1.
- `uint16_t cmpValue2`
Setting value for CV2.

3.2.3 Enumeration Type Documentation

3.2.3.1 enum `adc16_status_t`

Enumerator

- `kStatus_ADC16_Success` Success.
- `kStatus_ADC16_InvalidArgument` Invalid argument.
- `kStatus_ADC16_Failed` Execution failed.

3.2.3.2 enum `adc16_clk_divider_t`

Enumerator

- `kAdc16ClkDividerOf1` For divider 1 from the input clock to ADC16.
- `kAdc16ClkDividerOf2` For divider 2 from the input clock to ADC16.
- `kAdc16ClkDividerOf4` For divider 4 from the input clock to ADC16.
- `kAdc16ClkDividerOf8` For divider 8 from the input clock to ADC16.

3.2.3.3 enum `adc16_resolution_t`

Enumerator

- `kAdc16ResolutionBitOf8or9` 8-bit for single end sample, or 9-bit for differential sample.

ADC16 HAL Driver

- kAdc16ResolutionBitOfSingleEndAs8* 8-bit for single end sample.
- kAdc16ResolutionBitOfDiffModeAs9* 9-bit for differential sample.
- kAdc16ResolutionBitOfI2orI3* 12-bit for single end sample, or 13-bit for differential sample.
- kAdc16ResolutionBitOfSingleEndAsI2* 12-bit for single end sample.
- kAdc16ResolutionBitOfDiffModeAsI3* 13-bit for differential sample.
- kAdc16ResolutionBitOfI10orI11* 10-bit for single end sample, or 11-bit for differential sample.
- kAdc16ResolutionBitOfSingleEndAsI0* 10-bit for single end sample.
- kAdc16ResolutionBitOfDiffModeAsI1* 11-bit for differential sample.

3.2.3.4 enum adc16_clk_src_mode_t

Enumerator

- kAdc16ClkSrcOfBusClk* For input as bus clock.
- kAdc16ClkSrcOfAltClk2* For input as alternate clock 2 (AltClk2).
- kAdc16ClkSrcOfAltClk* For input as alternate clock (ALTCLK).
- kAdc16ClkSrcOfAsynClk* For input as asynchronous clock (ADACK).

3.2.3.5 enum adc16_long_sample_cycle_t

Enumerator

- kAdc16LongSampleCycleOf24* 20 extra ADCK cycles, 24 ADCK cycles total.
- kAdc16LongSampleCycleOf16* 12 extra ADCK cycles, 16 ADCK cycles total.
- kAdc16LongSampleCycleOf10* 6 extra ADCK cycles, 10 ADCK cycles total.
- kAdc16LongSampleCycleOf6* 2 extra ADCK cycles, 6 ADCK cycles total.

3.2.3.6 enum adc16_ref_volt_src_t

Enumerator

- kAdc16RefVoltSrcOfVref* For external pins pair of VrefH and VrefL.
- kAdc16RefVoltSrcOfValt* For alternate reference pair of ValtH and ValtL.

3.2.3.7 enum adc16_chn_t

Enumerator

- kAdc16Chn0* AD0.
- kAdc16Chn1* AD1.
- kAdc16Chn2* AD2.
- kAdc16Chn3* AD3.

kAdc16Chn4 AD4.
kAdc16Chn5 AD5.

kAdc16Chn6b AD6b.
kAdc16Chn7b AD7b.

ADC16 HAL Driver

3.2.4 Function Documentation

3.2.4.1 void ADC16_HAL_Init (ADC_Type * *base*)

This function resets all registers into a known state for the ADC module. This known state is the reset value indicated by the Reference manual. It is strongly recommended to call this API before any other operation when initializing the ADC16 module.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

3.2.4.2 void ADC16_HAL_ConfigChn (ADC_Type * *base*, uint32_t *chnGroup*, const adc16_chn_config_t * *configPtr*)

This function configures the channel for the ADC16 module. At any point, only one of the configuration groups takes effect. The other channel group of the first group (group A, 0) is only for the hardware trigger. Both software and hardware trigger can be used to the first group. When in software trigger mode, after the available channel is set, the conversion begins to execute.

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>chnGroup</i> | Channel configuration group ID. |
| <i>configPtr</i> | Pointer to configuration structure. |

3.2.4.3 static bool ADC16_HAL_GetChnConvCompletedFlag (ADC_Type * *base*, uint32_t *chnGroup*) [inline], [static]

This function checks whether the channel conversion for the ADC module is completed.

Parameters

| | |
|-----------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>chnGroup</i> | Channel configuration group ID. |

Returns

Assertion of completed conversion mode.

3.2.4.4 void ADC16_HAL_ConfigConverter (ADC_Type * *base*, const adc16_converter_config_t * *configPtr*)

This function configures the sampling converter for the ADC16. Most of the time, the configurations are a one-time setting for the converter sampling condition. Usually, it is called before executing the ADC16 job.

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

3.2.4.5 void ADC16_HAL_ConfigHwCompare (ADC_Type * *base*, const adc16_hw_cmp_config_t * *configPtr*)

This function configures the hardware comparator function for the ADC16. These are the settings for the ADC16 comparator.

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

3.2.4.6 static uint16_t ADC16_HAL_GetChnConvValue (ADC_Type * *base*, uint32_t *chnGroup*) [inline], [static]

This function gets the conversion result data for the ADC16 module. The return value is the raw data that is not processed.

Parameters

| | |
|-----------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>chnGroup</i> | Channel configuration group ID. |

Returns

Conversion value of RAW.

3.2.4.7 static bool ADC16_HAL_GetConvActiveFlag (ADC_Type * *base*) [inline], [static]

This function checks whether the converter is active for the ADC16 module.

ADC16 HAL Driver

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

Assertion of that the converter is active.

3.2.5 Variable Documentation

3.2.5.1 `adc16_chn_t adc16_chn_config_t::chnIdx`

3.2.5.2 `bool adc16_chn_config_t::convCompletedIntEnable`

3.3 ADC16 Peripheral Driver

3.3.1 Overview

This section describes the programming interface of the ADC16 Peripheral driver. The ADC16 peripheral driver configures the ADC16 (16-bit SAR Analog-to-Digital Converter). It handles calibration, initialization, and configuration of 16-bit SAR ADC module.

3.3.2 ADC16 Driver model building

ADC16 driver has three parts:

- **Basic Converter** - This part handles the mechanism that converts the external analog voltage to a digital value. API functions configure the converter.
- **Channel Mux** - Multiple channels share the converter in each ADC instance because of the time division multiplexing. However, the converter can only handle one channel at a time. To get the value of an indicated channel, the channel mux should be set to the connection between an indicated pad and the converter's input. The conversion value during this period is for the channel only. API functions configure the channel.
- **Advance Feature Group** - The advanced feature group covers optional features for applications. These features includes some that are already implemented by hardware, such as the calibration, hardware average, hardware compare, different power, and speed mode. APIs configure the advanced features. Although these features are optional, they are recommended to ensure that the ADC performs better, especially for calibration.

3.3.3 ADC16 Initialization

Note that the calibration should be done before any other operation.

To initialize the ADC16 driver, prepare a configuration structure and populate it with an available configuration. API functions are designed for typical use cases and facilitate populating the structure. See the "Call diagram" section for typical use cases. Additionally, the application should provide a block of memory to keep the state while the driver operates. After the configuration structure is available and memory is allocated to keep state, the ADC module can be initialized by calling the API of [ADC16_DRV_Init\(\)](#) function.

3.3.4 ADC16 Call diagram

There are three kinds of typical use cases for the ADC module:

- **One-Time-Trigger Mode**. One-Time-Trigger works without an interrupt and continuous mode. After it is triggered by channel configuration, the conversion launches and the application gets the result data. There is no auto operation to make the conversion continuous. The application should trigger the conversion again if another conversion is needed.

ADC16 Peripheral Driver

- **Interrupt mode** - Interrupt mode works only with continuous conversion or one-time conversion. To use the interrupt mode, the user enables the interrupt when configuring for each conversion. Note that the conversion value should be read out by calling the API of the "ADC16_DRV_GetConvValueRAW()" in the user-defined ISR. Use the interrupt mode carefully with the continuous conversion because too many interrupts may affect the main routine. Using the low conversion speed is recommended in the continuous interrupt mode.
- **Blocking mode.** Blocking mode is based on polling mode and works only with the continuous conversion mode. The conversion is triggered by the channel configuration. When the conversion is completed, it gets blocked because the result data is not read. The application obtains the result data by calling API. After this, the conversion becomes continuous.

These use cases are based on the software trigger. However, they can easily be ported to use the hardware trigger. If using the hardware trigger, enable it when initializing the converter.

Complex use cases, such as the DMA and the multiple channel scan, require another module to work correctly. They can be customized according to the application.

These are the examples to initialize and configure the ADC driver for typical use cases.

For One-Time-Trigger use:

```
uint32_t ADC16_DRV_TEST_OneTimeConv(uint32_t instance)
{
    uint32_t errCounter = 0U;
    adc16_converter_config_t userConvConfig;
    adc16_chn_config_t userChnConfig;
    uint16_t sampleValue;
#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    adc16_calibration_param_t userCalConfig;
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION

    /* Execute the auto-calibration.
    userConvConfig.lowPowerEnable = false;
    userConvConfig.clkDividerMode = kAdc16ClkDividerOf8;
    userConvConfig.longSampleTimeEnable = true;
    userConvConfig.resolution = kAdc16ResolutionBitOf12or13;
    userConvConfig.clkSrc = kAdc16ClkSrcOfAsynClk;
    userConvConfig.asyncClkEnable = true;
    userConvConfig.highSpeedEnable = false;
    userConvConfig.longSampleCycleMode = kAdc16LongSampleCycleOf24;
    userConvConfig.hwTriggerEnable = false;
    userConvConfig.refVoltSrc = kAdc16RefVoltSrcOfVref;
    userConvConfig.continuousConvEnable = false;
#ifdef FSL_FEATURE_ADC16_HAS_DMA
    userConvConfig.dmaEnable = false;
#endif /* FSL_FEATURE_ADC16_HAS_DMA

    if (kStatus_ADC16_Success != ADC16_DRV_Init(instance, &userConvConfig))
    {
        errCounter++;
    }

#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    if (kStatus_ADC16_Success != ADC16_DRV_GetAutoCalibrationParam(instance, &userCalConfig) )
    {
        errCounter++;
    }
    ADC16_DRV_SetCalibrationParam(instance, &userCalConfig);
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION
```

```

userChnConfig.chnIdx = ADC16_DRV_TEST_SAMPLE_CHN;
userChnConfig.convCompletedIntEnable = false;
userChnConfig.diffConvEnable = false;
ADC16_DRV_ConfigConvChn(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP, &userChnConfig);

ADC16_DRV_WaitConvDone(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP);
sampleValue = ADC16_DRV_GetConvValueRAW(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP);
printf("ADC16_DRV_TEST_OneTimeConv Sample Value: %d\r\n", sampleValue);

ADC16_DRV_Deinit(instance);

return errCounter;
}

```

For Interrupt use:

```

static uint32_t ADC16_DRV_TEST_OneTimeConvInt(uint32_t instance)
{
    uint32_t errCounter = 0U;
    adc16_converter_config_t userConvConfig;
    adc16_chn_config_t userChnConfig;
    uint16_t sampleValue;

#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    adc16_calibration_param_t userCalConfig;
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION

    /* Execute the auto-calibration.
    userConvConfig.lowPowerEnable = false;
    userConvConfig.clkDividerMode = kAdc16ClkDividerOf8;
    userConvConfig.longSampleTimeEnable = true;
    userConvConfig.resolution = kAdc16ResolutionBitOf12or13;
    userConvConfig.clkSrc = kAdc16ClkSrcOfAsynClk;
    userConvConfig.asyncClkEnable = true;
    userConvConfig.highSpeedEnable = false;
    userConvConfig.longSampleCycleMode = kAdc16LongSampleCycleOf24;
    userConvConfig.hwTriggerEnable = false;
    userConvConfig.refVoltSrc = kAdc16RefVoltSrcOfVref;
    userConvConfig.continuousConvEnable = false;
#ifdef FSL_FEATURE_ADC16_HAS_DMA
    userConvConfig.dmaEnable = false;
#endif /* FSL_FEATURE_ADC16_HAS_DMA

    if (kStatus_ADC16_Success != ADC16_DRV_Init(instance, &userConvConfig))
    {
        errCounter++;
    }

#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    if (kStatus_ADC16_Success != ADC16_DRV_GetAutoCalibrationParam(instance, &userCalConfig) )
    {
        errCounter++;
    }
    ADC16_DRV_SetCalibrationParam(instance, &userCalConfig);
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION

    gAdc16IntSampleFlag = false;

    userChnConfig.chnIdx = ADC16_DRV_TEST_SAMPLE_CHN;
    userChnConfig.convCompletedIntEnable = true;
    userChnConfig.diffConvEnable = false;
    ADC16_DRV_ConfigConvChn(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP, &userChnConfig);

    while (!gAdc16IntSampleFlag) {}
    printf("ADC16_DRV_TEST_OneTimeConvInt Sample Value: %d\r\n", gAdc16IntSampleValue);

```

ADC16 Peripheral Driver

```

    gAdc16IntSampleFlag = false;

    ADC16_DRV_Deinit(instance);

    return errCounter;
}

```

For Blocking use:

```

static uint32_t ADC16_DRV_TEST_ContinuousConvBlocking(uint32_t instance)
{
    uint32_t errCounter = 0U;
    adc16_converter_config_t userConvConfig;
    adc16_chn_config_t userChnConfig;
    uint16_t sampleValue;
    uint32_t i;

#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    adc16_calibration_param_t userCalConfig;
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION

    /* Execute the auto-calibration.
    userConvConfig.lowPowerEnable = false;
    userConvConfig.clkDividerMode = kAdc16ClkDividerOf8;

    userConvConfig.clkSrc = kAdc16ClkSrcOfAsynClk;
    userConvConfig.asyncClkEnable = true;
    userConvConfig.highSpeedEnable = false;
    userConvConfig.longSampleCycleMode = kAdc16LongSampleCycleOf24;
    userConvConfig.hwTriggerEnable = false;
    userConvConfig.refVoltSrc = kAdc16RefVoltSrcOfVref;
    userConvConfig.continuousConvEnable = false;
#ifdef FSL_FEATURE_ADC16_HAS_DMA
    userConvConfig.dmaEnable = false;
#endif /* FSL_FEATURE_ADC16_HAS_DMA

    if (kStatus_ADC16_Success != ADC16_DRV_Init(instance, &userConvConfig))
    {
        errCounter++;
    }

#ifdef FSL_FEATURE_ADC16_HAS_CALIBRATION
    if (kStatus_ADC16_Success != ADC16_DRV_GetAutoCalibrationParam(instance, &userCalConfig) )
    {
        errCounter++;
    }
    ADC16_DRV_SetCalibrationParam(instance, &userCalConfig);
#endif /* FSL_FEATURE_ADC16_HAS_CALIBRATION

    userChnConfig.chnIdx = ADC16_DRV_TEST_SAMPLE_CHN;
    userChnConfig.convCompletedIntEnable = false;
    userChnConfig.diffConvEnable = false;
    ADC16_DRV_ConfigConvChn(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP, &userChnConfig);

    for (i = 0U; i < 4U; i++)
    {
        sampleValue = ADC16_DRV_GetConvValueRAW(instance, ADC16_DRV_TEST_SAMPLE_CHNGROUP);
        printf("ADC16_DRV_TEST_ContinuousConvBlocking %dst Sample Value: %d\r\n", i, sampleValue);
    }

    ADC16_DRV_Deinit(instance);
    return errCounter;
}

```

Enumerations

- enum `adc16_flag_t` {
`kAdcConvActiveFlag = 0U`,
`kAdcChnConvCompleteFlag = 3U` }
Defines the type of event flags.

Functions

- `adc16_status_t ADC16_DRV_StructInitUserConfigDefault` (`adc16_converter_config_t *userConfigPtr`)
Fills the initial user configuration by default for a one-time trigger mode.
- `adc16_status_t ADC16_DRV_Init` (`uint32_t instance`, `const adc16_converter_config_t *userConfigPtr`)
Initializes the ADC module converter.
- `adc16_status_t ADC16_DRV_Deinit` (`uint32_t instance`)
De-initializes the ADC module converter.
- `adc16_status_t ADC16_DRV_ConfigHwCompare` (`uint32_t instance`, `const adc16_hw_cmp_config_t *configPtr`)
Configures the hardware compare feature.
- `adc16_status_t ADC16_DRV_ConfigConvChn` (`uint32_t instance`, `uint32_t chnGroup`, `const adc16_chn_config_t *configPtr`)
Configure the conversion channel by software.
- `void ADC16_DRV_WaitConvDone` (`uint32_t instance`, `uint32_t chnGroup`)
Waits for the latest conversion to be complete.
- `void ADC16_DRV_PauseConv` (`uint32_t instance`, `uint32_t chnGroup`)
Pauses the current conversion by software.
- `uint16_t ADC16_DRV_GetConvValueRAW` (`uint32_t instance`, `uint32_t chnGroup`)
Gets the latest conversion value with no format.
- `int16_t ADC16_DRV_GetConvValueSigned` (`uint32_t instance`, `uint32_t chnGroup`)
Gets the latest conversion value with signed.
- `bool ADC16_DRV_GetConvFlag` (`uint32_t instance`, `adc16_flag_t flag`)
Gets the event status of the ADC16 module.
- `bool ADC16_DRV_GetChnFlag` (`uint32_t instance`, `uint32_t chnGroup`, `adc16_flag_t flag`)
Gets the event status of each channel group.

Variables

- `ADC_Type *const g_adcBase` []
Table of base addresses for ADC16 instances.
- `const IRQn_Type g_adcIrqId` [ADC_INSTANCE_COUNT]
Table to save ADC IRQ enum numbers defined in the CMSIS header file.

ADC16 Peripheral Driver

3.3.5 Enumeration Type Documentation

3.3.5.1 enum adc16_flag_t

Enumerator

kAdcConvActiveFlag Indicates if a conversion or hardware averaging is in progress.

kAdcChnConvCompleteFlag Indicates if the channel group A is ready.

3.3.6 Function Documentation

3.3.6.1 adc16_status_t ADC16_DRV_StructInitUserConfigDefault (adc16_converter_config_t * userConfigPtr)

This function fills the initial user configuration by default for a one-time trigger mode. Calling the initialization function with the filled parameter configures the ADC module work as one-time trigger mode. The settings are:

- .lowPowerEnable = true;
- .clkDividerMode = kAdc16ClkDividerOf8;
- .longSampleTimeEnable = true;
- .resolutionMode = kAdc16ResolutionBitOfSingleEndAs12;
- .clkSrc = kAdc16ClkSrcOfAsynClk
- .asynClkEnable = true;
- .highSpeedEnable = false;
- .longSampleCycleMode = kAdc16LongSampleCycleOf24;
- .hwTriggerEnable = false;
- .refVoltSrc = kAdcRefVoltSrcOfVref;
- .continuousConvEnable = false;
- .dmaEnable = false;

Parameters

| | |
|----------------------|--|
| <i>userConfigPtr</i> | Pointer to the user configuration structure. See the "adc16_converter_config_t". |
|----------------------|--|

Returns

Execution status.

3.3.6.2 adc16_status_t ADC16_DRV_Init (uint32_t instance, const adc16_converter_config_t * userConfigPtr)

This function initializes the converter in the ADC module.

Parameters

| | |
|----------------------|--|
| <i>instance</i> | ADC16 instance ID. |
| <i>userConfigPtr</i> | Pointer to the initialization structure. See the "adc16_converter_config_t". |

Returns

Execution status.

3.3.6.3 `adc16_status_t ADC16_DRV_Deinit (uint32_t instance)`

This function de-initializes and gates the ADC module. When ADC is no longer used, calling this API function shuts down the device to reduce the power consumption.

Parameters

| | |
|-----------------|--------------------|
| <i>instance</i> | ADC16 instance ID. |
|-----------------|--------------------|

Returns

Execution status.

3.3.6.4 `adc16_status_t ADC16_DRV_ConfigHwCompare (uint32_t instance, const adc16_hw_cmp_config_t * configPtr)`

This function configures the hardware compare feature with indicated configuration.

Parameters

| | |
|------------------|--|
| <i>instance</i> | ADC16 instance ID. |
| <i>configPtr</i> | Pointer to configuration structure. See the "adc16_hw_cmp_config_t". |

Returns

Execution status.

3.3.6.5 `adc16_status_t ADC16_DRV_ConfigConvChn (uint32_t instance, uint32_t chnGroup, const adc16_chn_config_t * configPtr)`

This function configures the conversion channel. When the ADC16 module has been initialized by enabling the software trigger (disable hardware trigger), calling this API triggers the conversion.

ADC16 Peripheral Driver

Parameters

| | |
|------------------|---|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | Selection of the configuration group. |
| <i>configPtr</i> | Pointer to configuration structure. See the "adc16_chn_config_t". |

Returns

Execution status.

3.3.6.6 void ADC16_DRV_WaitConvDone (uint32_t *instance*, uint32_t *chnGroup*)

This function waits for the latest conversion to be complete. When triggering the conversion by configuring the available channel, the converter is launched. This API function should be called to wait for the conversion to be complete when no interrupt or DMA mode is used for the ADC16 module. After the waiting period, the available data from the conversion result are fetched. The complete flag is not cleared until the result data is read.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | Selection of configuration group. |

3.3.6.7 void ADC16_DRV_PauseConv (uint32_t *instance*, uint32_t *chnGroup*)

This function pauses the current conversion setting by software.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | Selection of configuration group. |

3.3.6.8 uint16_t ADC16_DRV_GetConvValueRAW (uint32_t *instance*, uint32_t *chnGroup*)

This function gets the conversion value from the ADC16 module.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | Selection of configuration group. |

Returns

Unformatted conversion value.

3.3.6.9 int16_t ADC16_DRV_GetConvValueSigned (uint32_t instance, uint32_t chnGroup)

This function gets the conversion value from the ADC16 module with signed.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | Selection of configuration group. |

Returns

Signed conversion value.

3.3.6.10 bool ADC16_DRV_GetConvFlag (uint32_t instance, adc16_flag_t flag)

This function gets the event status of the ADC16 converter. If the event is asserted, it returns "true". Otherwise, it is "false".

Parameters

| | |
|-----------------|--------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>flag</i> | Indicated event. |

Returns

Assertion of event flag.

3.3.6.11 bool ADC16_DRV_GetChnFlag (uint32_t instance, uint32_t chnGroup, adc16_flag_t flag)

This function gets the event status of each channel group. If the event is asserted, it returns "true". Otherwise, it is "false".

ADC16 Peripheral Driver

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | ADC16 instance ID. |
| <i>chnGroup</i> | ADC16 channel group number. |
| <i>flag</i> | Indicated event. |

Returns

Assertion of event flag.

3.3.7 Variable Documentation

3.3.7.1 `ADC_Type* const g_adcBase[]`

3.3.7.2 `const IRQn_Type g_adclrqld[ADC_INSTANCE_COUNT]`

Chapter 4

Analog Front End (AFE)

4.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Analog Front End (AFE) block of Kinetis devices.

Modules

- [AFE HAL driver](#)
- [AFE Peripheral driver](#)

AFE HAL driver

4.2 AFE HAL driver

4.2.1 Overview

This section describes the programming interface of the AFE HAL driver.

Data Structures

- struct [afe_chn_set_t](#)
Defines the structure to configure the AFE Channel. [More...](#)
- struct [afe_converter_config_t](#)
Defines the structure to configure the AFE converter. [More...](#)

Enumerations

- enum [afe_status_t](#) {
[kStatus_AFE_Success](#) = 0U,
[kStatus_AFE_InvalidArgument](#) = 1U,
[kStatus_AFE_Failed](#) = 2U }
AFE status return codes.
- enum [afe_chn_osr_mode_t](#) {
[kAfeDecimOsrOf64](#) = 0U,
[kAfeDecimOsrOf128](#) = 1U,
[kAfeDecimOsrOf256](#) = 2U,
[kAfeDecimOsrOf512](#) = 3U,
[kAfeDecimOsrOf1024](#) = 4U,
[kAfeDecimOsrOf2048](#) = 5U }
AFE OSR modes.
- enum [afe_pga_gain_mode_t](#) {
[kAfePgaGainBy1](#) = 1U,
[kAfePgaGainBy2](#) = 2U,
[kAfePgaGainBy4](#) = 3U,
[kAfePgaGainBy8](#) = 4U,
[kAfePgaGainBy16](#) = 5U,
[kAfePgaGainBy32](#) = 6U }
AFE PGA modes.
- enum [afe_result_format_mode_t](#) {
[kAfeResultFormatLeft](#) = 0U,
[kAfeResultFormatRight](#) = 1U }
Defines the AFE result format modes.
- enum [afe_clk_divider_mode_t](#) {

```

kAfeClkDividerInputOf1 = 0U,
kAfeClkDividerInputOf2 = 1U,
kAfeClkDividerInputOf4 = 2U,
kAfeClkDividerInputOf8 = 3U,
kAfeClkDividerInputOf16 = 4U,
kAfeClkDividerInputOf32 = 5U,
kAfeClkDividerInputOf64 = 6U,
kAfeClkDividerInputOf128 = 7U,
kAfeClkDividerInputOf256 = 8U }

```

Defines the AFE clock divider modes.

- enum `afe_clk_src_mode_t` {

```

kAfeClkSrcClk0 = 0U,
kAfeClkSrcClk1 = 1U,
kAfeClkSrcClk2 = 2U,
kAfeClkSrcClk3 = 3U }

```

Defines the AFE clock source modes.

AFE Channel Configurations

- void `AFE_HAL_ChnInit` (AFE_Type *base, uint32_t chn)
 - Resets the channel registers into a reset state.*
- static void `AFE_HAL_SetIntEnableCmd` (AFE_Type *base, uint32_t chn, bool enable)
 - Sets the interrupt request on conversion complete event.*
- static void `AFE_HAL_SetDmaEnableCmd` (AFE_Type *base, uint32_t chn, bool enable)
 - Sets the DMA request on conversion complete event.*
- static void `AFE_HAL_SetDelayVal` (AFE_Type *base, uint32_t chn, int32_t delay)
 - Sets the delay value.*
- static int32_t `AFE_HAL_GetDelayVal` (AFE_Type *base, uint32_t chn)
 - Gets the delay value.*
- static uint32_t `AFE_HAL_GetResult` (AFE_Type *base, uint32_t chn)
 - Gets the measurement result.*
- static bool `AFE_HAL_GetConvCompleteFlag` (AFE_Type *base, uint32_t chn)
 - Checks whether a conversion is completed.*
- static bool `AFE_HAL_GetOverflowFlag` (AFE_Type *base, uint32_t chn)
 - Checks whether the selected channel has overflowed.*
- static bool `AFE_HAL_GetReadyFlag` (AFE_Type *base, uint32_t chn)
 - Checks whether the selected channel is ready for conversion.*

AFE Common Configurations

- void `AFE_HAL_Init` (AFE_Type *base)
 - Resets all registers into a reset state for the AFE module.*
- static void `AFE_HAL_SetMasterEnableCmd` (AFE_Type *base, bool enable)
 - Enables all ADCs and filters.*
- static void `AFE_HAL_ChnSwTriggerCmd` (AFE_Type *base, uint32_t chnMask)
 - Triggers conversion on the AFE channels.*
- static void `AFE_HAL_SetLowPowerCmd` (AFE_Type *base, bool enable)

AFE HAL driver

- Sets a low power mode.*

 - static void [AFE_HAL_SetSwResetCmd](#) (AFE_Type *base, bool enable)
- Sets the software reset.*

 - static void [AFE_HAL_SetDelayOkCmd](#) (AFE_Type *base)
- Asserts the delay OK.*

 - static void [AFE_HAL_SetResultFormatMode](#) (AFE_Type *base, [afe_result_format_mode_t](#) mode)
- Selects the result format mode.*

 - static [afe_result_format_mode_t](#) [AFE_HAL_GetResultFormatMode](#) (AFE_Type *base)
- Gets the conversion resolution mode.*

 - static void [AFE_HAL_SetStartUpDelayVal](#) (AFE_Type *base, int32_t startDelay)
- Sets the start up count value.*

 - static void [AFE_HAL_SetClkDividerMode](#) (AFE_Type *base, [afe_clk_divider_mode_t](#) mode)
- Selects the clock divider mode.*

 - static void [AFE_HAL_SetClkSourceMode](#) (AFE_Type *base, [afe_clk_src_mode_t](#) mode)
- Selects the input clock source for the AFE module.*

 - static void [AFE_HAL_SetDmaIntReq](#) (AFE_Type *base, uint32_t data)
- Sets the DMA and interrupt requests for all channels.*

 - void [AFE_HAL_ConfigChn](#) (AFE_Type *base, uint32_t chn, [afe_chn_set_t](#) *chnStructPtr)
- Configures the AFE channel.*

 - void [AFE_HAL_ConfigConverter](#) (AFE_Type *base, [afe_converter_config_t](#) *converterStructPtr)
- Configures the AFE converter.*

4.2.2 Data Structure Documentation

4.2.2.1 struct afe_chn_set_t

Data Fields

- bool [hwTriggerEnable](#)
Enable triggering by hardware.
- bool [continuousConvEnable](#)
Enable continuous conversion mode.
- bool [bypassEnable](#)
Enable bypass mode that modulator and PGA of this channel are disabled.
- [afe_pga_gain_mode_t](#) [pgaGainSel](#)
Select the analog gain applied to the input signal.
- bool [pgaEnable](#)
Enable the analog gain.
- [afe_chn_osr_mode_t](#) [decimOSR](#)
Select the over sampling ration.
- bool [modulatorEnable](#)
Enable sigma delta modulator.
- bool [decimFilterEnable](#)
Enable decimation filter.
- bool [decimNedgeEnable](#)
Enable falling edge for decimator input.
- bool [externClockEnable](#)
Enable external clock for decimator.

4.2.2.1.0.1 Field Documentation

4.2.2.1.0.1.1 `bool afe_chn_set_t::hwTriggerEnable`

4.2.2.1.0.1.2 `bool afe_chn_set_t::continuousConvEnable`

4.2.2.1.0.1.3 `bool afe_chn_set_t::bypassEnable`

4.2.2.1.0.1.4 `afe_pga_gain_mode_t afe_chn_set_t::pgaGainSel`

4.2.2.1.0.1.5 `bool afe_chn_set_t::pgaEnable`

4.2.2.1.0.1.6 `afe_chn_osr_mode_t afe_chn_set_t::decimOSR`

4.2.2.1.0.1.7 `bool afe_chn_set_t::modulatorEnable`

4.2.2.2 `struct afe_converter_config_t`

Data Fields

- `uint8_t startupCnt`
Set startup delay of modulators.
- `afe_result_format_mode_t resultFormat`
Select the result format.
- `bool delayOk`
Confirm delay registers.
- `bool swReset`
Do a software reset.
- `bool lowPowerEnable`
Enable low power mode.
- `bool swTriggChn0`
Trigger conversion on channel 0.
- `bool swTriggChn1`
Trigger conversion on channel 1.
- `bool swTriggChn2`
Trigger conversion on channel 2.
- `bool masterEnable`
Enable all ADCs and filters simultaneously whose modulatorEnable and decimFilterEnable is asserted.

AFE HAL driver

4.2.2.2.0.2 Field Documentation

4.2.2.2.0.2.1 `uint8_t afe_converter_config_t::startupCnt`

4.2.2.2.0.2.2 `afe_result_format_mode_t afe_converter_config_t::resultFormat`

4.2.2.2.0.2.3 `bool afe_converter_config_t::delayOk`

4.2.2.2.0.2.4 `bool afe_converter_config_t::swReset`

4.2.2.2.0.2.5 `bool afe_converter_config_t::lowPowerEnable`

4.2.2.2.0.2.6 `bool afe_converter_config_t::swTriggChn0`

4.2.2.2.0.2.7 `bool afe_converter_config_t::swTriggChn1`

4.2.2.2.0.2.8 `bool afe_converter_config_t::swTriggChn2`

4.2.2.2.0.2.9 `bool afe_converter_config_t::masterEnable`

4.2.3 Enumeration Type Documentation

4.2.3.1 `enum afe_status_t`

Enumerator

kStatus_AFE_Success Success.

kStatus_AFE_InvalidArgument Invalid argument existed.

kStatus_AFE_Failed Execution failed.

4.2.3.2 `enum afe_chn_osr_mode_t`

Enumerator

kAfeDecimOsrOf64 Decimator over sampling ratio is 64.

kAfeDecimOsrOf128 Decimator over sampling ratio is 128.

kAfeDecimOsrOf256 Decimator over sampling ratio is 256.

kAfeDecimOsrOf512 Decimator over sampling ratio is 512.

kAfeDecimOsrOf1024 Decimator over sampling ratio is 1024.

kAfeDecimOsrOf2048 Decimator over sampling ratio is 2048.

4.2.3.3 `enum afe_pga_gain_mode_t`

Enumerator

kAfePgaGainBy1 Input gained by 1.

kAfePgaGainBy2 Input gained by 2.

- kAfePgaGainBy4* Input gained by 4.
- kAfePgaGainBy8* Input gained by 8.
- kAfePgaGainBy16* Input gained by 16.
- kAfePgaGainBy32* Input gained by 32.

4.2.3.4 enum afe_result_format_mode_t

Enumerator

- kAfeResultFormatLeft* Left justified result format.
- kAfeResultFormatRight* Right justified result format.

4.2.3.5 enum afe_clk_divider_mode_t

Enumerator

- kAfeClkDividerInputOf1* Clock divided by 1.
- kAfeClkDividerInputOf2* Clock divided by 2.
- kAfeClkDividerInputOf4* Clock divided by 4.
- kAfeClkDividerInputOf8* Clock divided by 8.
- kAfeClkDividerInputOf16* Clock divided by 16.
- kAfeClkDividerInputOf32* Clock divided by 32.
- kAfeClkDividerInputOf64* Clock divided by 64.
- kAfeClkDividerInputOf128* Clock divided by 128.
- kAfeClkDividerInputOf256* Clock divided by 256.

4.2.3.6 enum afe_clk_src_mode_t

Enumerator

- kAfeClkSrcClk0* Modulator clock source 0.
- kAfeClkSrcClk1* Modulator clock source 1.
- kAfeClkSrcClk2* Modulator clock source 2.
- kAfeClkSrcClk3* Modulator clock source 3.

4.2.4 Function Documentation

4.2.4.1 void AFE_HAL_ChnInit (AFE_Type * base, uint32_t chn)

This function resets the channel registers into a reset state. This state is defined in the chip Reference Manual.

AFE HAL driver

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>chn</i> | AFE Channel. |

4.2.4.2 `static void AFE_HAL_SetIntEnableCmd (AFE_Type * base, uint32_t chn, bool enable) [inline], [static]`

This function sets the interrupt request on conversion complete event. Once enabled, the conversion complete interrupt request is asserted for the desired channel when INTENx and COCx bits are set.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |
| <i>enable</i> | Bool value for enabling or disabling interrupt function. |

4.2.4.3 `static void AFE_HAL_SetDmaEnableCmd (AFE_Type * base, uint32_t chn, bool enable) [inline], [static]`

This function sets the DMA request on conversion complete event. Once enabled, the DMA request is asserted when the INTENx and the COCx bits are set.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |
| <i>enable</i> | Bool value for enabling or disabling DMA function. |

4.2.4.4 `static void AFE_HAL_SetDelayVal (AFE_Type * base, uint32_t chn, int32_t delay) [inline], [static]`

This function sets the delay value. This delay is inserted into the trigger response of the decimation filters in order to provide phase compensation between AFE channels.

Parameters

| | |
|--------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |
| <i>delay</i> | Delay value. |

**4.2.4.5 static int32_t AFE_HAL_GetDelayVal (AFE_Type * *base*, uint32_t *chn*)
[inline], [static]**

This function gets the delay value.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |

Returns

Delay value.

**4.2.4.6 static uint32_t AFE_HAL_GetResult (AFE_Type * *base*, uint32_t *chn*)
[inline], [static]**

This function gets the measurement result. The result can be represented in left justified twos complement 32-bit or right justified twos complement 32-bit format. See the "AFE_HAL_SetResultFormatMode()" for format setting.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |

Returns

result.

**4.2.4.7 static bool AFE_HAL_GetConvCompleteFlag (AFE_Type * *base*, uint32_t *chn*)
[inline], [static]**

This function checks whether the conversion is completed. When the result is read (see the "AFE_HAL_GetResult()"), the corresponding bit is cleared.

AFE HAL driver

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |

Returns

Conversion is completed (true) or not (false).

4.2.4.8 static bool AFE_HAL_GetOverflowFlag (AFE_Type * *base*, uint32_t *chn*) [inline], [static]

This function checks whether the selected channel has overflow. This function returns true when new data has already arrived but previous data has not been read. The corresponding bit is cleared when the result is read (see the "AFE_HAL_GetResult()").

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |

Returns

Channel is overflowed (true) or not (false).

4.2.4.9 static bool AFE_HAL_GetReadyFlag (AFE_Type * *base*, uint32_t *chn*) [inline], [static]

This function checks whether the selected channel is ready for conversion.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |

Returns

Channel is ready to initiate conversions (true) or is disabled or has not completed its start up period (false).

4.2.4.10 void AFE_HAL_Init (AFE_Type * *base*)

This function resets all registers into a reset state for the AFE module. This state is defined in the chip Reference Manual.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

**4.2.4.11 static void AFE_HAL_SetMasterEnableCmd (AFE_Type * *base*, bool *enable*)
[inline], [static]**

This function enables all ADCs and filters. The only ADCs that have asserted are SD_MOD_EN (only when AFE channel is not bypassed) and DEC_EN () are enabled by setting this bit.

Parameters

| | |
|---------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>enable</i> | Bool value for enabling or disabling ADCs and filters simultaneously. |

**4.2.4.12 static void AFE_HAL_ChnSwTriggerCmd (AFE_Type * *base*, uint32_t *chnMask*)
[inline], [static]**

This function sets the software trigger conversion on the desired AFE channels. To trigger more channels simultaneously, use the red enumeration members.

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chnMask</i> | Channels which will be triggered. |

**4.2.4.13 static void AFE_HAL_SetLowPowerCmd (AFE_Type * *base*, bool *enable*)
[inline], [static]**

This function sets an AFE low power mode. The maximal modulator clock in low power mode is below 1 MHz.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the AFE module. |
| <i>enable</i> | Bool value for enabling or disabling low power mode. |

AFE HAL driver

4.2.4.14 `static void AFE_HAL_SetSwResetCmd (AFE_Type * base, bool enable) [inline], [static]`

This function sets the software reset which is used to reset all ADCs, decimation filters, and clock configuration bits.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the AFE module. |
| <i>enable</i> | If this value is true, all ADCs, PGAs and decimation filters are enabled. Otherwise, are disabled. |

4.2.4.15 `static void AFE_HAL_SetDelayOkCmd (AFE_Type * base) [inline], [static]`

This function asserts the delay OK. When all delay registers are loaded, the delay OK bit should be asserted.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
|-------------|---|

4.2.4.16 `static void AFE_HAL_SetResultFormatMode (AFE_Type * base, afe_result_format_mode_t mode) [inline], [static]`

This function selects the result format mode.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>mode</i> | Selection of mode enumeration. See to "afe_result_format_mode_t". |

4.2.4.17 `static afe_result_format_mode_t AFE_HAL_GetResultFormatMode (AFE_Type * base) [inline], [static]`

This function gets the conversion resolution mode.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
|-------------|---|

Returns

Current conversion resolution mode.

4.2.4.18 static void AFE_HAL_SetStartUpDelayVal (AFE_Type * *base*, int32_t *startDelay*) [inline], [static]

This function sets the start up count value. A minimum value is two. This value should be greater than 20 μ s. To compute the 20 μ s value use, such as $startDelay = (CLOCK_FREQ / DIV_factor) * 20E-6$

Parameters

| | |
|-------------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>startDelay</i> | Value for start up count. |

4.2.4.19 static void AFE_HAL_SetClkDividerMode (AFE_Type * *base*, afe_clk_divider_mode_t *mode*) [inline], [static]

This function selects the clock divider mode.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>mode</i> | Selection of mode enumeration. See to "afe_clk_divider_mode_t". |

4.2.4.20 static void AFE_HAL_SetClkSourceMode (AFE_Type * *base*, afe_clk_src_mode_t *mode*) [inline], [static]

This function selects the input clock source for the AFE module.

Parameters

AFE HAL driver

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>mode</i> | Selection of mode enumeration. See to "afe_clk_src_mode_t". |

4.2.4.21 static void AFE_HAL_SetDmaIntReq (AFE_Type * *base*, uint32_t *data*) [inline], [static]

This function sets a DMA and Interrupt requests for all channels.

Parameters

| | |
|-------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>data</i> | which will be written to register. |

4.2.4.22 void AFE_HAL_ConfigChn (AFE_Type * *base*, uint32_t *chn*, afe_chn_set_t * *chnStructPtr*)

This function configures the AFE channel.

Parameters

| | |
|---------------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>chn</i> | AFE Channel. |
| <i>chnStructPtr</i> | Channel configuration structure. |

4.2.4.23 void AFE_HAL_ConfigConverter (AFE_Type * *base*, afe_converter_config_t * *converterStructPtr*)

This function configures an AFE converter.

Parameters

| | |
|----------------------------|---|
| <i>base</i> | Register base address for the AFE module. |
| <i>converter-StructPtr</i> | Converter configuration structure. |

AFE Peripheral driver

4.3 AFE Peripheral driver

4.3.1 Overview

This section describes the programming interface of the AFE Peripheral driver. The AFE peripheral driver provides functions to initialize AFE module and channels, conversion triggering, and result reading.

4.3.2 Channel configuration structures

The driver uses instances of the channel configuration structures to configuration and initialization AFE channel. This structure holds the settings of the AFE measurement channel. The settings include AFE hardware/software triggering, AFE continuous/Single conversion mode, AFE phase delay compensation, AFE channel mode, AFE channel analog gain, AFE channel oversampling ration, and AFE channel interrupt or DMA function. The AFE channel mode selects whether the bypass mode is enabled or disabled and the external clock selection.

4.3.3 User configuration structures

The AFE driver uses instances of the user configuration structure `afe_user_config_t` for the AFE driver configuration. This structure holds the configuration which is common for all AFE channels. The settings include AFE low power mode, AFE result format, AFE clock divider mode, AFE clock source mode, and AFE start up delay of modulators.

4.3.4 Initialization

1. To initialize the AFE driver, call the `AFE_DRV_Init()` function and pass the instance number of the AFE peripheral and a pointer to the user configuration structure. For a typical use case, call the `AFE_DRV_StructInitUserConfigDefault()` function which populates the structure.
2. Then, call the `AFE_DRV_ChnInit` function and pass the instance number, channel number and a pointer to the channel configuration structure. For a typical use case, call the `AFE_DRV_StructInitChnConfigDefault()` function which populates the structure.
3. The start up value can be set by the `AFE_DRV_SetStartUpVal20us()` function call or by filling the `startupCnt` parameter of the `AfeChnConfig` structure.
4. If the phase delay values are configured, call the `AFE_DRV_AssertDelayOk()` function and pass the instance number.
5. Finally, call the `AFE_DRV_Enable()` function and pass the instance number and a true boolean parameter. Ensure that the clock and VREF are configured properly before configuring the AFE. For more information, see a VREF and documentation for the KSDK Clock Manager.

```
typedef struct AfeUserConfig
{
    bool lowPowerEnable;
```

This is an example of a typical AFE configuration. The `afe_user_config_t` instantiation is configured in the normal mode (low power mode disabled), result format is justified to the right, clock divider is selected 2 and a first clock source is selected (see the microcontroller documentation for information about these selections). The `afe_chn_config_t` instantiation is configured in the normal mode (no bypass), a continuous conversion, a zero delay, no interrupt or DMA request, the software trigger enabled, and the PGA disabled and the OSR is 2048.

This is an example code to set up a user and a channel AFE configuration instantiation:

```
afe_user_config_t afeConfig;
afeConfig.clkDividerMode = kAfeClkDividerInputOf2;
afeConfig.clkSrcMode = kAfeClkSrcClk1;
afeConfig.lowPowerEnable = false;
afeConfig.resultFormat = kAfeResultFormatRight;
afeTestStruct.startupCnt = 80; // startupCnt = (Clk_freq/Clk_div)*20e-6

afe_chn_config_t afeChnConfig;
afeChnConfig.chnMode = kAfeNormal;
afeChnConfig.continuousConvEnable = true;
afeChnConfig.delay = 0;
afeChnConfig.chnEvent = kAfeNoneReq;
afeChnConfig.hwTriggerEnable = false;
afeChnConfig.pgaGainSel = kAfePgaDisable;
afeChnConfig.decimOSR = kAfeDecimOsrOf2048;
```

This example shows how to call the `AFE_DRV_Init()` given the user configuration structure and the AFE instance 0.

```
uint32_t afeInstance = 0;
UART_DRV_Init(afeInstance, &afeConfig);
```

This example shows how to call the `AFE_DRV_ChnInit()` given the channel configuration structure and the AFE channel 0 and 1.

```
uint32_t afeChannel0 = 0;
uint32_t afeChannel1 = 1;
AFE_DRV_ChnInit(afeInstance, afeChannel0, &afeChnConfig); // Configure AFE channel 0
AFE_DRV_ChnInit(afeInstance, afeChannel1, &afeChnConfig); // Configure AFE channel 1
```

The last part of the initialization contains the start up count setting, delay values confirmation, and the AFE module enabling.

```
AFE_DRV_AssertDelayOk(afeInstance); // Assert delay for all channels simultaneously
AFE_DRV_Enable(afeInstance, true); // Enable all configured channels
```

4.3.5 Measuring

The driver contains functions for software triggering, a channel delay after trigger setting, a result (raw or converted to right justified), reading and waiting functions.

If the software triggering is enabled (`hwTriggerEnable` parameter in `afe_chn_config` is a false value), call the `AFE_DRV_SoftTriggerConv()` function to start conversion. In this example, the channel 0 and channel 1 are triggered simultaneously. After the conversion is completed, the results are read.

AFE Peripheral driver

```
int32_t res0, res1;

AFE_DRV_SoftTriggerConv(afeInstance, CHN_TRIG_MASK(0) | CHN_TRIG_MASK(1));

while(1)
{
    AFE_DRV_WaitConvDone(afeInstance, 0);
    AFE_DRV_WaitConvDone(afeInstance, 1);

    res0 = AFE_DRV_GetChnConvValue(afeInstance, 0);
    res1 = AFE_DRV_GetChnConvValue(afeInstance, 1);
}
```

If the hardware triggering is enabled (hwTriggerEnable parameter in afe_chn_config is a true value), the [AFE_DRV_SoftTriggerConv\(\)](#) function isn't called. The rest of the code is the same.

If the continuous conversion isn't allowed (continuousConvEnable parameter in afe_chn_config is a false value), call the [AFE_DRV_SoftTriggerConv\(\)](#) function (in the software trigger case) in the main loop to trigger the next conversion.

Data Structures

- struct [afe_chn_config_t](#)
Defines the structure to initialize the AFE channel. [More...](#)
- struct [afe_user_config_t](#)
Defines the structure to initialize the AFE module. [More...](#)
- struct [afe_delay_config_t](#)
Defines the structure to configure phase delay of each AFE channel. [More...](#)

Enumerations

- enum [afe_pga_state_t](#) {
[kAfePgaDisable](#) = 0U,
[kAfePgaGain1](#) = 1U,
[kAfePgaGain2](#) = 2U,
[kAfePgaGain4](#) = 3U,
[kAfePgaGain8](#) = 4U,
[kAfePgaGain16](#) = 5U,
[kAfePgaGain32](#) = 6U }
Defines the PGA's values.
- enum [afe_chn_mode_t](#) {
[kAfeNormal](#) = 0,
[kAfeBypassExternClkPosEdge](#) = 1,
[kAfeBypassExternClkNegEdge](#) = 2,
[kAfeBypassInternClkPosEdge](#) = 3,
[kAfeBypassInternClkNegEdge](#) = 4 }
Defines the channel's modes.

- enum `afe_chn_event_t` {
`kAfeNoneReq` = 0,
`kAfeIntReq` = 1,
`kAfeDmaReq` = 2 }
Defines the channel's event requests.
- enum `afe_flag_t` {
`kAfeOverflowFlag` = 0U,
`kAfeReadyFlag` = 1U,
`kAfeConvCompleteFlag` = 2U }
Defines the type of event flags.

Functions

- `afe_status_t AFE_DRV_StructInitUserConfigDefault` (`afe_user_config_t *userConfigPtr`)
Fills the user configure structure.
- `afe_status_t AFE_DRV_StructInitChnConfigDefault` (`afe_chn_config_t *chnConfigPtr`)
Fills the channel configuration structure.
- `afe_status_t AFE_DRV_Init` (`uint32_t instance`, `afe_user_config_t *userConfigPtr`)
Initializes the AFE module.
- `afe_status_t AFE_DRV_ChnInit` (`uint32_t instance`, `uint32_t chn`, `afe_chn_config_t *chnConfigPtr`)
Initializes the selected AFE channel.
- void `AFE_DRV_Enable` (`uint32_t instance`, `bool enable`)
Enables/disables all configured AFE channels.
- void `AFE_DRV_WaitConvDone` (`uint32_t instance`, `uint32_t chn`)
Waits until the last conversion is complete.
- void `AFE_DRV_WaitChnReady` (`uint32_t instance`, `uint32_t chn`)
Waits until the channel is ready for conversion.
- void `AFE_DRV_SoftTriggerConv` (`uint32_t instance`, `uint32_t chnMask`)
Triggers the AFE conversion by software.
- bool `AFE_DRV_GetChnFlag` (`uint32_t instance`, `uint32_t chn`, `afe_flag_t flag`)
Gets the flag for channel's events.
- `uint32_t AFE_DRV_GetChnConvValRaw` (`uint32_t instance`, `uint32_t chn`)
Reads the conversion value in a raw form.
- `int32_t AFE_DRV_GetChnConvVal` (`uint32_t instance`, `uint32_t chn`)
Reads the conversion value in 2's complement form.
- void `AFE_DRV_Deinit` (`uint32_t instance`)
De-initializes the AFE module.
- void `AFE_DRV_ChnDeinit` (`uint32_t instance`, `uint32_t chn`)
De-initializes the selected AFE channel.
- void `AFE_DRV_AssertDelayOk` (`uint32_t instance`)
Asserts the phase delay setting.
- void `AFE_DRV_SetPhaseDelays` (`uint32_t instance`, `afe_delay_config_t *delayConfigPtr`)
Sets phase delays.

Variables

- `AFE_Type *const g_afeBase` []
Table of base addresses for AFE instances.

AFE Peripheral driver

- const IRQn_Type [g_afeIrqId](#) []
Table to save AFE IRQ enumeration numbers defined in CMSIS header file.

4.3.6 Data Structure Documentation

4.3.6.1 struct afe_chn_config_t

This structure keeps the configuration for the AFE channel.

Data Fields

- bool [hwTriggerEnable](#)
Enable triggering by hardware.
- bool [continuousConvEnable](#)
Enable continuous conversion mode.
- uint32_t [delay](#)
Set the phase compensation.
- [afe_chn_mode_t](#) [chnMode](#)
Select if channel is in bypassed mode.
- [afe_pga_state_t](#) [pgaGainSel](#)
Select the analog gain applied to the input signal.
- [afe_chn_osr_mode_t](#) [decimOSR](#)
Select the over sampling ration.
- [afe_chn_event_t](#) [chnEvent](#)
Select DMA or interrupt function.

4.3.6.2 struct afe_user_config_t

This structure keeps the configuration for the AFE module.

Data Fields

- bool [lowPowerEnable](#)
Enable low power mode.
- [afe_result_format_mode_t](#) [resultFormat](#)
Select the result format.
- [afe_clk_divider_mode_t](#) [clkDividerMode](#)
Select the clock divider ration for the modulator clock.
- [afe_clk_src_mode_t](#) [clkSrcMode](#)
Select clock source for modulator clock.
- uint8_t [startupCnt](#)
Select the start up delay of modulators.

4.3.6.3 struct afe_delay_config_t

This structure keeps the phase delay of each AFE channel.

Data Fields

- uint32_t `delayChn0`
Phase compensation of channel0.
- uint32_t `delayChn1`
Phase compensation of channel1.
- uint32_t `delayChn2`
Phase compensation of channel2.

4.3.6.3.0.3 Field Documentation

4.3.6.3.0.3.1 uint32_t afe_delay_config_t::delayChn0

4.3.6.3.0.3.2 uint32_t afe_delay_config_t::delayChn1

4.3.6.3.0.3.3 uint32_t afe_delay_config_t::delayChn2

4.3.7 Enumeration Type Documentation

4.3.7.1 enum afe_pga_state_t

Enumerator

- kAfePgaDisable* PGA disabled.
- kAfePgaGain1* Input gained by 1.
- kAfePgaGain2* Input gained by 2.
- kAfePgaGain4* Input gained by 4.
- kAfePgaGain8* Input gained by 8.
- kAfePgaGain16* Input gained by 16.
- kAfePgaGain32* Input gained by 32.

4.3.7.2 enum afe_chn_mode_t

Enumerator

- kAfeNormal* Normal channel mode.
- kAfeBypassExternClkPosEdge* Bypassed channel mode - external clock selected, positive edge for registering data by the decimation filter.
- kAfeBypassExternClkNegEdge* Bypassed channel mode - external clock selected, negative edge for registering data by the decimation filter.
- kAfeBypassInternClkPosEdge* Bypassed channel mode - internal clock selected, positive edge for registering data by the decimation filter.

AFE Peripheral driver

kAfeBypassInternClkNegEdge Bypassed channel mode - external clock selected, negative edge for registering data by the decimation filter.

4.3.7.3 enum afe_chn_event_t

Enumerator

kAfeNoneReq None request is enabled if conversion is completed.

kAfeIntReq Interrupt request is enabled if conversion is completed.

kAfeDmaReq DMA request is enabled if conversion is completed.

4.3.7.4 enum afe_flag_t

Enumerator

kAfeOverflowFlag Indicates if a previous conversion result has not been read and new data has already arrived.

kAfeReadyFlag Indicates whether a channel is ready to conversion.

kAfeConvCompleteFlag Indicates whether a conversion is complete.

4.3.8 Function Documentation

4.3.8.1 afe_status_t AFE_DRV_StructInitUserConfigDefault (afe_user_config_t * userConfigPtr)

This function fills the [afe_user_config_t](#) structure with default settings. These setting are:

```
.lowPowerEnable = false
.resultFormat = kAfeResultFormatLeft
.clkDividerMode = kAfeClkDividerInputOf2
.clkSrcMode = kAfeClkSrcClk0
.startupCnt = 125
```

Parameters

| | |
|----------------------|--|
| <i>userConfigPtr</i> | Pointer to structure of "afe_user_config_t". |
|----------------------|--|

Returns

Execution status.

4.3.8.2 afe_status_t AFE_DRV_StructInitChnConfigDefault (afe_chn_config_t * chnConfigPtr)

This function fills the [afe_chn_config_t](#) structure with default settings. These setting are:

```
.hwTriggerEnable = false
.continuousConvEnable = false
.chnMode = kAfeNormal
.decimOSR = kAfeDecOsrOf64
.delay = 0
.pgaGainSel = kAfePgaGain1
.chnEvent = kAfeNoneReq
```

Parameters

| | |
|---------------------|---|
| <i>chnConfigPtr</i> | Pointer to structure of "afe_chn_config_t". |
|---------------------|---|

Returns

Execution status.

4.3.8.3 afe_status_t AFE_DRV_Init (uint32_t instance, afe_user_config_t * userConfigPtr)

This function configures the AFE module for the configuration which are shared by all channels.

Parameters

| | |
|----------------------|--|
| <i>instance</i> | The AFE instance number. |
| <i>userConfigPtr</i> | Pointer to structure of "afe_user_config_t". If startupCnt parameter is less than two, this value is calculated according to equation $Statup_cnt = (clk_freq/clk_div)*20e-6$. |

Returns

Execution status.

4.3.8.4 afe_status_t AFE_DRV_ChnInit (uint32_t instance, uint32_t chn, afe_chn_config_t * chnConfigPtr)

This function configures the selected AFE channel.

AFE Peripheral driver

Parameters

| | |
|---------------------|---|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | Channel which will be triggered. |
| <i>chnConfigPtr</i> | Pointer to structure of "afe_chn_config_t". |

Returns

Execution status.

4.3.8.5 void AFE_DRV_Enable (uint32_t *instance*, bool *enable*)

This function enables or disables all channels whose SD_MOD_EN and DEC_EN bits are asserted.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The AFE instance number. |
| <i>enable</i> | Enable (true) or disable (false) all ADCs and filters. |

4.3.8.6 void AFE_DRV_WaitConvDone (uint32_t *instance*, uint32_t *chn*)

This function holds the program until the last conversion is complete.

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | Channel which is triggered. |

4.3.8.7 void AFE_DRV_WaitChnReady (uint32_t *instance*, uint32_t *chn*)

This function holds the program until the channel is ready for conversion.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
|-----------------|--------------------------|

| | |
|------------|-----------------------------|
| <i>chn</i> | Channel which is triggered. |
|------------|-----------------------------|

4.3.8.8 void AFE_DRV_SoftTriggerConv (uint32_t *instance*, uint32_t *chnMask*)

This function triggers the AFE conversion by executing a software command. It starts the conversion on selected channels if the software trigger option is selected for the channels.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chnMask</i> | Channel(s) mask which is triggered. |

4.3.8.9 bool AFE_DRV_GetChnFlag (uint32_t *instance*, uint32_t *chn*, afe_flag_t *flag*)

This function returns the selected flag of the desired channel.

Parameters

| | |
|-----------------|---------------------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | The AFE Channel. |
| <i>flag</i> | Indicated event, see to "afe_flag_t". |

Returns

Assertion of indicated event.

4.3.8.10 uint32_t AFE_DRV_GetChnConvValRaw (uint32_t *instance*, uint32_t *chn*)

This function returns the conversion value of the selected channel. The returned value could be left or right adjusted according to the AFE module configuration.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | The AFE Channel. |

AFE Peripheral driver

Returns

Conversion value.

4.3.8.11 `int32_t AFE_DRV_GetChnConvVal (uint32_t instance, uint32_t chn)`

This function returns the conversion value of the selected channel. The returned value is in the two's complement (right adjusted) format.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | The AFE Channel. |

Returns

Conversion value in 2's complement format.

4.3.8.12 `void AFE_DRV_Deinit (uint32_t instance)`

When the AFE is no longer used, calling this function shuts down the device to reduce power consumption.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
|-----------------|--------------------------|

4.3.8.13 `void AFE_DRV_ChnDeinit (uint32_t instance, uint32_t chn)`

De-initializes the selected AFE channel configuration and interrupt.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
| <i>chn</i> | The AFE Channel. |

4.3.8.14 void AFE_DRV_AssertDelayOk (uint32_t *instance*)

This function should be called after all desired channel's delay registers are loaded. Values in channel's delay registers are active after calling this function and after the conversation starts.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | The AFE instance number. |
|-----------------|--------------------------|

4.3.8.15 void AFE_DRV_SetPhaseDelays (uint32_t *instance*, afe_delay_config_t * *delayConfigPtr*)

This function sets the phase delays for channels. This delay is inserted before the trigger response of the decimation filters. The delay is used to provide a phase compensation between AFE channels in step of prescaled modulator clock periods. The DelayOk bit is asserted in this function and the '[AFE_DRV_AssertDelayOk\(\)](#)' function doesn't have to be called. The delays for each channel are stored in a '[afe_delay_config_t](#)' structure.

Parameters

| | |
|-----------------------|---|
| <i>instance</i> | The AFE instance number. |
| <i>delayConfigPtr</i> | Pointer to structure of " afe_delay_config_t ". |

4.3.9 Variable Documentation

4.3.9.2 const IRQn_Type g_afeIrqId[]

Chapter 5

Crossbar AND/OR/INVERT (AOI) Module

5.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Crossbar AND/OR/INVERT module of Kinetis devices.

Modules

- [AOI HAL Driver](#)
- [AOI Peripheral Driver](#)

AOI HAL Driver

5.2 AOI HAL Driver

5.2.1 Overview

The section describes the programming interface of the AOI HAL driver. AOI HAL driver is a set of API functions used to access and configure the AOI hardware registers.

Enumerations

- enum `aoi_status_t` {
`kStatus_AOI_Success` = 0U,
`kStatus_AOI_InvalidArgument` = 1U,
`kStatus_AOI_Failed` = 2U }
AOI status return codes.
- enum `aoi_input_config_t` {
`kAoiConfigLogicZero` = 0x0U,
`kAoiConfigInputSignal` = 0x1U,
`kAoiConfigInvInputSignal` = 0x2U,
`kAoiConfigLogicOne` = 0x3U }
Defines the product term numbers.
- enum `aoi_product_term_t` {
`kAoiTerm0` = 0x0U,
`kAoiTerm1` = 0x1U,
`kAoiTerm2` = 0x2U,
`kAoiTerm3` = 0x3U }
Defines the product term numbers.
- enum `aoi_input_signal_index_t` {
`kAoiInputA` = 0x0U,
`kAoiInputB` = 0x1U,
`kAoiInputC` = 0x2U,
`kAoiInputD` = 0x3U }
AOI input signal indexes.
- enum `aoi_event_index_t` {
`kAoiEvent0` = 0x0U,
`kAoiEvent1` = 0x1U,
`kAoiEvent2` = 0x2U,
`kAoiEvent3` = 0x3U }
AOI event indexes, where an event is the collection of the four product terms (0, 1, 2, and 3) and the four signal inputs (A, B, C, and D).

Functions

- void `AOI_HAL_Init` (AOI_Type *base)
Initializes the AOI module to the reset state.
- void `AOI_HAL_Reset` (AOI_Type *base, `aoi_event_index_t` event)
Resets the configuration registers of a specific AOI event.

- void [AOI_HAL_SetSignalLogicUnit](#) (AOI_Type *base, [aoi_event_index_t](#) event, [aoi_product_term_t](#) productTerm, [aoi_input_signal_index_t](#) input, [aoi_input_config_t](#) config)
Defines the Boolean evaluation associated with the selected input in the selected product term of the desired event.
- [aoi_input_config_t](#) [AOI_HAL_GetSignalLogicUnit](#) (AOI_Type *base, [aoi_event_index_t](#) event, [aoi_product_term_t](#) productTerm, [aoi_input_signal_index_t](#) input)
Gets the Boolean evaluation associated with the selected input in the selected product term of the desired event.

5.2.2 Enumeration Type Documentation

5.2.2.1 enum aoi_status_t

Enumerator

- kStatus_AOI_Success* Success.
- kStatus_AOI_InvalidArgument* Invalid argument existed.
- kStatus_AOI_Failed* Execution failed.

5.2.2.2 enum aoi_input_config_t

Enumerator

- kAoiConfigLogicZero* Forces the input to logical zero.
- kAoiConfigInputSignal* Passes the input signal.
- kAoiConfigInvInputSignal* Inverts the input signal.
- kAoiConfigLogicOne* Forces the input to logical one.

5.2.2.3 enum aoi_product_term_t

Enumerator

- kAoiTerm0* Product term 0.
- kAoiTerm1* Product term 1.
- kAoiTerm2* Product term 2.
- kAoiTerm3* Product term 3.

5.2.2.4 enum aoi_input_signal_index_t

Enumerator

- kAoiInputA* Input configuration A.
- kAoiInputB* Input configuration B.

AOI HAL Driver

kAoiInputC Input configuration C.

kAoiInputD Input configuration D.

5.2.2.5 enum aoi_event_index_t

Enumerator

kAoiEvent0 Event 0 index.

kAoiEvent1 Event 1 index.

kAoiEvent2 Event 2 index.

kAoiEvent3 Event 3 index.

5.2.3 Function Documentation

5.2.3.1 void AOI_HAL_Init (AOI_Type * *base*)

This function initializes the module to the reset state. This state is defined in the chip Reference Manual, which is the power on reset value.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for AOI module. |
|-------------|---------------------------------------|

5.2.3.2 void AOI_HAL_Reset (AOI_Type * *base*, aoi_event_index_t *event*)

This function resets all product term inputs of a selected event to the reset values. This state is defined in the chip Reference Manual, which is the power on reset value.

Parameters

| | |
|--------------|---|
| <i>base</i> | Register base address for AOI module. |
| <i>event</i> | Event of AOI to be reset of type aoi_event_index_t. |

5.2.3.3 void AOI_HAL_SetSignalLogicUnit (AOI_Type * *base*, aoi_event_index_t *event*, aoi_product_term_t *productTerm*, aoi_input_signal_index_t *input*, aoi_input_config_t *config*)

This function defines the Boolean evaluation associated with the selected input in the selected product term of the desired event.

Parameters

| | |
|--------------------|--|
| <i>base</i> | Register base address for AOI module. |
| <i>event</i> | Number of the event which will be set of type <code>aoi_event_index_t</code> . |
| <i>productTerm</i> | The term which will be set of type <code>aoi_product_term_t</code> . |
| <i>input</i> | The input which will be set of type <code>aoi_input_signal_index_t</code> . |
| <i>config</i> | Selected input configuration of type <code>aoi_input_config_t</code> . |

5.2.3.4 `aoi_input_config_t` AOI_HAL_GetSignalLogicUnit (AOI_Type * *base*, *aoi_event_index_t event*, *aoi_product_term_t productTerm*, *aoi_input_signal_index_t input*)

This function returns the Boolean evaluation associated with the selected input in the selected product term of the desired event.

Parameters

| | |
|--------------------|--|
| <i>base</i> | Register base address for AOI module. |
| <i>event</i> | Number of the event which will be set of type <code>aoi_event_index_t</code> . |
| <i>productTerm</i> | The product term which will be set of type <code>aoi_product_term_t</code> . |
| <i>input</i> | The input which will be set of type <code>aoi_input_signal_index_t</code> . |

Returns

Selected input configuration of type `aoi_input_config_t`.

AOI Peripheral Driver

5.3 AOI Peripheral Driver

5.3.1 Overview

The section describes the programming interface of the AOI Peripheral driver.

5.3.2 Overview

The AOI peripheral driver configures the AOI (AND/OR/INVERT) module and handles the initialization and configuration of the AOI module.

5.3.3 Initialization

To initialize the AOI module, call the [AOI_DRV_Init\(\)](#) function. After initialization, the AOI module is set to a reset state.

```
// Initialize AOI module.  
AOI_DRV_Init(instance);
```

5.3.4 Event output configuration

The AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). The AOI is a highly programmable module for creating combinational boolean outputs for use as hardware triggers. Each selected input term in each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. To configure the selected AOI module event, call the API of the [AOI_DRV_SetEventLogic\(\)](#) function. To configure only one product term logic, call the [AOI_DRV_SetProductTermLogic\(\)](#) function. The AOI module does not support any special modes of operation.

5.3.5 Call diagram

1. Call the [AOI_DRV_Init\(\)](#) function to initialize AOI to a known state.
2. Optionally, call the [AOI_DRV_SetEventLogic\(\)](#) function to configure the Boolean evaluation in all product terms in one event. Use the configuration structure, [aoi_event_config_t](#) and number of the event, when calling this function.
3. Optionally, call the [AOI_DRV_SetProductTermLogic\(\)](#) function to configure the Boolean evaluation associated with all inputs in one product and in one event. Use the configuration structure, [aoi_product_term_config_t](#) and the product term and number of the event when calling this function.
4. Finally, the AOI works properly.

If you want to stop the AOI module, call the void [AOI_DRV_Deinit\(\)](#) function. This clears the AOI module configuration and disables the clock gate.

This is an example to initialize and configure the AOI driver for a possible use case. Because the AOI module function is directly connected with an XBAR (Inter-peripheral crossbar) module, other peripheral (PIT, CMP and XBAR) drivers are used to show full functionality of AOI module.

5.3.6.2.0.5.15 `aoi_input_config_t aoi_event_config_t::PT2BC`

5.3.6.2.0.5.16 `aoi_input_config_t aoi_event_config_t::PT2AC`

5.3.7 Function Documentation

5.3.7.1 `aoi_status_t AOI_DRV_Init (uint32_t instance)`

This function initializes AOI module. It configures all the AOI module inputs of all events to the reset state (`kAoiLogicZero`).

This is an example to initialize the AOI module:

```
status = AOI_DRV_Init();
switch (status)
{
    //...
}
```

AOI Peripheral Driver

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the AOI peripheral |
|-----------------|---|

Returns

kStatus_AOI_Success indicating successful initialization

5.3.7.2 aoi_status_t AOI_DRV_Deinit (uint32_t instance)

This function clears all configurations and shuts down the AOI module clock to reduce the power consumption.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the AOI peripheral |
|-----------------|---|

Returns

kStatus_AOI_Success indicating successful de-initialization

5.3.7.3 aoi_status_t AOI_DRV_ConfigEventLogic (uint32_t instance, aoi_event_index_t event, const aoi_event_config_t * eventConfigPtr)

This function configures an AOI event according to the aoiEventConfig structure. This function configures all inputs (A, B, C, and D) of all product terms (0, 1, 2, and 3) of a desired event. This is an example to set up the AOI Event structure:

```

aoi_event_config_t aoiEventConfig;

aoiEventConfig.PT0AC = kAoiConfigInputSignal;
aoiEventConfig.PT0BC = kAoiConfigLogicZero;
aoiEventConfig.PT0CC = kAoiConfigLogicZero;
aoiEventConfig.PT0DC = kAoiConfigLogicZero;

aoiEventConfig.PT1AC = kAoiConfigInvInputSignal;
aoiEventConfig.PT1BC = kAoiConfigLogicZero;
aoiEventConfig.PT1CC = kAoiConfigLogicZero;
aoiEventConfig.PT1DC = kAoiConfigInputSignal;

aoiEventConfig.PT2AC = kAoiConfigInputSignal;
aoiEventConfig.PT2BC = kAoiConfigInputSignal;
aoiEventConfig.PT2CC = kAoiConfigInputSignal;
aoiEventConfig.PT2DC = kAoiConfigLogicOne;

aoiEventConfig.PT3AC = kAoiConfigLogicOne;
aoiEventConfig.PT3BC = kAoiConfigLogicOne;
aoiEventConfig.PT3CC = kAoiConfigLogicOne;
aoiEventConfig.PT3DC = kAoiConfigLogicOne;

```

```

aoi_status_t status;
// In the function call below, the value of "2" indicates event #2 is being used.
status = AOI_DRV_ConfigEventLogic(0, 2, &aoiEventConfig);
switch (status)
{
    //...
}

```

Parameters

| | |
|-----------------------|---|
| <i>instance</i> | The instance number of the AOI peripheral |
| <i>event</i> | Event which will be configured of type <code>aoi_event_index_t</code> . |
| <i>eventConfigPtr</i> | Pointer to type <code>aoi_event_config_t</code> structure. The user is responsible to fill out the members of this structure and pass the pointer to this function. |

Returns

An error code or `kStatus_AOI_Success`.

5.3.7.4 `aoi_status_t AOI_DRV_ConfigProductTermLogic (uint32_t instance, aoi_event_index_t event, aoi_product_term_t productTerm, const aoi_product_term_config_t * productTermConfigPtr)`

This function configures an AOI module product terms for a specific event. The user has to select the event and the product term which is configured and fill the `AoiProductTermConfig` configuration structure.

Example:

```

aoi_product_term_config_t productTermConfigStruct;
aoi_status_t status;

productTermConfigStruct.PTAC = kAoiConfigLogicZero;
productTermConfigStruct.PTBC = kAoiConfigInputSignal;
productTermConfigStruct.PTCC = kAoiConfigInvInputSignal;
productTermConfigStruct.PTDC = kAoiConfigLogicOne;

// Configure product term 1 of event 3
status = AOI_DRV_ConfigProductTermLogic(0, 3,
    kAoiTerm1, &productTermConfigStruct);
switch (status)
{
    //...
}

```

AOI Peripheral Driver

Parameters

| | |
|------------------------------|--|
| <i>instance</i> | The instance number of the AOI peripheral |
| <i>event</i> | Event which will be configured of type <code>aoi_event_index_t</code> . |
| <i>productTerm</i> | Product term which will be configured of type <code>aoi_product_term_t</code> . |
| <i>productTerm-ConfigPtr</i> | Pointer to type <code>aoi_product_term_config_t</code> structure. The user is responsible to fill out the members of this structure and pass the pointer to this function. |

Returns

An error code or `kStatus_AOI_Success`.

5.3.8 Variable Documentation

5.3.8.1 `AOI_Type* const g_aoiBase[]`

Chapter 6 C90TFS Flash Driver

6.1 Overview

The Kinetis SDK provides the C90TFS Flash driver of Kinetis devices with the C90TFS Flash module inside. The C90TFS/FTFx SSD provides general APIs to handle specific operations on C90TFS/FTFx Flash module. The user can use those APIs directly in the application. In addition, it provides internal functions called by the driver. Although these functions are not meant to be called from the user's application directly, the APIs can still be used.

The C90TFS/FTFx SSD provides the following features:

1. Drivers released in source code format to provide compiler-independent supporting for non-debug-mode embedded applications.
2. Each driver function is independent. Therefore, the end user can choose the function subset to meet their particular needs.
3. Position-independent and ROM-able.
4. Concurrency support via callback.

Important Note

1. The DebugEnable field of [FLASH_SSD_CONFIG](#) structure allows the user to use this driver in the background debug mode without returning to the caller function, but returning to debug mode instead. To enable this feature, DebugEnable must be set to TRUE and macro C90TFS_ENABLE_DEBUG must be set to 1.
2. To use callback in the application, this callback function must not be placed in the same Flash block in which a program/erase operation occurs to avoid the RWW error.
3. To suspend the sector erase operation for a simple method, invoke the FlashEraseSuspend function within callback of FlashEraseSector. In this case, the FlashEraseSuspend must not be placed in the same block in which the Flash erase sector command is going on.
4. FlashCommandSequence, FlashSuspend and FlashResume should be executed from RAM or different Flash blocks which are targeted for writing to avoid the RWW error.
5. To guarantee the correct execution of this driver, the Flash cache in the Flash memory controller module should be disabled before invoking any API. The standard demo included in the release package provides the code part to disable/enable the Flash cache.

Data Structures

- struct [PFLASH_SSD_CONFIG](#)
Flash SSD Configuration Structure. [More...](#)

Macros

- #define [SET_FLASH_INT_BITS](#)(ftfxRegBase, value)

Overview

- Sets the Flash interrupt enable bits in the FCNFG register.
- #define `GET_FLASH_INT_BITS(ftfxRegBase)`
Returns the Flash interrupt enable bits in the FCNFG register.

C90TFS Flash configuration

- #define `ENDIANNESS LITTLE_ENDIAN`
Endianness.
- #define `CPU_CORE ARM_CORTEX_M`
CPU core.

Complete swap mode.

C90TFS Flash driver APIs

- uint32_t [RelocateFunction](#) (uint32_t dest, uint32_t size, uint32_t src)
Relocates a function to RAM address.
- uint32_t [FlashInit](#) (PFLASH_SSD_CONFIG pSSDConfig)
Initializes Flash.
- uint32_t [FlashCommandSequence](#) (PFLASH_SSD_CONFIG pSSDConfig)
Flash command sequence.
- uint32_t [PFlashGetProtection](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t *protectStatus)
P-Flash get protection.
- uint32_t [PFlashSetProtection](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t protectStatus)
P-Flash set protection.
- uint32_t [FlashGetSecurityState](#) (PFLASH_SSD_CONFIG pSSDConfig, uint8_t *securityState)
Flash get security state.
- uint32_t [FlashSecurityBypass](#) (PFLASH_SSD_CONFIG pSSDConfig, uint8_t *keyBuffer, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash security bypass.
- uint32_t [FlashEraseAllBlock](#) (PFLASH_SSD_CONFIG pSSDConfig, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash erase all Blocks.
- uint32_t [FlashEraseAllBlockUnsecure](#) (PFLASH_SSD_CONFIG pSSDConfig, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash erase all Blocks unsecure.
- uint32_t [FlashVerifyAllBlock](#) (PFLASH_SSD_CONFIG pSSDConfig, uint8_t marginLevel, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash verify all Blocks.
- uint32_t [FlashEraseSector](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash erase sector.
- uint32_t [FlashVerifySection](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint16_t number, uint8_t marginLevel, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash verify sector.
- uint32_t [FlashEraseSuspend](#) (PFLASH_SSD_CONFIG pSSDConfig)
Flash erase suspend.
- uint32_t [FlashEraseResume](#) (PFLASH_SSD_CONFIG pSSDConfig)
Flash erase resume.
- uint32_t [FlashReadOnce](#) (PFLASH_SSD_CONFIG pSSDConfig, uint8_t recordIndex, uint8_t *pDataArray, uint32_t size, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash read once.
- uint32_t [FlashProgramOnce](#) (PFLASH_SSD_CONFIG pSSDConfig, uint8_t recordIndex, uint8_t *pDataArray, uint32_t size, [PFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)

Overview

- Flash program once.*

 - uint32_t [FlashReadResource](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t *pDataArray, uint8_t resourceSelectCode, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash read resource.*

 - uint32_t [FlashProgram](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t *pData, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash program.*

 - uint32_t [FlashProgramCheck](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t *pExpectedData, uint32_t *pFailAddr, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash program check.*

 - uint32_t [FlashCheckSum](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint32_t *pSum)
- Calculates check sum.*

 - uint32_t [FlashProgramSection](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint16_t number, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash program part.*

 - 32_t [FlashEraseBlock](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash erase block.*

 - uint32_t [FlashVerifyBlock](#) (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
- Flash verify block.*

Return Code Definition for FTFx SSD

- #define [FTFx_OK](#) 0x0000U
Function executes successfully.
- #define [FTFx_ERR_MGSTAT0](#) 0x0001U
MGSTAT0 bit is set in the FSTAT register.
- #define [FTFx_ERR_PVIOL](#) 0x0010U
Protection violation is set in FSTAT register.
- #define [FTFx_ERR_ACCERR](#) 0x0020U
Access error is set in the FSTAT register.
- #define [FTFx_ERR_CHANGEPROT](#) 0x0100U
Cannot change protection status.
- #define [FTFx_ERR_NOEEE](#) 0x0200U
FlexRAM is not set for EEPROM use.
- #define [FTFx_ERR_EFLASHONLY](#) 0x0400U
FlexNVM is set for full EEPROM backup.
- #define [FTFx_ERR_RAMRDY](#) 0x0800U
Programming acceleration RAM is not available.
- #define [FTFx_ERR_RANGE](#) 0x1000U
Address is out of the valid range.
- #define [FTFx_ERR_SIZE](#) 0x2000U
Misaligned size.
- #define [FTFx_ERR_NOFAC](#) 0x4000U
No FAC feature

Flash security status

- #define `FLASH_NOT_SECURE` 0x01U
Flash currently not in secure state.
- #define `FLASH_SECURE_BACKDOOR_ENABLED` 0x02U
Flash is secured and backdoor key access enabled.
- #define `FLASH_SECURE_BACKDOOR_DISABLED` 0x04U
Flash is secured and backdoor key access disabled.

Null Callback function definition

- #define `NULL_CALLBACK` ((PCALLBACK)0xFFFFFFFF)
Null callback.
- #define `NULL_SWAP_CALLBACK` ((PFLASH_SWAP_CALLBACK)0xFFFFFFFF)
Null swap callback.

Type definition for flash driver

- typedef void(* `PCALLBACK`)(void)
Call back function pointer data type.
- typedef bool(* `PFLASH_SWAP_CALLBACK`)(uint8_t function)
Swap call back function pointer data type.
- typedef uint32_t(* `PFLASHCOMMANDSEQUENCE`)(PFLASH_SSD_CONFIG pSSDConfig)
FlashCommandSequence function pointer.
- typedef uint32_t(* `PFLASHINIT`)(PFLASH_SSD_CONFIG pSSDConfig)
FlashInit function pointer.
- typedef uint32_t(* `PFLASHGETPROTECTION`)(PFLASH_SSD_CONFIG pSSDConfig, uint32_t *protectStatus)
PFlashGetProtection function pointer.
- typedef uint32_t(* `PFLASHSETPROTECTION`)(PFLASH_SSD_CONFIG pSSDConfig, uint32_t protectStatus)
PFlashSetProtection function pointer.
- typedef uint32_t(* `PFLASHFACGETXAPROTECTION`)(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *protectStatus, uint8_t *numberOfSegments, uint32_t *segmentSize)
PFlashFacGetXAProtection function pointer.
- typedef uint32_t(* `PFLASHFACGETSAPROTECTION`)(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *protectStatus, uint8_t *numberOfSegments, uint32_t *segmentSize)
PFlashFacGetSAProtection function pointer.
- typedef uint32_t(* `PFLASHGETSECURITYSTATE`)(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *securityState)
FlashGetSecurityState function pointer.
- typedef uint32_t(* `PFLASHSECURITYBYPASS`)(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *keyBuffer, `PFLASHCOMMANDSEQUENCE` pFlashCommandSequence)
FlashSecurityByPass function pointer.
- typedef uint32_t(* `PFLASHERASEALLBLOCK`)(PFLASH_SSD_CONFIG pSSDConfig, `PFLASHCOMMANDSEQUENCE` pFlashCommandSequence)
FlashEraseAllBlock function pointer.
- typedef uint32_t(* `PFLASHERASEALLBLOCKUNSECURE`)(PFLASH_SSD_CONFIG pSSDConfig, `PFLASHCOMMANDSEQUENCE` pFlashCommandSequence)
FlashEraseAllBlockUnsecure function pointer.

Overview

- typedef uint32_t(* [pFLASHERASEBLOCK](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashEraseBlock function pointer.
- typedef uint32_t(* [pFLASHERASESECTOR](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashEraseSector function pointer.
- typedef uint32_t(* [pFLASHERASESUSPEND](#))(PFLASH_SSD_CONFIG pSSDConfig)
FlashEraseSuspend function pointer.
- typedef uint32_t(* [pFLASHERASERESUME](#))(PFLASH_SSD_CONFIG pSSDConfig)
FlashEraseResume function pointer.
- typedef uint32_t(* [pFLASHPROGRAMSECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint16_t number, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashProgramSection function pointer.
- typedef uint32_t(* [pFLASHCHECKSUM](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint32_t *pSum)
FlashChecksum function pointer.
- typedef uint32_t(* [pFLASHVERIFYALLBLOCK](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashVerifyAllBlock function pointer.
- typedef uint32_t(* [pFLASHVERIFYBLOCK](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
Flash verify block.
- typedef uint32_t(* [pFLASHVERIFYSECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint16_t number, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashVerifySection function pointer.
- typedef uint32_t(* [pFLASHREADONCE](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *pDataArray, uint32_t size, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashReadOnce function pointer.
- typedef uint32_t(* [pFLASHPROGRAMONCE](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *pDataArray, uint32_t size, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashProgramOnce function pointer.
- typedef uint32_t(* [pFLASHPROGRAMCHECK](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t *pExpectedData, uint32_t *pFailAddr, uint8_t marginLevel, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashProgramCheck function pointer.
- typedef uint32_t(* [pFLASHREADRESOURCE](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t *pDataArray, uint8_t resourceSelectCode, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashReadResource function pointer.
- typedef uint32_t(* [pFLASHPROGRAM](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t *pData, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
FlashProgram function pointer.
- typedef uint32_t(* [pPFLASHSWAPCTRL](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t addr, uint8_t swapcmd, uint8_t *pCurrentSwapMode, uint8_t *pCurrentSwapBlockStatus, uint8_t *pNextSwapBlockStatus, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
PFflashSwapCtrl function pointer.
- typedef uint32_t(* [pFLASHSWAP](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t flashAddress, [PFLASH_SWAP_CALLBACK](#) pSwapCallback, [pFLASHCOMMANDSEQUENCE](#)

- pFlashCommandSequence)
 - PFlashSwap function pointer.*
- typedef uint32_t(* [pDFLASHGETPROTECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *protectStatus)
 - DFlashGetProtection function pointer.*
- typedef uint32_t(* [pDFLASHSETPROTECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t protectStatus)
 - DFlashSetProtection function pointer.*
- typedef uint32_t(* [pEERAMGETPROTECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t *protectStatus)
 - EERAMGetProtection function pointer.*
- typedef uint32_t(* [pEERAMSETPROTECTION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t protectStatus)
 - EERAMSetProtection function pointer.*
- typedef uint32_t(* [pDEFLASHPARTITION](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t EEDataSizeCode, uint8_t DEPartitionCode, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
 - DEFlashParition function pointer.*
- typedef uint32_t(* [pSETEEEENABLE](#))(PFLASH_SSD_CONFIG pSSDConfig, uint8_t EEEEnable, [pFLASHCOMMANDSEQUENCE](#) pFlashCommandSequence)
 - SetEEEEEnable function pointer.*
- typedef uint32_t(* [pEEEEWRITE](#))(PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t *pData)
 - EEEWrite function pointer.*

6.2 Data Structure Documentation

6.2.1 struct FLASH_SSD_CONFIG

The structure includes the static parameters for C90TFS/FTFx which are device-dependent. The user should correctly initialize the fields including ftxRegBase, PFlashBlockBase, PFlashBlockSize, DFlashBlockBase, EERAMBlockBase, DebugEnable and Callback before passing the structure to SSD functions. The rest of parameters such as DFlashBlockSize, and EEEBlockSize will be initialized in [FlashInit\(\)](#) automatically. The pointer to Callback has to be initialized either for null callback or a valid call back function.

Data Fields

- uint32_t [ftxRegBase](#)
 - The register base address of C90TFS/FTFx.*
- uint32_t [PFlashBase](#)
 - The base address of P-Flash memory.*
- uint32_t [PFlashSize](#)
 - The size in byte of P-Flash memory.*
- uint32_t [DFlashBase](#)
 - For FlexNVM device, this is the base address of D-Flash memory (FlexNVM memory); For non-FlexNVM device, this field is unused.*

Macro Definition Documentation

- `uint32_t DFlashSize`
For FlexNVM device, this is the size in byte of area which is used as D-Flash from FlexNVM memory; For non-FlexNVM device, this field is unused.
- `uint32_t EERAMBase`
The base address of FlexRAM (for FlexNVM device) or acceleration RAM memory (for non-FlexNVM device)
- `uint32_t EEESize`
For FlexNVM device, this is the size in byte of EEPROM area which was partitioned from FlexRAM; For non-FlexNVM device, this field is unused.
- `bool DebugEnable`
Background debug mode enable.
- `PCALLBACK Callback`
Call back function to service the time critical events.

6.3 Macro Definition Documentation

6.3.1 #define BYTE2WORD(x) (x)

Two address types are only different in DSC devices. In Kintistis devices, they are the same

6.3.2 #define WORD2BYTE(x) (x)

Two address types are only different in DSC devices. In Kintistis devices, they are the same

6.3.3 #define SET_FLASH_INT_BITS(ftxRegBase, value)

Value:

```
REG_WRITE((ftfxRegBase) + FTFx_SSD_FCENFG_OFFSET, \
          ((value)&(FTFx_SSD_FCENFG_CCIE | FTFx_SSD_FCENFG_RDCOLLIE)))
```

Parameters

| | |
|--------------------|---|
| <i>ftfxRegBase</i> | Specifies register base address of the Flash module |
| <i>value</i> | The bit map value (0: disabled, 1 enabled) . The numbering is marked from 0 to 7 where bit 0 is the least significant bit. Bit 7 is corresponding to command complete interrupt. Bit 6 is corresponding to read collision error interrupt. |

6.3.4 #define GET_FLASH_INT_BITS(*ftfxRegBase*)

Value:

```
REG_READ((ftfxRegBase) + FTFx_SSD_FCENFG_OFFSET) &\
        (FTFx_SSD_FCENFG_CCIE | FTFx_SSD_FCENFG_RDCOLLIE)
```

Parameters

| | |
|--------------------|--|
| <i>ftfxRegBase</i> | Specifies register base address of the Flash module. |
|--------------------|--|

6.3.5 #define FTFx_ERR_MGSTAT0 0x0001U

Possible causes:

MGSTAT0 bit in FSTAT register is set. Refer to corresponding command description of each API on reference manual to get detail reasons

Solution:

Hardware error

6.3.6 #define FTFx_ERR_PVIOL 0x0010U

Possible causes:

FPVIOL bit in FSTAT register is set. Refer to corresponding command description of each API on reference manual to get detail reasons

Solution:

The flash location targeted to program/erase operation must be unprotected. Swap indicator must not be programmed/erased except in Update or Update-Erase state.

6.3.7 #define FTFx_ERR_ACCERR 0x0020U

Possible causes:

ACCERR bit in FSTAT register is set. Refer to corresponding command description of each API on reference manual to get detail reasons.

Solution:

Provide valid input parameters for each API according to specific flash module.

Macro Definition Documentation

6.3.8 #define FTFx_ERR_CHANGEPROT 0x0100U

Possible causes:

Violates protection transition.

Solution:

In NVM normal mode, protection size cannot be decreased. Therefore, the only increasing protection size is permitted if the device is operating in this mode.

6.3.9 #define FTFx_ERR_NOEEE 0x0200U

Possible causes:

User accesses to EEPROM operation but there is no EEPROM backup enabled.

Solution:

Need to enable EEPROM by partitioning FlexNVM to have EEPROM backup and/or enable it by SetEE-Enable API.

6.3.10 #define FTFx_ERR_EFLASHONLY 0x0400U

Possible causes:

User accesses to D-Flash operation but there is no D-Flash on FlexNVM.

Solution:

Need to partition FlexNVM to have D-Flash.

6.3.11 #define FTFx_ERR_RAMRDY 0x0800U

Possible causes:

User invokes flash program part command but FlexRam is being set for EEPROM emulation. Solution:

Need to set FlexRam as traditional Ram by SetEEEnable API.

6.3.12 #define FTFx_ERR_RANGE 0x1000U

Possible causes:

The size or destination provided by user makes start address or end address out of valid range.

Solution:

Make sure the destination and (destination + size) within valid address range.

6.3.13 #define FTFx_ERR_SIZE 0x2000U

Possible causes:

The size provided by user is misaligned.

Solution:

Size must be an aligned value according to specific constrain of each API.

6.3.14 #define FTFx_ERR_NOFAC 0x4000U

Possible causes:

User invokes get FAC XA or SA protection command but there is not FAC on FTFA/FTFE/FTFL modules.

Solution:

Do not invoke FAC related APIs when it is unavailable.

6.4 Function Documentation

6.4.1 uint32_t RelocateFunction (uint32_t dest, uint32_t size, uint32_t src)

This function provides a facility to relocate a function in RAM.

Parameters

| | |
|-------------|---|
| <i>dest</i> | Destination address where you want to place the function. |
| <i>size</i> | Size of the function |
| <i>src</i> | Address of the function will be relocated |

Returns

Relocated address of the function .

6.4.2 uint32_t FlashInit (PFLASH_SSD_CONFIG pSSDConfig)

This API initializes Flash module by clearing status error bit and reporting the memory configuration via SSD configuration structure.

Function Documentation

Parameters

| | |
|-------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
|-------------------|--|

Returns

Successful completion (FTFx_OK)

6.4.3 uint32_t FlashCommandSequence (PFLASH_SSD_CONFIG pSSDConfig)

This API is used to perform command write sequence on Flash. It is internal function, called by driver APIs only.

Parameters

| | |
|-------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
|-------------------|--|

Returns

Successful completion (FTFx_OK)

Failed in Flash command execution (FTFx_ERR_ACCERR, FTFx_ERR_PVIOL, FTFx_ERR_M-GSTAT0)

6.4.4 uint32_t PFlashGetProtection (PFLASH_SSD_CONFIG pSSDConfig, uint32_t * protectStatus)

This API retrieves the current P-Flash protection status. Considering the time consumption for getting protection is very low and even can be ignored. It is not necessary to utilize the Callback function to support the time-critical events.

Parameters

| | |
|----------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>protectStatus</i> | To return the current value of the P-Flash Protection. Each bit is corresponding to protection of 1/32 of the total P-Flash. The least significant bit is corresponding to the lowest address area of P-Flash. The most significant bit is corresponding to the highest address area of P-Flash and so on. There are two possible cases as below: <ul style="list-style-type: none"> • 0: this area is protected. • 1: this area is unprotected. |

Returns

Successful completion (FTFx_OK)

6.4.5 uint32_t PFlashSetProtection (PFLASH_SSD_CONFIG pSSDConfig, uint32_t protectStatus)

This API sets the P-Flash protection to the intended protection status. Setting P-Flash protection status is subject to a protection transition restriction. If there is a setting violation, it returns an error code and the current protection status won't be changed.

Parameters

| | |
|----------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>protectStatus</i> | The expected protect status user wants to set to P-Flash protection register. Each bit is corresponding to protection of 1/32 of the total P-Flash. The least significant bit is corresponding to the lowest address area of P-Flash. The most significant bit is corresponding to the highest address area of P-Flash, and so on. There are two possible cases as shown below: <ul style="list-style-type: none"> • 0: this area is protected. • 1: this area is unprotected. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_CHANGEPROT)

6.4.6 uint32_t FlashGetSecurityState (PFLASH_SSD_CONFIG pSSDConfig, uint8_t * securityState)

This API retrieves the current Flash security status, including the security enabling state and the back door key enabling state.

Parameters

| | |
|-------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
|-------------------|--|

Function Documentation

| | |
|----------------------|---|
| <i>securityState</i> | To return the current security status code. FLASH_NOT_SECURE (0x01): Flash currently not in secure state; FLASH_SECURE_BACKDOOR_ENABLED (0x02): Flash is secured and back door key access enabled; FLASH_SECURE_BACKDOOR_DISABLED (0x04): Flash is secured and back door key access disabled. |
|----------------------|---|

Returns

Successful completion (FTFx_OK)

6.4.7 `uint32_t FlashSecurityBypass (PFLASH_SSD_CONFIG pSSDConfig, uint8_t * keyBuffer, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)`

This API un-secures the device by comparing the user's provided back door key with the ones in the Flash Configuration Field. If they are matched, the security is released. Otherwise, an error code is returned.

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>keyBuffer</i> | Point to the user buffer containing the back door key. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)
Error value (FTFx_ERR_ACCERR)

6.4.8 `uint32_t FlashEraseAllBlock (PFLASH_SSD_CONFIG pSSDConfig, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)`

This API erases all Flash memory, initializes the FlexRAM, verifies all memory contents, and then releases the MCU security.

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)
 Error value (FTFx_ERR_PVIOL, FTFx_ERR_MGSTAT0, FTFx_ERR_ACCERR)

6.4.9 uint32_t FlashEraseAllBlockUnsecure (PFLASH_SSD_CONFIG *pSSDConfig*, pFLASHCOMMANDSEQUENCE *pFlashCommandSequence*)

This API erases all Flash memory, initializes the FlexRAM, verifies all memory contents, program security byte to unsecure state, and then releases MCU security. Note: This API only applies to limited targets, please refer to FTFA/FTFE/FTFL chapter and check the validity of this API.

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)
 Error value (FTFx_ERR_MGSTAT0, FTFx_ERR_ACCERR)

6.4.10 uint32_t FlashVerifyAllBlock (PFLASH_SSD_CONFIG *pSSDConfig*, uint8_t *marginLevel*, pFLASHCOMMANDSEQUENCE *pFlashCommandSequence*)

This function checks to see if the P-Flash and/or D-Flash, EEPROM backup area, and D-Flash IFR have been erased to the specified read margin level, if applicable, and releases security if the readout passes.

Function Documentation

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>marginLevel</i> | Read Margin Choice as follows: marginLevel = 0x0: use the Normal read level marginLevel = 0x1: use the User read marginLevel = 0x2: use the Factory read |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_MGSTAT0, FTFx_ERR_ACCERR)

6.4.11 **uint32_t FlashEraseSector (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)**

This API erases one or more sectors in P-Flash or D-Flash memory. This API always returns FTFx_OK if size provided by the user is zero regardless of the input validation.

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Address in the first sector to be erased. |
| <i>size</i> | Size to be erased in bytes. It is used to determine number of sectors to be erased. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_MGSTAT0, FTFx_ERR_ACCERR, FTFx_ERR_PVIOL, FTFx_ERR_SIZE)

6.4.12 `uint32_t FlashVerifySection (PFLASH_SSD_CONFIG pSSD-Config, uint32_t dest, uint16_t number, uint8_t marginLevel, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)`

This API checks if a part of the P-Flash or the D-Flash memory is erased to the specified read margin level.

Function Documentation

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended verify operation. |
| <i>number</i> | Number of alignment unit to be verified. Refer to corresponding reference manual to get correct information of alignment constrain. |
| <i>marginLevel</i> | Read Margin Choice as follows: marginLevel = 0x0: use Normal read level marginLevel = 0x1: use the User read marginLevel = 0x2: use the Factory read |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_MGSTAT0, FTFx_ERR_ACCERR)

6.4.13 uint32_t FlashEraseSuspend (PFLASH_SSD_CONFIG pSSDConfig)

This API is used to suspend a current operation of Flash erase sector command. This function must be located in RAM memory or different Flash blocks which are targeted for writing to avoid the RWW error.

Parameters

| | |
|-------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
|-------------------|--|

Returns

Successful completion (FTFx_OK)

6.4.14 uint32_t FlashEraseResume (PFLASH_SSD_CONFIG pSSDConfig)

This API is used to resume a previous suspended operation of Flash erase sector command This function must be located in RAM memory or different Flash blocks which are targeted for writing to avoid RWW error.

Parameters

| | |
|-------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
|-------------------|--|

Returns

Successful completion (FTFx_OK)

6.4.15 uint32_t FlashReadOnce (PFLASH_SSD_CONFIG pSSDConfig, uint8_t recordIndex, uint8_t * pDataArray, uint32_t size, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API is used to read out a reserved 64 byte field located in the P-Flash IFR via given number of record. See the corresponding reference manual to get the correct value of this number.

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>recordIndex</i> | The record index will be read. It can be from 0x0 to 0x7 or other range according to specific derivative. |
| <i>size</i> | Byte count of data to be read. The value of size should be 4 or 8 according to specific derivative. |
| <i>pDataArray</i> | Pointer to the array to return the data read by the read once command. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)
 Error value (FTFx_ERR_ACCERR)

6.4.16 uint32_t FlashProgramOnce (PFLASH_SSD_CONFIG pSSDConfig, uint8_t recordIndex, uint8_t * pDataArray, uint32_t size, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API is used to program to a reserved 64 byte field located in the P-Flash IFR via given number of record. See the corresponding reference manual to get correct value of this number.

Function Documentation

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>recordIndex</i> | The record index will be read. It can be from 0x0 to 0x7 or other range according to specific derivative. |
| <i>pdataArray</i> | Pointer to the array from which data will be taken for program once command. |
| <i>size</i> | Byte count of data to be programmed. The value of size should be 4 or 8 according to specific derivative. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_ACCERR,FTFx_ERR_MGSTAT0)

6.4.17 `uint32_t FlashReadResource (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t * pdataArray, uint8_t resourceSelectCode, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)`

This API is used to read data from special purpose memory in Flash memory module including P-Flash IFR, swap IFR, D-Flash IFR space and version ID.

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended read operation. |
| <i>pdataArray</i> | Pointer to the data returned by the read resource command. |
| <i>resourceSelect-Code</i> | Read resource select code: 0 : Flash IFR 1: Version ID |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

- Successful completion (FTFx_OK)
- Error value (FTFx_ERR_ACCERR)

6.4.18 uint32_t FlashProgram (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t * pData, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API is used to program 4 consecutive bytes (for program long word command) and 8 consecutive bytes (for program phrase command) on P-Flash or D-Flash block. This API always returns FTFx_OK if size provided by user is zero regardless of the input validation

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended program operation. |
| <i>size</i> | Size in byte to be programmed |
| <i>pData</i> | Pointer of source address from which data has to be taken for program operation. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

- Successful completion (FTFx_OK)
- Error value (FTFx_ERR_ACCERR, FTFx_ERR_PVIOL, FTFx_ERR_SIZE, FTFx_ERR_MGSTAT0)

6.4.19 uint32_t FlashProgramCheck (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint8_t * pExpectedData, uint32_t * pFailAddr, uint8_t marginLevel, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API tests a previously programmed P-Flash or D-Flash long word to see if it reads correctly at the specified margin level. This API always returns FTFx_OK if size provided by user is zero regardless of the input validation

Function Documentation

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended program check operation. |
| <i>size</i> | Size in byte to check accuracy of program operation |
| <i>pExpectedData</i> | The pointer to the expected data. |
| <i>pFailAddr</i> | Returned the first aligned failing address. |
| <i>marginLevel</i> | Read margin choice as follows: marginLevel = 0x1: read at User margin 1/0 level. marginLevel = 0x2: read at Factory margin 1/0 level. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_ACCERR, FTFx_ERR_MGSTAT0)

6.4.20 uint32_t FlashChecksum (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint32_t size, uint32_t * pSum)

This API performs 32 bit sum of each byte data over a specified Flash memory range without carry which provides rapid method for checking data integrity. The callback time period of this API is determined via FLASH_CALLBACK_CS macro in the SSD_FTFx_Common.h which is used as a counter value for the CallBack() function calling in this API. This value can be changed as per the user requirement. User can change this value to obtain the maximum permissible callback time period. This API always returns FTFx_OK if size provided by user is zero regardless of the input validation.

Parameters

| | |
|-------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address of the Flash range to be summed |
| <i>size</i> | Size in byte of the Flash range to be summed |
| <i>pSum</i> | To return the sum value |

Returns

- Successful completion (FTFx_OK)
- Error value (FTFx_ERR_RANGE)

6.4.21 uint32_t FlashProgramSection (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint16_t number, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API will program the data found in the Section Program Buffer to previously erased locations in the Flash memory. Data is preloaded into the Section Program Buffer by writing to the acceleration Ram and FlexRam while it is set to function as a RAM. The Section Program Buffer is limited to the value of FlexRam divides by a ratio. Refer to the associate reference manual to get correct value of this ratio. For derivatives including swap feature, the swap indicator address is encountered during FlashProgramSection, it is bypassed without setting FPVIOL but the content are not be programmed. In addition, the content of source data used to program to swap indicator will be re-initialized to 0xFF after completion of this command.

Parameters

| | |
|--------------------------------|--|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended program operation. |
| <i>number</i> | Number of alignment unit to be programmed. Refer to associate reference manual to get correct value of this alignment constrain. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

- Successful completion (FTFx_OK)
- Error value (FTFx_ERR_ACCERR, FTFx_ERR_PVIOL, FTFx_ERR_MGSTAT0, FTFx_ERR_R-AMRDY)

6.4.22 uint32_t FlashEraseBlock (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API erases all addresses in an individual P-Flash or D-Flash block. For the derivatives including multiply logical P-Flash or D-Flash blocks, this API erases a single block in a single call.

Function Documentation

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended erase operation. |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_ACCERR, FTFx_ERR_PVIOL, FTFx_ERR_MGSTAT0)

6.4.23 uint32_t FlashVerifyBlock (PFLASH_SSD_CONFIG pSSDConfig, uint32_t dest, uint8_t marginLevel, pFLASHCOMMANDSEQUENCE pFlashCommandSequence)

This API checks to see if an entire P-Flash or D-Flash block has been erased to the specified margin level. For the derivatives including multiply logical P-Flash or D-Flash blocks, this API erases a single block in a single call.

Parameters

| | |
|--------------------------------|---|
| <i>pSSDConfig</i> | The SSD configuration structure pointer. |
| <i>dest</i> | Start address for the intended verify operation. |
| <i>marginLevel</i> | Read Margin Choice as follows: marginLevel = 0x0: use Normal read level margin-Level = 0x1: use the User read marginLevel = 0x2: use the Factory read |
| <i>pFlash-Command-Sequence</i> | : Pointer to the Flash command sequence function. |

Returns

Successful completion (FTFx_OK)

Error value (FTFx_ERR_ACCERR, FTFx_ERR_MGSTAT0)

Chapter 7

12-bit Cyclic Analog-to-Digital Converter (CADC)

7.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the 12-bit Cyclic Analog-to-Digital Converter (CADC) block of Kinetis devices.

Modules

- [CADC HAL Driver](#)
- [CADC Peripheral Driver](#)

CADC HAL Driver

7.2 CADC HAL Driver

7.2.1 Overview

This section describes the programming interface of the CADC HAL driver.

Data Structures

- struct `cadc_controller_config_t`
Defines a structure to configure the CyclicADC module during initialization. [More...](#)
- struct `cadc_converter_config_t`
Defines a structure to configure each converter in the CyclicADC module. [More...](#)
- struct `cadc_chn_config_t`
Defines a structure to configure each input channel. [More...](#)
- struct `cadc_slot_config_t`
Defines a structure to configure each slot. [More...](#)

Enumerations

- enum `cadc_status_t` {
`kStatus_CADC_Success = 0U,`
`kStatus_CADC_InvalidArgument = 1U,`
`kStatus_CADC_Failed = 2U }`
CADC status return codes.
- enum `cadc_diff_chn_t` {
`kCAdcDiffChnANA0_1 = 0U,`
`kCAdcDiffChnANA2_3 = 1U,`
`kCAdcDiffChnANA4_5 = 2U,`
`kCAdcDiffChnANA6_7 = 3U,`
`kCAdcDiffChnANB0_1 = 4U,`
`kCAdcDiffChnANB2_3 = 5U,`
`kCAdcDiffChnANB4_5 = 6U,`
`kCAdcDiffChnANB6_7 = 7U }`
Defines the type of enumerating ADC differential channel pair.
- enum `cadc_chn_sel_mode_t` {
`kCAdcChnSelN = 0U,`
`kCAdcChnSelP = 1U,`
`kCAdcChnSelBoth = 2U }`
Defines the type of enumerating ADC channel in a differential pair.
- enum `cadc_scan_mode_t` {
`kCAdcScanOnceSequential = 0U,`
`kCAdcScanOnceParallel = 1U,`
`kCAdcScanLoopSequential = 2U,`
`kCAdcScanLoopParallel = 3U,`
`kCAdcScanTriggeredSequential = 4U,`

`kCAdcScanTriggeredParalled = 5U }`

Defines the type of enumerating ADC converter's scan mode.

- enum `cadc_zero_crossing_mode_t` {
`kCAdcZeroCrossingDisable = 0U,`
`kCAdcZeroCrossingAtRisingEdge = 1U,`
`kCAdcZeroCrossingAtFallingEdge = 2U,`
`kCAdcZeroCrossingAtBothEdge = 3U }`

Defines the type to enumerate the zero crossing detection mode for each slot.

- enum `cadc_gain_mode_t` {
`kCAdcSGainBy1 = 0U,`
`kCAdcSGainBy2 = 1U,`
`kCAdcSGainBy4 = 2U }`

Defines the type to enumerate the amplification mode for each slot.

- enum `cadc_conv_speed_mode_t` {
`kCAdcConvClkLimitBy6_25MHz = 0U,`
`kCAdcConvClkLimitBy12_5MHz = 1U,`
`kCAdcConvClkLimitBy18_75MHz = 2U,`
`kCAdcConvClkLimitBy25MHz = 3U }`

Defines the type to enumerate the speed mode for each converter.

- enum `cadc_dma_trigger_src_t` {
`kCAdcDmaTriggeredByEndOfScan = 0U,`
`kCAdcDmaTriggeredByConvReady = 1U }`

Defines the type of DMA trigger source for each converter.

Functions

- void `CADC_HAL_Init` (ADC_Type *base)
Initializes all ADC registers to a known state.
- void `CADC_HAL_ConfigController` (ADC_Type *base, const `cadc_controller_config_t` *configPtr)
Configures the common features in cyclic ADC module.
- void `CADC_HAL_ConfigConvA` (ADC_Type *base, const `cadc_converter_config_t` *configPtr)
Configures the features for the converter A.
- void `CADC_HAL_ConfigConvB` (ADC_Type *base, const `cadc_converter_config_t` *configPtr)
Configures the features for the conversion B.
- void `CADC_HAL_ConfigChn` (ADC_Type *base, const `cadc_chn_config_t` *configPtr)
Configures the feature for the sample channel.
- void `CADC_HAL_ConfigSeqSlot` (ADC_Type *base, uint32_t slotIdx, const `cadc_slot_config_t` *configPtr)
Configures the features for the sample sequence slot.
- static void `CADC_HAL_SetConvAStartCmd` (ADC_Type *base)
Executes the command that starts conversion of the converter A.
- static void `CADC_HAL_SetConvBStartCmd` (ADC_Type *base)
Executes the command that start conversion of the converter B.
- static void `CADC_HAL_SetConvAPowerDownCmd` (ADC_Type *base, bool enable)
Shuts down the conversion power manually for the converter A.
- static void `CADC_HAL_SetConvBPowerDownCmd` (ADC_Type *base, bool enable)
Shuts down the conversion power manually for the converter B.
- static bool `CADC_HAL_GetConvAInProgressFlag` (ADC_Type *base)

CADC HAL Driver

- Gets the flag whether the converter A is in process.*

 - static bool `CADC_HAL_GetConvBInProgressFlag` (ADC_Type *base)
- Gets the flag whether the converter B is in process.*

 - static bool `CADC_HAL_GetConvAEndOfScanIntFlag` (ADC_Type *base)
- Gets the flag whether the converter A has finished the conversion.*

 - static bool `CADC_HAL_GetConvBEndOfScanIntFlag` (ADC_Type *base)
- Gets the flag whether the converter B has finished the conversion.*

 - static void `CADC_HAL_ClearConvAEndOfScanIntFlag` (ADC_Type *base)
- Clears the flag that finishes the conversion of the converter A.*

 - static void `CADC_HAL_ClearConvBEndOfScanIntFlag` (ADC_Type *base)
- Clears the flag that finishes the conversion of the converter B.*

 - static bool `CADC_HAL_GetZeroCrossingIntFlag` (ADC_Type *base)
- Gets the flag whether a sample zero-crossing event has happened.*

 - static uint16_t `CADC_HAL_GetSlotZeroCrossingFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Gets the flag whether a sample zero-crossing event has happened.*

 - static void `CADC_HAL_ClearSlotZeroCrossingFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Clears the flags of a sample zero-crossing events.*

 - static bool `CADC_HAL_GetLowLimitIntFlag` (ADC_Type *base)
- Gets the flag whether any sample value is lower than the low limit value.*

 - static uint16_t `CADC_HAL_GetSlotLowLimitFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Gets the flags whether a sample value is lower than the low limit value.*

 - static void `CADC_HAL_ClearSlotLowLimitFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Clears the flags of the sample low limit event.*

 - static bool `CADC_HAL_GetHighLimitIntFlag` (ADC_Type *base)
- Gets the flag whether any sample value is higher than the high limit value.*

 - static uint16_t `CADC_HAL_GetSlotHighLimitFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Gets the flags whether a sample value is higher than the high limit value.*

 - static void `CADC_HAL_ClearSlotHighLimitFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Clears the flags of the sample high limit event.*

 - static uint16_t `CADC_HAL_GetSlotReadyFlag` (ADC_Type *base, uint16_t slotIdxMask)
- Gets the flags whether a sample value is ready.*

 - static bool `CADC_HAL_GetConvAPowerDownFlag` (ADC_Type *base)
- Gets the flag whether the converter A is powered down.*

 - static bool `CADC_HAL_GetConvBPowerDownFlag` (ADC_Type *base)
- Gets the flag whether the converter B is powered down.*

 - static uint16_t `CADC_HAL_GetSampleValue` (ADC_Type *base, uint16_t slotIdx)
- Gets the sample value.*

7.2.2 Data Structure Documentation

7.2.2.1 struct cadc_controller_config_t

This structure holds the configuration when initializing the CyclicADC module.

Data Fields

- bool `zeroCrossingIntEnable`
Global zero crossing interrupt enable.

- bool `lowLimitIntEnable`
Global low limit interrupt enable.
- bool `highLimitIntEnable`
Global high limit interrupt enable.
- `cadc_scan_mode_t` `scanMode`
ADC scan mode control.
- bool `parallelSimultModeEnable`
Parallel scans done simultaneously enable.
- `cadc_dma_trigger_src_t` `dmaSrc`
DMA trigger source.
- bool `autoStandbyEnable`
Auto standby mode enable.
- `uint16_t` `powerUpDelayCount`
Power up delay.
- bool `autoPowerDownEnable`
Auto power down mode enable.

7.2.2.2 struct `cadc_converter_config_t`

This structure holds the configuration for each converter in the CyclicADC module. Normally, there are two converters, ConvA and ConvB in the cyclic ADC module. However, each converter can be configured separately for some features.

Data Fields

- bool `dmaEnable`
DMA enable.
- bool `stopEnable`
Stop mode enable.
- bool `syncEnable`
Enable external sync input to trigger conversion.
- bool `endOfScanIntEnable`
End of scan interrupt enable.
- `uint16_t` `clkDivValue`
ADC clock divider from the bus clock.
- bool `useChnInputAsVrefH`
Use input channel as high reference voltage, such as AN2.
- bool `useChnInputAsVrefL`
Use input channel as low reference voltage, such as AN3.
- `cadc_conv_speed_mode_t` `speedMode`
ADC speed control mode.
- `uint16_t` `sampleWindowCount`
Sample window count.

7.2.2.3 struct `cadc_chn_config_t`

This structure holds the configuration for each input channel. In CyclicADC module, the input channels are handled by a differential sample. However, the user can still configure the function for each channel

CADC HAL Driver

when set to operate as a single end sample.

Data Fields

- `cadc_diff_chn_t diffChns`
Select the differential channel pair.
- `cadc_chn_sel_mode_t diffSelMode`
Select which channel is indicated in a pair.
- `cadc_gain_mode_t gainMode`
Gain mode for each channel.

7.2.2.4 struct `cadc_slot_config_t`

This structure holds the configuration for each slot in a conversion sequence.

Data Fields

- bool `slotDisable`
Keep the slot unavailable.
- bool `syncPointEnable`
Sample waits for an enabled SYNC input to occur.
- bool `syncIntEnable`
Scan interrupt enable.
- `cadc_diff_chn_t diffChns`
Select the differential pair.
- `cadc_chn_sel_mode_t diffSel`
Positive or negative channel in differential pair.
- `cadc_zero_crossing_mode_t zeroCrossingMode`
Select zero crossing detection mode.
- uint16_t `lowLimitValue`
Select low limit for hardware compare.
- uint16_t `highLimitValue`
Select high limit for hardware compare.
- uint16_t `offsetValue`
Select sign change limit for hardware compare.

7.2.3 Enumeration Type Documentation

7.2.3.1 enum `cadc_status_t`

Enumerator

- `kStatus_CADC_Success` Success.
- `kStatus_CADC_InvalidArgument` Invalid argument existed.
- `kStatus_CADC_Failed` Execution failed.

7.2.3.2 enum cadc_diff_chn_t

Note, "cadc_diff_chn_t" and "cadc_chn_sel_mode_t" can determine to select the single ADC sample channel.

Enumerator

kCAdcDiffChnANA0_1 ConvA's Chn 0 & 1.
kCAdcDiffChnANA2_3 ConvA's Chn 2 & 3.
kCAdcDiffChnANA4_5 ConvA's Chn 4 & 5.
kCAdcDiffChnANA6_7 ConvA's Chn 6 & 7.
kCAdcDiffChnANB0_1 ConvB's Chn 0 & 1.
kCAdcDiffChnANB2_3 ConvB's Chn 2 & 3.
kCAdcDiffChnANB4_5 ConvB's Chn 4 & 5.
kCAdcDiffChnANB6_7 ConvB's Chn 6 & 7.

7.2.3.3 enum cadc_chn_sel_mode_t

Note, "cadc_diff_chn_t" and "cadc_chn_sel_mode_t" can determine selecting the single ADC sample channel.

Enumerator

kCAdcChnSelN Selects a negative side channel.
kCAdcChnSelP Selects a positive side channel.
kCAdcChnSelBoth Selects both channels in differential modes.

7.2.3.4 enum cadc_scan_mode_t

See the ADC_CTRL1[SMODE] in the chip Reference Manual for detailed information about the ADC converter scan mode.

Enumerator

kCAdcScanOnceSequential Once (single) sequential.
kCAdcScanOnceParallel Once parallel.
kCAdcScanLoopSequential Loop sequential.
kCAdcScanLoopParallel Loop parallel.
kCAdcScanTriggeredSequential Triggered sequential.
kCAdcScanTriggeredParallel Triggered parallel (default).

7.2.3.5 enum cadc_zero_crossing_mode_t

Enumerator

kCAdcZeroCrossingDisable Zero crossing detection disabled.

CADC HAL Driver

- kCAdcZeroCrossingAtRisingEdge* Enable for positive to negative sign change.
- kCAdcZeroCrossingAtFallingEdge* Enable for negative to positive sign change.
- kCAdcZeroCrossingAtBothEdge* Enable for any sign change.

7.2.3.6 enum cadc_gain_mode_t

Enumerator

- kCAdcSGainBy1* x1 amplification.
- kCAdcSGainBy2* x2 amplification.
- kCAdcSGainBy4* x4 amplification.

7.2.3.7 enum cadc_conv_speed_mode_t

These items represent the clock speed at which the ADC converter can operate. Faster conversion speeds require greater current consumption.

Enumerator

- kCAdcConvClkLimitBy6_25MHz* Conversion clock frequency \leq 6.25 MHz; current consumption per converter = 6 mA.
- kCAdcConvClkLimitBy12_5MHz* Conversion clock frequency \leq 12.5 MHz; current consumption per converter = 10.8 mA.
- kCAdcConvClkLimitBy18_75MHz* Conversion clock frequency \leq 18.75 MHz; current consumption per converter = 18 mA.
- kCAdcConvClkLimitBy25MHz* Conversion clock frequency \leq 25 MHz; current consumption per converter = 25.2 mA.

7.2.3.8 enum cadc_dma_trigger_src_t

During sequential and simultaneous parallel scan modes, it selects between end of scan for ConvA's scan and RDY status as the DMA source. During non-simultaneous parallel scan mode it selects between end of scan for converters A and B, and the RDY status as the DMA source.

Enumerator

- kCAdcDmaTriggeredByEndOfScan* DMA trigger source is end of scan interrupt.
- kCAdcDmaTriggeredByConvReady* DMA trigger source is RDY status.

7.2.4 Function Documentation

7.2.4.1 void CADC_HAL_Init (ADC_Type * base)

The initial states of ADC registers are set as specified in the chip Reference Manual.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

7.2.4.2 void CADC_HAL_ConfigController (ADC_Type * *base*, const *cadc_controller_config_t* * *configPtr*)

This function configures the common features in cyclic ADC module. For detailed items, see the "cadc_controller_config_t".

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

7.2.4.3 void CADC_HAL_ConfigConvA (ADC_Type * *base*, const *cadc_converter_config_t* * *configPtr*)

This function configures the features for the converter A. For detailed items, see the "cadc_converter_config_t".

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

7.2.4.4 void CADC_HAL_ConfigConvB (ADC_Type * *base*, const *cadc_converter_config_t* * *configPtr*)

This function configures the features for the conversion B. For detailed items, see the "cadc_converter_config_t".

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

CADC HAL Driver

7.2.4.5 void CADC_HAL_ConfigChn (ADC_Type * *base*, const cadc_chn_config_t * *configPtr*)

This function configures the features for the sample channel. For detailed items, see the "cadc_chn_config_t".

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. |

7.2.4.6 void CADC_HAL_ConfigSeqSlot (ADC_Type * *base*, uint32_t *slotIdx*, const cadc_slot_config_t * *configPtr*)

This function configures the features for the sample sequence slot. For detailed items, see the "cadc_slot_config_t".

Parameters

| | |
|------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdx</i> | Sample slot index. |
| <i>configPtr</i> | Pointer to configuration structure. |

7.2.4.7 static void CADC_HAL_SetConvAStartCmd (ADC_Type * *base*) [inline], [static]

This function executes the command that start the conversion of the converter A when using the software trigger.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

7.2.4.8 static void CADC_HAL_SetConvBStartCmd (ADC_Type * *base*) [inline], [static]

This function executes the command that start the conversion of the converter B when using the software trigger.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

7.2.4.9 **static void CADC_HAL_SetConvAPowerDownCmd (ADC_Type * *base*, bool *enable*) [inline], [static]**

This function shuts down the conversion power manually for the conversion A. The conversion stops immediately after calling this function.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the module. |
| <i>enable</i> | Switcher to enable the feature or not. |

7.2.4.10 **static void CADC_HAL_SetConvBPowerDownCmd (ADC_Type * *base*, bool *enable*) [inline], [static]**

This function shuts down the conversion power manually for the conversion B. The conversion stops immediately after calling this function.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for the module. |
| <i>enable</i> | Switcher to enable the feature or not. |

7.2.4.11 **static bool CADC_HAL_GetConvAInProgressFlag (ADC_Type * *base*) [inline], [static]**

This function gets the flag whether the converter A is in process.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

CADC HAL Driver

7.2.4.12 `static bool CADC_HAL_GetConvBInProgressFlag (ADC_Type * base)`
`[inline], [static]`

This function gets the flag whether the converter B is in process.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

**7.2.4.13 static bool CADC_HAL_GetConvAEndOfScanIntFlag (ADC_Type * *base*)
[inline], [static]**

This function gets the flag whether the converter A has finished the conversion.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

**7.2.4.14 static bool CADC_HAL_GetConvBEndOfScanIntFlag (ADC_Type * *base*)
[inline], [static]**

This function gets the flag whether the converter B has finished the conversion.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

**7.2.4.15 static void CADC_HAL_ClearConvAEndOfScanIntFlag (ADC_Type * *base*)
[inline], [static]**

This function clears the flag that finishes the conversion of the converter A.

CADC HAL Driver

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

**7.2.4.16 static void CADC_HAL_ClearConvBEndOfScanIntFlag (ADC_Type * *base*)
[inline], [static]**

This function clears the flag that finishes the conversion of the converter B.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

**7.2.4.17 static bool CADC_HAL_GetZeroCrossingIntFlag (ADC_Type * *base*)
[inline], [static]**

This function gets the flag whether any sample zero-crossing event has happened.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

**7.2.4.18 static uint16_t CADC_HAL_GetSlotZeroCrossingFlag (ADC_Type * *base*,
uint16_t *slotIdxMask*) [inline], [static]**

This function gets the flags whether a sample zero-crossing event has happened.

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

Returns

flags whether the event are happened for indicated slots.

7.2.4.19 `static void CADC_HAL_ClearSlotZeroCrossingFlag (ADC_Type * base, uint16_t slotIdxMask) [inline], [static]`

This function clears the flags of the sample zero-crossing events.

CADC HAL Driver

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

7.2.4.20 **static bool CADC_HAL_GetLowLimitIntFlag (ADC_Type * *base*) [inline], [static]**

This function gets the flag whether any sample value is lower than the low limit value.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

7.2.4.21 **static uint16_t CADC_HAL_GetSlotLowLimitFlag (ADC_Type * *base*, uint16_t *slotIdxMask*) [inline], [static]**

This function gets the flags whether a samples value is lower than the low limit value.

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

Returns

flags whether the event are happened for indicated slots.

7.2.4.22 **static void CADC_HAL_ClearSlotLowLimitFlag (ADC_Type * *base*, uint16_t *slotIdxMask*) [inline], [static]**

This function clears the flags of the sample low limit event.

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

7.2.4.23 static bool CADC_HAL_GetHighLimitIntFlag (ADC_Type * *base*) [inline], [static]

This function gets the flag whether any sample value is higher than the high limit value.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

7.2.4.24 static uint16_t CADC_HAL_GetSlotHighLimitFlag (ADC_Type * *base*, uint16_t *slotIdxMask*) [inline], [static]

This function gets the flags whether a sample value is higher than the high limit value.

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

Returns

flags whether the event are happened for indicated slots.

7.2.4.25 static void CADC_HAL_ClearSlotHighLimitFlag (ADC_Type * *base*, uint16_t *slotIdxMask*) [inline], [static]

This function clears the flags of the sample high limit event.

CADC HAL Driver

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

7.2.4.26 `static uint16_t CADC_HAL_GetSlotReadyFlag (ADC_Type * base, uint16_t slotIdxMask) [inline], [static]`

This function gets the flags whether a sample value is ready.

Parameters

| | |
|--------------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdxMask</i> | Mask for indicated slots. |

Returns

flags whether the event are happened for indicated slots.

7.2.4.27 `static bool CADC_HAL_GetConvAPowerDownFlag (ADC_Type * base) [inline], [static]`

This function gets the flag whether the converter A is powered down.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

7.2.4.28 `static bool CADC_HAL_GetConvBPowerDownFlag (ADC_Type * base) [inline], [static]`

This function gets the flag whether the converter B is powered down.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The event is asserted or not.

7.2.4.29 static uint16_t CADC_HAL_GetSampleValue (ADC_Type * *base*, uint16_t *slotIdx*) [inline], [static]

This function gets the sample value. Note that the 3 LSBs are not available. When the differential conversion is executed, the MSB is the sign bit.

Parameters

| | |
|----------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
| <i>slotIdx</i> | Index of slot in conversion sequence. |

Returns

sample value with sign bit in MSB.

CADC Peripheral Driver

7.3 CADC Peripheral Driver

7.3.1 Overview

This section describes the programming interface of the CADC Peripheral driver. The CADC peripheral driver configures the Cyclic ADC (12-bit Cyclic Analog-to-Digital Converter). It handles initialization, configuration and controlling the conversion of this module.

7.3.2 CADC Driver model building

CADC driver has four objects:

- ADC Converter - CADC module has two ADC converters, ConvA and ConvB, which are the two independent sample and hold (S/H) circuits. They can work simultaneously or individually for each conversion. The driver provides APIs to configure each converter separately.
 - Conversion sequence - Conversion sequence is the basic execution unit for the CADC module. Starting a single conversion either launches a sequence of conversions or a scan. Each slot in the sequence can be configured as an input sample channel from the channel multiplexer. The conversion result is stored in the related result register. Additional features, such as zero-crossing detection and low/high limit detection can be attached to the conversion for each slot. The driver provides APIs to configure each slot in the sequence.
 - Input multiplexer - 16 input single-end inputs for the CADC module are grouped for each converter, ANA0 - ANA7 belong to ConvA, ANB0 - ANB7 belong to ConvB. As a result, only the unique host converter can convert the indicated input channel. Inputs are grouped for the differential sample so that ANA[0:1], ANA[2:3], ANA[4:5], ANA[6:7], ANB[0:1], ANB[2:3], ANB[4:5], ANB[6:7]. In this case, a channel with an even number is positive and the channel with an odd number is negative. The driver provides APIs to configure each input channel.
 - Global setting - Global setting covers all shared configurations. The driver provides APIs to configure the global setting.

7.3.3 CADC Work mode

The ADC operates either in a sequential scan mode or a parallel scan mode. In the sequential scan mode, the scan sequence is determined by defining the 16 sample slots that are processed in order, SAMPLE[0:15]. In the parallel scan mode, ConvA processes SAMPLE[0:7] in order and ConvB processes SAMPLE[8:15] in order.

- In the sequential scan mode, a scan takes up to 16 single-ended or differential samples, one at a time.
- In the parallel scan mode, 8 of the 16 samples are allocated to ConvA and the other 8 are allocated to ConvB. Two converters operate in parallel such that each can take at most 8 samples. ConvA can sample only analog inputs ANA[0:7] and ConvB can sample only analog inputs ANB[0:7].

The parallel scan mode is simultaneous or non-simultaneous:

- In the simultaneous scan mode, parallel scans in the two converters occur simultaneously and result in simultaneous pairs of conversions, one by ConvA and one by ConvB. The two converters share the same start, stop, sync, end-of-scan interrupt enable control, and interrupts. Scanning in both converters terminates when either converter encounters a disabled sample.
- In the non-simultaneous scan mode, parallel scans in the two converters occur independently. Each converter has its own start, stop, sync, end-of-scan interrupt enable controls, and interrupts. Scanning in either converter terminates only when that converter encounters a disabled sample.

The ADC can be configured to perform a single scan and halt, perform a scan whenever triggered, or perform the scan sequence repeatedly until manually stopped. The single scan (once mode) differs from the triggered mode only in that SYNC input signals must be re-armed after each use and subsequent SYNC inputs are ignored until the SYNC input is re-armed. Arming can occur any time after the SYNC pulse, including while the scan is still in process.

7.3.4 CADC Interrupt

There are three categories of ADC interrupts:

- Threshold interrupts, which are caused by three different events:
 - Zero crossing — occurs if the current result value has a sign change from the previous result.
 - Low limit exceeded error — occurs when the current result value is less than the setting value for the low limit. The raw result value is compared to the setting value for the low limit before the offset register value is subtracted.
 - High limit exceeded error — is asserted if the current result value is greater than the setting value for the high limit. The raw result value is compared to the setting value for the high limit.
- Conversion complete interrupts, which are generated upon completion of any scan and convert sequence when enabling the interrupt.
- Scan interrupts are generated when a sample is converted. This allows processing of intermediate conversion data during a scan.

7.3.5 CADC Call diagram

When using the CADC module, all four objects should be configured according to the application requirements. This example illustrates how to use the CADC driver.

```
// Four kinds of structures to configure Cyclic ADC with conversion sequence. //
cadc_controller_config_t g_AdcUserConfigStruct;
cadc_chn_config_t g_AdcChnConfigStruct;
cadc_converter_config_t g_AdcConvConfigStruct;
cadc_slot_config_t g_AdcSlotConfigStruct;

static uint32_t CADC_DRV_TEST_PollingMode(uint32_t instance);

int main(void)
{
    uint32_t idx;
    uint32_t errCounter = 0U;
    uint32_t totalErrCounter = 0U;
```

CADC Peripheral Driver

```

hardware_init();
dbg_uart_init();

PRINTF("\r\nCADC PD driver Test: Start...\r\n");

for (idx = 0U; idx < 1; idx++)
{
    printf("CADC instance: %d.\r\n", idx);
    errCounter = 0U;

    errCounter += CADC_DRV_TEST_PollingMode(idx);

    PRINTF("CADC %d PD driver Test error counter: %d\r\n", idx, errCounter);
    totalErrCounter += errCounter;
}

PRINTF("CADC PD driver Test: End\r\n");

// Print log for auto run detection. //
PRINTF("CADC PD driver Test ");
if (0U == totalErrCounter)
{
    PRINTF("Succeed\r\n");
}
else
{
    PRINTF("Error\r\n");
}

while ('c' != getchar()) {}
return 0;
}

Enumerations

- enum `cadc_conv_id_t` {
`kCAdcConvA` = 0U,
`kCAdcConvB` = 1U }
Defines the type of enumerating ADC converter ID.
- enum `cadc_flag_t` {
`kCAdcConvInProgress` = 0U,
`kCAdcConvEndOfScanInt` = 1U,
`kCAdcConvPowerDown` = 2U,
`kCAdcZeroCrossingInt` = 3U,
`kCAdcLowLimitInt` = 4U,
`kCAdcHighLimitInt` = 5U,
`kCAdcSlotReady` = 6U,
`kCAdcSlotLowLimitEvent` = 7U,
`kCAdcSlotHighLimitEvent` = 8U,
`kCAdcSlotCrossingEvent` = 9U }
Defines types for an enumerating event.

Variables

- ADC_Type * `g_cadcBaseAddr` []
Table of base addresses for ADC instances.
- IRQn_Type `g_cadcErrIrqId` [ADC_INSTANCE_COUNT]
Table to save ADC IRQ enumeration numbers defined in the CMSIS header file.

CADC Driver

- `cadc_status_t CADC_DRV_StructInitUserConfigDefault` (`cadc_controller_config_t *userConfigPtr`)
Populates the user configuration structure for the CyclicADC common settings.
- `cadc_status_t CADC_DRV_Init` (`uint32_t instance`, `const cadc_controller_config_t *userConfigPtr`)
Initializes the CyclicADC module for a global configuration.
- `cadc_status_t CADC_DRV_Deinit` (`uint32_t instance`)
De-initializes the CyclicADC module.
- `cadc_status_t CADC_DRV_StructInitConvConfigDefault` (`cadc_converter_config_t *configPtr`)

- Populates the user configuration structure for each converter.*

 - `cadc_status_t CADC_DRV_ConfigConverter` (`uint32_t` instance, `cadc_conv_id_t` convId, const `cadc_converter_config_t *configPtr`)

Configures each converter in the CyclicADC module.

 - `cadc_status_t CADC_DRV_ConfigSampleChn` (`uint32_t` instance, const `cadc_chn_config_t *configPtr`)

Configures the input channel for ADC conversion.

 - `cadc_status_t CADC_DRV_ConfigSeqSlot` (`uint32_t` instance, `uint32_t` slotIdx, const `cadc_slot_config_t *configPtr`)

Configures each slot for the ADC conversion sequence.

 - void `CADC_DRV_SoftTriggerConv` (`uint32_t` instance, `cadc_conv_id_t` convId)

Triggers the ADC conversion sequence by software.

 - `uint16_t CADC_DRV_GetSeqSlotConvValue` (`uint32_t` instance, `uint32_t` slotIdx)

Reads the conversion value and returns an absolute value.

 - bool `CADC_DRV_GetFlag` (`uint32_t` instance, `cadc_flag_t` flag)

Gets the global event flag.

 - void `CADC_DRV_ClearFlag` (`uint32_t` instance, `cadc_flag_t` flag)

Clears the global event flag.

 - bool `CADC_DRV_GetConvFlag` (`uint32_t` instance, `cadc_conv_id_t` convId, `cadc_flag_t` flag)

Gets the flag for each converter event.

 - void `CADC_DRV_ClearConvFlag` (`uint32_t` instance, `cadc_conv_id_t` convId, `cadc_flag_t` flag)

Clears the flag for each converter event.

 - `uint16_t CADC_DRV_GetSlotFlag` (`uint32_t` instance, `uint16_t` slotIdxMask, `cadc_flag_t` flag)

Gets the flag for each slot event.

 - void `CADC_DRV_ClearSlotFlag` (`uint32_t` instance, `uint16_t` slotIdxMask, `cadc_flag_t` flag)

Clears the flag for each slot event.

7.3.6 Enumeration Type Documentation

7.3.6.1 enum cadc_conv_id_t

Enumerator

- `kCAdcConvA` ID for ADC converter A.
- `kCAdcConvB` ID for ADC converter B.

7.3.6.2 enum cadc_flag_t

Enumerator

- `kCAdcConvInProgress` Conversion in progress for each converter.
- `kCAdcConvEndOfScanInt` End of scan interrupt.
- `kCAdcConvPowerDown` The converter is powered Down.
- `kCAdcZeroCrossingInt` Zero crossing interrupt.
- `kCAdcLowLimitInt` Low limit interrupt.
- `kCAdcHighLimitInt` High limit interrupt.
- `kCAdcSlotReady` Sample is ready to be read.

CADC Peripheral Driver

- kCAdcSlotLowLimitEvent* Low limit event for each slot.
- kCAdcSlotHighLimitEvent* High limit event for each slot.
- kCAdcSlotCrossingEvent* Zero crossing event for each slot.

7.3.7 Function Documentation

7.3.7.1 `cadc_status_t CADC_DRV_StructInitUserConfigDefault (cadc_controller_config_t * userConfigPtr)`

This function populates the `cadc_user_config_t` structure with default settings, which are used in polling mode for ADC conversion. These settings are:

```
.zeroCrossingIntEnable = false; .lowLimitIntEnable = false; .highLimitIntEnable = false; .scanMode = kCAdcScanOnceSequential; .parallelSimultModeEnable = false; .dmaSrc = kCAdcDmaTriggeredByEndOfScan; .autoStandbyEnable = false; .powerUpDelayCount = 0x2AU; .autoPowerDownEnable = false;
```

Parameters

| | |
|----------------------|---|
| <i>userConfigPtr</i> | Pointer to structure of "cadc_controller_config_t". |
|----------------------|---|

Returns

Execution status.

7.3.7.2 `cadc_status_t CADC_DRV_Init (uint32_t instance, const cadc_controller_config_t * userConfigPtr)`

This function configures the CyclicADC module for the global configuration which is shared by all converters.

Parameters

| | |
|----------------------|---|
| <i>instance</i> | Instance ID number. |
| <i>userConfigPtr</i> | Pointer to structure of "cadc_controller_config_t". |

Returns

Execution status.

7.3.7.3 `cadc_status_t CADC_DRV_Deinit (uint32_t instance)`

This function shuts down the CyclicADC module and disables related IRQs.

Parameters

| | |
|-----------------|---------------------|
| <i>instance</i> | Instance ID number. |
|-----------------|---------------------|

Returns

Execution status.

7.3.7.4 **cadc_status_t CADC_DRV_StructInitConvConfigDefault (cadc_converter_config_t * configPtr)**

This function populates the `cadc_conv_config_t` structure with default settings, which are used in polling mode for ADC conversion. These settings are:

```
.dmaEnable = false; .stopEnable = false; .syncEnable = false; .endOfScanIntEnable = false; .clkDivValue = 0x3FU; .useChnInputAsVrefH = false; .useChnInputAsVrefL = false; .speedMode = kCAdcConvClkLimitBy25MHz; .sampleWindowCount = 0U;
```

Parameters

| | |
|------------------|--|
| <i>configPtr</i> | Pointer to structure of "cadc_converter_config_t". |
|------------------|--|

Returns

Execution status.

7.3.7.5 **cadc_status_t CADC_DRV_ConfigConverter (uint32_t instance, cadc_conv_id_t convId, const cadc_converter_config_t * configPtr)**

This function configures each converter in the CyclicADC module. However, when the multiple converters are operating simultaneously, the converter settings are interrelated. For more information, see the appropriate device reference manual.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>convId</i> | Converter ID. See "cadc_conv_id_t". |

CADC Peripheral Driver

| | |
|------------------|--|
| <i>configPtr</i> | Pointer to configure structure. See "cadc_converter_config_t". |
|------------------|--|

Returns

Execution status.

7.3.7.6 **cadc_status_t** CADC_DRV_ConfigSampleChn (**uint32_t** *instance*, **const** **cadc_chn_config_t** * *configPtr*)

This function configures the input channel for ADC conversion. The CyclicADC module input channels are organized in pairs. The configuration can be set for each channel in the pair.

Parameters

| | |
|------------------|--|
| <i>instance</i> | Instance ID number. |
| <i>configPtr</i> | Pointer to configure structure. See "cadc_chn_config_t". |

Returns

Execution status.

7.3.7.7 **cadc_status_t** CADC_DRV_ConfigSeqSlot (**uint32_t** *instance*, **uint32_t** *slotIdx*, **const** **cadc_slot_config_t** * *configPtr*)

This function configures each slot in the ADC conversion sequence. ADC conversion sequence is the basic execution unit in the CyclicADC module. However, the sequence should be configured slot-by-slot. The end of the sequence is a slot that is configured as disabled.

Parameters

| | |
|------------------|---|
| <i>instance</i> | Instance ID number. |
| <i>slotIdx</i> | Indicated slot number, available in range of 0 - 15. |
| <i>configPtr</i> | Pointer to configure structure. See "cadc_slot_config_t". |

Returns

Execution status.

7.3.7.8 **void** CADC_DRV_SoftTriggerConv (**uint32_t** *instance*, **cadc_conv_id_t** *convId*)

This function triggers the ADC conversion by executing a software command. It starts the conversion if no other SYNC input (hardware trigger) is needed.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | Instance ID number. |
| <i>convId</i> | Indicated converter. See "cadc_conv_id_t". |

7.3.7.9 uint16_t CADC_DRV_GetSeqSlotConvValue (uint32_t instance, uint32_t slotIdx)

This function reads the conversion value from each slot in a conversion sequence. The return value is the absolute value without being signed.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | Instance ID number. |
| <i>slotIdx</i> | Indicated slot number, available in range of 0 - 15. |

Returns

The conversion value.

7.3.7.10 bool CADC_DRV_GetFlag (uint32_t instance, cadc_flag_t flag)

This function gets the global flag of the CyclicADC module.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

Returns

Assertion of indicated event.

7.3.7.11 void CADC_DRV_ClearFlag (uint32_t instance, cadc_flag_t flag)

This function clears the global event flag of the CyclicADC module.

CADC Peripheral Driver

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

7.3.7.12 **bool CADC_DRV_GetConvFlag (uint32_t instance, cadc_conv_id_t convId, cadc_flag_t flag)**

This function gets the flag for each converter event.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>convId</i> | Indicated converter. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

Returns

Assertion of indicated event.

7.3.7.13 **void CADC_DRV_ClearConvFlag (uint32_t instance, cadc_conv_id_t convId, cadc_flag_t flag)**

This function clears the flag for each converter event.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>convId</i> | Indicated converter. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

7.3.7.14 **uint16_t CADC_DRV_GetSlotFlag (uint32_t instance, uint16_t slotIdxMask, cadc_flag_t flag)**

This function gets the flag for each slot event in the conversion in sequence.

Parameters

| | |
|--------------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>slotIdxMask</i> | Indicated slot number's mask. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

Returns

Assertion of indicated event.

7.3.7.15 void CADC_DRV_ClearSlotFlag (uint32_t instance, uint16_t slotIdxMask, cadc_flag_t flag)

This function clears the flag for each slot event in the conversion in sequence.

Parameters

| | |
|--------------------|-------------------------------------|
| <i>instance</i> | Instance ID number. |
| <i>slotIdxMask</i> | Indicated slot number's mask. |
| <i>flag</i> | Indicated event. See "cadc_flag_t". |

Chapter 8 Comparator (CMP)

8.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Comparator (CMP) block of Kinetis devices.

Modules

- [CMP HAL Driver](#)
- [CMP Peripheral Driver](#)

CMP HAL Driver

8.2 CMP HAL Driver

8.2.1 Overview

This section describes the programming interface of the CMP HAL driver.

Data Structures

- struct [cmp_comparator_config_t](#)
Defines a structure for configuring the comparator in the CMP module. [More...](#)
- struct [cmp_sample_filter_config_t](#)
Defines a structure to configure the window/filter in CMP module. [More...](#)
- struct [cmp_dac_config_t](#)
Defines a structure to configure the internal DAC in the CMP module. [More...](#)

Enumerations

- enum [cmp_status_t](#) {
 [kStatus_CMP_Success](#) = 0U,
 [kStatus_CMP_InvalidArgument](#) = 1U,
 [kStatus_CMP_Failed](#) = 2U }
CMP status return codes.
- enum [cmp_hystersis_mode_t](#) {
 [kCmpHystersisOfLevel0](#) = 0U,
 [kCmpHystersisOfLevel1](#) = 1U,
 [kCmpHystersisOfLevel2](#) = 2U,
 [kCmpHystersisOfLevel3](#) = 3U }
Defines the selections of the hard block hysteresis control level.
- enum [cmp_filter_counter_mode_t](#) {
 [kCmpFilterCountSampleOf0](#) = 0U,
 [kCmpFilterCountSampleOf1](#) = 1U,
 [kCmpFilterCountSampleOf2](#) = 2U,
 [kCmpFilterCountSampleOf3](#) = 3U,
 [kCmpFilterCountSampleOf4](#) = 4U,
 [kCmpFilterCountSampleOf5](#) = 5U,
 [kCmpFilterCountSampleOf6](#) = 6U,
 [kCmpFilterCountSampleOf7](#) = 7U }
Defines the selections of the filter sample counter.
- enum [cmp_dac_ref_volt_src_mode_t](#) {
 [kCmpDacRefVoltSrcOf1](#) = 0U,
 [kCmpDacRefVoltSrcOf2](#) = 1U }
Defines the selections of reference voltage source for the internal DAC.
- enum [cmp_chn_mux_mode_t](#) {

```

kCmpInputChn0 = 0U,
kCmpInputChn1 = 1U,
kCmpInputChn2 = 2U,
kCmpInputChn3 = 3U,
kCmpInputChn4 = 4U,
kCmpInputChn5 = 5U,
kCmpInputChn6 = 6U,
kCmpInputChn7 = 7U,
kCmpInputChnDac = kCmpInputChn7 }

```

Define the selection of the CMP channel mux.

- enum `cmp_sample_filter_mode_t` {

```

kCmpContinuousMode = 0U,
kCmpSampleWithNoFilteredMode = 1U,
kCmpSampleWithFilteredMode = 2U,
kCmpWindowedMode = 3U,
kCmpWindowedFilteredMode = 4U }

```

Definition selections of the sample and filter modes in the CMP module.

Functions

- void `CMP_HAL_Init` (CMP_Type *base)

Resets the CMP registers to a known state.
- void `CMP_HAL_ConfigComparator` (CMP_Type *base, const `cmp_comparator_config_t` *configPtr)

Configures the CMP comparator function.
- void `CMP_HAL_ConfigDacChn` (CMP_Type *base, const `cmp_dac_config_t` *configPtr)

Configures the CMP DAC function.
- void `CMP_HAL_ConfigSampleFilter` (CMP_Type *base, const `cmp_sample_filter_config_t` *configPtr)

Configures the CMP sample or the filter function.
- static void `CMP_HAL_Enable` (CMP_Type *base)

Enables the comparator in the CMP module.
- static void `CMP_HAL_Disable` (CMP_Type *base)

Disables the comparator in the CMP module.
- static bool `CMP_HAL_GetOutputLogic` (CMP_Type *base)

Gets the comparator logic output in the CMP module.
- static bool `CMP_HAL_GetOutputFallingFlag` (CMP_Type *base)

Gets the logic output falling edge event in the CMP module.
- static void `CMP_HAL_ClearOutputFallingFlag` (CMP_Type *base)

Clears the logic output falling edge event in the CMP module.
- static bool `CMP_HAL_GetOutputRisingFlag` (CMP_Type *base)

Gets the logic output rising edge event in the CMP module.
- static void `CMP_HAL_ClearOutputRisingFlag` (CMP_Type *base)

Clears the logic output rising edge event in the CMP module.

CMP HAL Driver

8.2.2 Data Structure Documentation

8.2.2.1 struct cmp_comparator_config_t

This structure holds the configuration for the comparator inside the CMP module. With the configuration, the CMP can be set as a basic comparator without additional features.

Data Fields

- [cmp_hystersis_mode_t hystersisMode](#)
Set the hysteresis level.
- bool [pinoutEnable](#)
Enable outputting the CMPO to pin.
- bool [pinoutUnfilteredEnable](#)
Enable outputting unfiltered result to CMPO.
- bool [invertEnable](#)
Enable inverting the comparator's result.
- bool [highSpeedEnable](#)
Enable working in speed mode.
- bool [risingIntEnable](#)
Enable using CMPO rising interrupt.
- bool [fallingIntEnable](#)
Enable using CMPO falling interrupt.
- [cmp_chn_mux_mode_t plusChnMux](#)
Set the Plus side input to comparator.
- [cmp_chn_mux_mode_t minusChnMux](#)
Set the Minus side input to comparator.

8.2.2.2 struct cmp_sample_filter_config_t

This structure holds the configuration for the window/filter inside the CMP module. With the configuration, the CMP module can operate in advanced mode.

Data Fields

- [cmp_sample_filter_mode_t workMode](#)
Sample/Filter's work mode.
- bool [useExtSampleOrWindow](#)
Switcher to use external WINDOW/SAMPLE signal.
- uint8_t [filterClkDiv](#)
Filter's prescaler which divides from the bus clock.
- [cmp_filter_counter_mode_t filterCount](#)
Sample count for filter.

8.2.2.2.0.6 Field Documentation

8.2.2.2.0.6.1 `cmp_filter_counter_mode_t` `cmp_sample_filter_config_t::filterCount`

See "`cmp_filter_counter_mode_t`".

8.2.2.3 `struct cmp_dac_config_t`

This structure holds the configuration for the DAC inside the CMP module. With the configuration, the internal DAC provides a reference voltage level and is chosen as the CMP input.

Data Fields

- bool `dacEnable`
Enable the internal 6-bit DAC.
- `cmp_dac_ref_volt_src_mode_t` `refVoltSrcMode`
Select the reference voltage source for internal DAC.
- `uint8_t` `dacValue`
Set the value for internal DAC.

8.2.3 Enumeration Type Documentation

8.2.3.1 `enum cmp_status_t`

Enumerator

- `kStatus_CMP_Success` Success.
- `kStatus_CMP_InvalidArgument` Invalid argument existed.
- `kStatus_CMP_Failed` Execution failed.

8.2.3.2 `enum cmp_hystersis_mode_t`

The hysteresis control level indicates the smallest window between the two inputs when asserting the change of output. See the chip Data Sheet for detailed electrical characteristics. Generally, the lower level represents the smaller window.

Enumerator

- `kCmpHystersisOfLevel0` Level 0.
- `kCmpHystersisOfLevel1` Level 1.
- `kCmpHystersisOfLevel2` Level 2.
- `kCmpHystersisOfLevel3` Level 3.

CMP HAL Driver

8.2.3.3 enum cmp_filter_counter_mode_t

The selection item represents the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state.

Enumerator

| | |
|---------------------------------|----------------------------------|
| <i>kCmpFilterCountSampleOf0</i> | Disable the filter. |
| <i>kCmpFilterCountSampleOf1</i> | One sample must agree. |
| <i>kCmpFilterCountSampleOf2</i> | 2 consecutive samples must agree |
| <i>kCmpFilterCountSampleOf3</i> | 3 consecutive samples must agree |
| <i>kCmpFilterCountSampleOf4</i> | 4 consecutive samples must agree |
| <i>kCmpFilterCountSampleOf5</i> | 5 consecutive samples must agree |
| <i>kCmpFilterCountSampleOf6</i> | 6 consecutive samples must agree |
| <i>kCmpFilterCountSampleOf7</i> | 7 consecutive samples must agree |

8.2.3.4 enum cmp_dac_ref_volt_src_mode_t

Enumerator

| | |
|-----------------------------|------------------|
| <i>kCmpDacRefVoltSrcOf1</i> | Vin1 - Vref_out. |
| <i>kCmpDacRefVoltSrcOf2</i> | Vin2 - Vdd. |

8.2.3.5 enum cmp_chn_mux_mode_t

Enumerator

| | |
|------------------------|-----------------------------|
| <i>kCmpInputChn0</i> | Comparator input channel 0. |
| <i>kCmpInputChn1</i> | Comparator input channel 1. |
| <i>kCmpInputChn2</i> | Comparator input channel 2. |
| <i>kCmpInputChn3</i> | Comparator input channel 3. |
| <i>kCmpInputChn4</i> | Comparator input channel 4. |
| <i>kCmpInputChn5</i> | Comparator input channel 5. |
| <i>kCmpInputChn6</i> | Comparator input channel 6. |
| <i>kCmpInputChn7</i> | Comparator input channel 7. |
| <i>kCmpInputChnDac</i> | Comparator input channel 7. |

8.2.3.6 enum cmp_sample_filter_mode_t

Comparator sample/filter is available in several modes. Use the enumeration to identify the comparator's status:

kCmpContinuousMode - Continuous Mode: Both window control and filter blocks are completely bypassed. The comparator output is updated continuously. *kCmpSampleWithNoFilteredMode* - Sample,

Non-Filtered Mode: Window control is completely bypassed. The comparator output is sampled whenever a rising-edge is detected on the filter block clock input. The filter clock prescaler can be configured as a divider from the bus clock. *kCmpSampleWithFilteredMode* - Sample, Filtered Mode: Similar to "-Sample, Non-Filtered Mode", but the filter is active in this mode. The filter counter value also becomes configurable. *kCmpWindowedMode* - Windowed Mode: In Windowed Mode, only output of analog comparator is passed when the WINDOW signal is high. The last latched value is held when the WINDOW signal is low. *kCmpWindowedFilteredMode* - Window/Filtered Mode: This is a complex mode because it uses both window and filtering features. It also has the highest latency of all modes. This can be approximated to up to 1 bus clock synchronization in the window function

- ((filter counter * filter prescaler) + 1) bus clock for the filter function.

Enumerator

- kCmpContinuousMode* Continuous Mode.
- kCmpSampleWithNoFilteredMode* Sample, Non-Filtered Mode.
- kCmpSampleWithFilteredMode* Sample, Filtered Mode.
- kCmpWindowedMode* Window Mode.
- kCmpWindowedFilteredMode* Window/Filtered Mode.

8.2.4 Function Documentation

8.2.4.1 void CMP_HAL_Init (CMP_Type * base)

This function resets the CMP registers to a known state. This state is defined in the chip Reference Manual, which is power on reset value.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

8.2.4.2 void CMP_HAL_ConfigComparator (CMP_Type * base, const cmp_comparator_config_t * configPtr)

This function configures the CMP comparator function.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

CMP HAL Driver

| | |
|------------------|---|
| <i>configPtr</i> | Pointer to configuration structure. See to "cmp_comparator_config_t". |
|------------------|---|

8.2.4.3 void CMP_HAL_ConfigDacChn (CMP_Type * *base*, const cmp_dac_config_t * *configPtr*)

This function configures the CMP DAC function.

Parameters

| | |
|------------------|--|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. See to "cmp_dac_config_t". |

8.2.4.4 void CMP_HAL_ConfigSampleFilter (CMP_Type * *base*, const cmp_sample_filter_config_t * *configPtr*)

This function configures the CMP sample or filter function.

Parameters

| | |
|------------------|--|
| <i>base</i> | Register base address for the module. |
| <i>configPtr</i> | Pointer to configuration structure. See to "cmp_sample_filter_config_t". |

8.2.4.5 static void CMP_HAL_Enable (CMP_Type * *base*) [inline], [static]

This function enables the comparator in the CMP module. The analog comparator is the core component in the CMP module. Only when it is enabled, all other functions for advanced features are meaningful.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

8.2.4.6 static void CMP_HAL_Disable (CMP_Type * *base*) [inline], [static]

This function disables the comparator in the CMP module. The analog comparator is the core component in the CMP module. When it is disabled, it remains in the off state and consumes no power.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

8.2.4.7 static bool CMP_HAL_GetOutputLogic (CMP_Type * *base*) [inline], [static]

This function gets the comparator logic output in the CMP module. It returns the current value of the analog comparator output. The value is reset to 0 and read as de-asserted value when the CMP module is disabled. When setting to invert mode, the comparator logic output is inverted as well.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The logic output is assert or not.

8.2.4.8 static bool CMP_HAL_GetOutputFallingFlag (CMP_Type * *base*) [inline], [static]

This function gets the logic output falling edge event in the CMP module. It detects a falling-edge on COUT and returns the asserted state when the falling-edge on COUT has occurred.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The falling-edge on COUT has occurred or not.

8.2.4.9 static void CMP_HAL_ClearOutputFallingFlag (CMP_Type * *base*) [inline], [static]

This function clears the logic output falling edge event in the CMP module.

CMP HAL Driver

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

8.2.4.10 **static bool CMP_HAL_GetOutputRisingFlag (CMP_Type * *base*) [inline], [static]**

This function gets the logic output rising edge event in the CMP module. It detects a rising-edge on COUT and returns the asserted state when the rising-edge on COUT has occurred.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

Returns

The rising-edge on COUT has occurred or not.

8.2.4.11 **static void CMP_HAL_ClearOutputRisingFlag (CMP_Type * *base*) [inline], [static]**

This function clears the logic output rising edge event in the CMP module.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Register base address for the module. |
|-------------|---------------------------------------|

8.3 CMP Peripheral Driver

8.3.1 Overview

This section describes the programming interface of the CMP Peripheral driver. The CMP peripheral driver configures the CMP (Comparator). It handles initialization and configuration of CMP module.

8.3.2 CMP Driver model building

CMP driver has three parts:

- Basic Comparator - This part handles the mechanism that compares the voltage from the two input channels and outputs the assertion if the plus side voltage is higher than the minus side voltage.
- Internal 6-bit DAC - The internal 6-bit DAC can be configured as one of the input channel for the basic comparator. It can provide a reference voltage level when comparing with the other voltage signal.
- Sample/Filter - The Sample/Filter is an additional feature to improve the signal of the comparator's output. A sample clock, window mode and accumulation filter can be used to configure the Sample/Filter. When configuring the Sample/Filter, limited setting are available. See the "cmp_sample_filter_mode_t" definition in the "fsl_cmp_driver.h" file, or a chip reference manual for detailed information.

APIs are separate for each part and can be customized according to the application requirements.

8.3.3 CMP Call diagram

1. Ensure that the pin mux settings are ready before using the driver.
2. Call the "CMP_DRV_Init()" function to initialize the basic comparator. A configuration structure "cmp_user_config_t" type is required to hold the initialization information. The structure is populated by the application for a specific case, or by the "CMP_DRV_StructInitUserConfigDefault" API with available settings. A memory block is required and should be represented as a variable of the "cmp_state_t" type to keep state with the [CMP_DRV_Init\(\)](#) function.
3. Optionally, call the "CMP_DRV_EnableDac()" function to configure the internal 6-bit DAC if it is used as one of the input channels. A configuration structure of the "cmp_dac_config_t" type is required.
4. Optionally, call the "CMP_DRV_ConfigSampleFilter()" function to configure the Sample/Filter. A configuration structure of the "cmp_sample_filter_config_t" type is required to keep the configuration.
5. Optionally, call the "CMP_DRV_InstallCallback" function to install the user-defined callback function into the interrupt routine service. When the CMP is configured to enable the interrupt, the installed callback function is called after the interrupt event occurs.
6. Finally, the CMP automatically responds to the external events.

This is an example to initialize and configure the CMP driver for typical use cases.

CMP Peripheral Driver

```

// cmp_test.c //

#include <stdint.h>
#include <stdbool.h>
#include <stdio.h>
#include "fsl_cmp_driver.h"
#include <board.h>
#include "fsl_device_registers.h"
#include "fsl_os_abstraction.h"

#define TEST_CMP_INSTANCE    BOARD_CMP_INSTANCE
#define TEST_TIME_OUT_MS    (4000U)

```

Data Structures

- struct `cmp_state_t`
Internal driver state information. *More...*

Enumerations

- enum `cmp_flag_t` {
`kCmpFlagOfCoutRising = 0U,`
`kCmpFlagOfCoutFalling = 1U }`
Defines type of flags for the CMP event.

CMP Peripheral Driver

Functions

- `cmp_status_t CMP_DRV_StructInitUserConfigDefault (cmp_comparator_config_t *userConfigPtr, cmp_chn_mux_mode_t plusInput, cmp_chn_mux_mode_t minusInput)`
Populates the initial user configuration with default settings.
- `cmp_status_t CMP_DRV_Init (uint32_t instance, cmp_state_t *userStatePtr, const cmp_comparator_config_t *userConfigPtr)`
Initializes the CMP module.
- `cmp_status_t CMP_DRV_Deinit (uint32_t instance)`
De-initializes the CMP module.
- `void CMP_DRV_Start (uint32_t instance)`
Starts the CMP module.
- `void CMP_DRV_Stop (uint32_t instance)`
Stops the CMP module.
- `cmp_status_t CMP_DRV_ConfigDacChn (uint32_t instance, const cmp_dac_config_t *dacConfigPtr)`
Enables the internal DAC in the CMP module.
- `cmp_status_t CMP_DRV_ConfigSampleFilter (uint32_t instance, const cmp_sample_filter_config_t *configPtr)`
Configures the Sample feature in the CMP module.
- `bool CMP_DRV_GetOutputLogic (uint32_t instance)`
Gets the output of the CMP module.
- `bool CMP_DRV_GetFlag (uint32_t instance, cmp_flag_t flag)`
Gets the state of the CMP module.
- `void CMP_DRV_ClearFlag (uint32_t instance, cmp_flag_t flag)`
Clears the event record of the CMP module.

Variables

- `CMP_Type *const g_cmpBase []`
Table of base addresses for CMP instances.
- `const IRQn_Type g_cmpIrqId [CMP_INSTANCE_COUNT]`
Table to save CMP IRQ enumeration numbers defined in CMSIS header file.

8.3.4 Data Structure Documentation

8.3.4.1 struct cmp_state_t

The contents of this structure are internal to the driver and should not be modified by users. Also, contents of the structure are subject to change in future releases.

8.3.5 Enumeration Type Documentation

8.3.5.1 enum cmp_flag_t

Enumerator

- kCmpFlagOfCoutRising* Identifier to indicate if the COUT change from logic zero to one.
- kCmpFlagOfCoutFalling* Identifier to indicate if the COUT change from logic one to zero.

8.3.6 Function Documentation

8.3.6.1 cmp_status_t CMP_DRV_StructInitUserConfigDefault (cmp_comparator_config_t * userConfigPtr, cmp_chn_mux_mode_t plusInput, cmp_chn_mux_mode_t minusInput)

This function populates the initial user configuration with default settings. The default settings enable the CMP module to operate as a comparator. The settings are :

- .hysteresisMode = kCmpHysteresisOfLevel0
- .pinoutEnable = true
- .pinoutUnfilteredEnable = true
- .invertEnable = false
- .highSpeedEnable = false
- .dmaEnable = false
- .risingIntEnable = false
- .fallingIntEnable = false
- .triggerEnable = false However, it is still recommended to fill some fields of structure such as channel mux according to the application requirements. Note that this function does not set the configuration to hardware.

Parameters

| | |
|----------------------|---|
| <i>userConfigPtr</i> | Pointer to structure of configuration. See "cmp_user_config_t". |
| <i>plusInput</i> | Plus Input mux selection. See "cmp_chn_mux_mode_t". |
| <i>minusInput</i> | Minus Input mux selection. See "cmp_chn_mux_mode_t". |

CMP Peripheral Driver

Returns

Execution status.

8.3.6.2 `cmp_status_t CMP_DRV_Init (uint32_t instance, cmp_state_t * userStatePtr,
const cmp_comparator_config_t * userConfigPtr)`

This function initializes the CMP module, enables the clock, and sets the interrupt switcher. The CMP module is configured as a basic comparator.

Parameters

| | |
|----------------------|---|
| <i>instance</i> | CMP instance ID. |
| <i>userStatePtr</i> | Pointer to structure of context. See "cmp_state_t". |
| <i>userConfigPtr</i> | Pointer to structure of configuration. See "cmp_user_config_t". |

Returns

Execution status.

8.3.6.3 **cmp_status_t** CMP_DRV_Deinit (uint32_t *instance*)

This function de-initializes the CMP module. It shuts down the CMP clock and disables the interrupt. This API should be called when CMP is no longer used in the application. It also reduces power consumption.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | CMP instance ID. |
|-----------------|------------------|

Returns

Execution status.

8.3.6.4 **void** CMP_DRV_Start (uint32_t *instance*)

This function starts the CMP module. The configuration does not take effect until the module is started.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | CMP instance ID. |
|-----------------|------------------|

8.3.6.5 **void** CMP_DRV_Stop (uint32_t *instance*)

This function stops the CMP module. Note that this function does not shut down the module, but only pauses the features.

CMP Peripheral Driver

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | CMP instance ID. |
|-----------------|------------------|

8.3.6.6 `cmp_status_t CMP_DRV_ConfigDacChn (uint32_t instance, const cmp_dac_config_t * dacConfigPtr)`

This function enables the internal DAC in the CMP module. It takes effect only when the internal DAC has been chosen as an input channel for the comparator. Then, the DAC channel can be programmed to provide a reference voltage level.

Parameters

| | |
|---------------------|--|
| <i>instance</i> | CMP instance ID. |
| <i>dacConfigPtr</i> | Pointer to structure of configuration. See "cmp_dac_config_t". |

Returns

Execution status.

8.3.6.7 `cmp_status_t CMP_DRV_ConfigSampleFilter (uint32_t instance, const cmp_sample_filter_config_t * configPtr)`

This function configures the CMP working in Sample modes. These modes are advanced features in addition to the basic comparator such as Window Mode, Filter Mode, etc. See "cmp_sample_filter_config_t" for detailed description.

Parameters

| | |
|------------------|---|
| <i>instance</i> | CMP instance ID. |
| <i>configPtr</i> | Pointer to a structure of configurations. See "cmp_sample_filter_config_t". |

Returns

Execution status.

8.3.6.8 `bool CMP_DRV_GetOutputLogic (uint32_t instance)`

This function gets the output of the CMP module. The output source depends on the configuration when initializing the comparator. When the `cmp_user_config_t.pinoutUnfilteredEnable` is false, the output is processed by the filter. Otherwise, the output is that the signal did not pass the filter.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | CMP instance ID. |
|-----------------|------------------|

Returns

Output logic's assertion. When not inverted, plus side > minus side, it is true.

8.3.6.9 bool CMP_DRV_GetFlag (uint32_t *instance*, cmp_flag_t *flag*)

This function gets the state of the CMP module. It returns if the indicated event has been detected.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | CMP instance ID. |
| <i>flag</i> | Represent events or states. See "cmp_flag_t". |

Returns

Assertion if indicated event occurs.

8.3.6.10 void CMP_DRV_ClearFlag (uint32_t *instance*, cmp_flag_t *flag*)

This function clears the event record of the CMP module.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | CMP instance ID. |
| <i>flag</i> | Represent events or states. See "cmp_flag_t". |

8.3.7 Variable Documentation

8.3.7.1 CMP_Type* const g_cmpBase[]

8.3.7.2 const IRQn_Type g_cmplrqld[CMP_INSTANCE_COUNT]

Chapter 9 Carrier Modulator Transmitter (CMT)

9.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the CMT block of Kinetis devices.

Modules

- [CMT HAL driver](#)
- [CMT Peripheral driver](#)

CMT HAL driver

9.2 CMT HAL driver

9.2.1 Overview

This section describes the programming interface of the CMT HAL driver.

Enumerations

- enum `cmt_status_t`
Error codes for the CMT driver.
- enum `cmt_mode_t` {
`kCMTDirectIROCtl` = 0x00U,
`kCMTTimeMode` = 0x01U,
`kCMTFSKMode` = 0x05U,
`kCMTBasebandMode` = 0x09U }
The modes of CMT.
- enum `cmt_int_t` {
`kCMTModeBitMask` = 0x0DU,
`kCMTModulCountMask` = 0xFFFF }
The CMT macro definition for a specific value.
- enum `cmt_primary_clkdiv_t` {
`kCMTPriClkDiv1` = 0U,
`kCMTPriClkDiv2` = 1U,
`kCMTPriClkDiv3` = 2U,
`kCMTPriClkDiv4` = 3U,
`kCMTPriClkDiv5` = 4U,
`kCMTPriClkDiv6` = 5U,
`kCMTPriClkDiv7` = 6U,
`kCMTPriClkDiv8` = 7U,
`kCMTPriClkDiv9` = 8U,
`kCMTPriClkDiv10` = 9U,
`kCMTPriClkDiv11` = 10U,
`kCMTPriClkDiv12` = 11U,
`kCMTPriClkDiv13` = 12U,
`kCMTPriClkDiv14` = 13U,
`kCMTPriClkDiv15` = 14U,
`kCMTPriClkDiv16` = 15U }
The CMT clock divide primary prescaler.
- enum `cmt_second_clkdiv_t` {
`kCMTSecClkDiv1` = 0U,
`kCMTSecClkDiv2` = 1U,
`kCMTSecClkDiv4` = 2U,
`kCMTSecClkDiv8` = 3U }
The CMT clock divide secondary prescaler.
- enum `cmt_iro_polarity_t` {
`kCMTIROActiveLow` = 0U,

`kCMTIROActiveHigh = 1U }`

The CMT output polarity.

- enum `cmt_iro_ctl_t` {

`kCMTIROCtlLow = 0U,`

`kCMTIROCtlHigh = 1U }`

The CMT IRO latch control.

Initialization

- void `CMT_HAL_Init` (CMT_Type *base)
Initializes the CMT module.
- static void `CMT_HAL_SetMode` (CMT_Type *base, `cmt_mode_t` mode)
Selects the mode for CMT.
- `cmt_mode_t` `CMT_HAL_GetMode` (CMT_Type *base)
Gets the mode of the CMT module.
- static void `CMT_HAL_EnableExtendSpace` (CMT_Type *base)
Enables the extended space operation for the CMT modulator.
- static void `CMT_HAL_DisableExtendSpace` (CMT_Type *base)
Disables the extended space operation for the CMT modulator.
- static bool `CMT_HAL_IsExtendSpace` (CMT_Type *base)
Finds out whether the extended space feature is enabled.

Counters

- static void `CMT_HAL_SetCGCountOne` (CMT_Type *base, uint32_t highCount, uint32_t lowCount)
Sets the primary data set for the CMT carrier generator counter.
- static void `CMT_HAL_SetCGCountTwo` (CMT_Type *base, uint32_t highCount, uint32_t lowCount)
Sets the secondary data set for the CMT carrier generator counter.
- static void `CMT_HAL_SetModulateMarkCount` (CMT_Type *base, uint32_t markCount)
Sets the modulation mark time period for the CMT modulator counter.
- static void `CMT_HAL_SetModulateSpaceCount` (CMT_Type *base, uint32_t spaceCount)
Sets the modulation space time period for the CMT modulator counter.

Clock divider

- static void `CMT_HAL_SetClkByDiv` (CMT_Type *base, `cmt_primary_clkdiv_t` ppsDiv, `cmt_second_clkdiv_t` spsDiv)
Configures the CMT clock by setting the clock divider.
- static `cmt_primary_clkdiv_t` `CMT_HAL_GetPriClkDiv` (CMT_Type *base)
Gets the CMT primary clock divider.
- static `cmt_second_clkdiv_t` `CMT_HAL_GetSecClkDiv` (CMT_Type *base)
Gets the CMT secondary clock divider.

CMT HAL driver

Interrupt and DMA

- static void [CMT_HAL_SetIntCmd](#) (CMT_Type *base, bool enable)
Enables or disables the CMT end of cycle interrupt.
- static bool [CMT_HAL_GetIntCmd](#) (CMT_Type *base)
Gets whether the CMT end of cycle interrupt is enabled or not.
- static bool [CMT_HAL_IsEndofCycle](#) (CMT_Type *base)
Reads the end of cycle status flag.
- static void [CMT_HAL_SetDMACmd](#) (CMT_Type *base, bool enable)
Enables or disables the DMA.
- static bool [CMT_HAL_GetDMACmd](#) (CMT_Type *base)
Gets whether the DMA is enabled or not.

Output signal Control

- static void [CMT_HAL_SetIroPol](#) (CMT_Type *base, [cmt_iro_polarity_t](#) polarVal)
Controls the CMT output signal polarity.
- static void [CMT_HAL_SetIroCmd](#) (CMT_Type *base, bool enable)
Enables or disables the IRO signal.
- static void [CMT_HAL_SetIroCtl](#) (CMT_Type *base, [cmt_iro_ctl_t](#) ctlVal)
Controls the IRO latch.
- static bool [CMT_HAL_GetIrolatchState](#) (CMT_Type *base)
Reads the states of the IRO latch.

9.2.2 Enumeration Type Documentation

9.2.2.1 enum cmt_mode_t

Enumerator

kCMTDirectIROCtl Carrier modulator is disabled and the IRO signal is directly in software control.

kCMTTimeMode Carrier modulator is enabled in time mode.

kCMTFSKMode Carrier modulator is enabled in FSK mode.

kCMTBasebandMode Carrier modulator is enabled in baseband mode.

9.2.2.2 enum cmt_int_t

Enumerator

kCMTModeBitMask CMT mode bit mask.

kCMTModulCountMask CMT modulator count mask.

9.2.2.3 enum cmt_primary_clkdiv_t

Enumerator

- kCMTPriClkDiv1* The intermediate frequency is the bus clock divided by 1.
- kCMTPriClkDiv2* The intermediate frequency is the bus clock divided by 2.
- kCMTPriClkDiv3* The intermediate frequency is the bus clock divided by 3.
- kCMTPriClkDiv4* The intermediate frequency is the bus clock divided by 4.
- kCMTPriClkDiv5* The intermediate frequency is the bus clock divided by 5.
- kCMTPriClkDiv6* The intermediate frequency is the bus clock divided by 6.
- kCMTPriClkDiv7* The intermediate frequency is the bus clock divided by 7.
- kCMTPriClkDiv8* The intermediate frequency is the bus clock divided by 8.
- kCMTPriClkDiv9* The intermediate frequency is the bus clock divided by 9.
- kCMTPriClkDiv10* The intermediate frequency is the bus clock divided by 10.
- kCMTPriClkDiv11* The intermediate frequency is the bus clock divided by 11.
- kCMTPriClkDiv12* The intermediate frequency is the bus clock divided by 12.
- kCMTPriClkDiv13* The intermediate frequency is the bus clock divided by 13.
- kCMTPriClkDiv14* The intermediate frequency is the bus clock divided by 14.
- kCMTPriClkDiv15* The intermediate frequency is the bus clock divided by 15.
- kCMTPriClkDiv16* The intermediate frequency is the bus clock divided by 16.

9.2.2.4 enum cmt_second_clkdiv_t

Enumerator

- kCMTSecClkDiv1* The CMT clock is the intermediate frequency frequency divided by 1.
- kCMTSecClkDiv2* The CMT clock is the intermediate frequency frequency divided by 2.
- kCMTSecClkDiv4* The CMT clock is the intermediate frequency frequency divided by 4.
- kCMTSecClkDiv8* The CMT clock is the intermediate frequency frequency divided by 8.

9.2.2.5 enum cmt_iro_polarity_t

Enumerator

- kCMTIROActiveLow* The CMT IRO signal is active-low.
- kCMTIROActiveHigh* The CMT IRO signal is active-high.

9.2.2.6 enum cmt_iro_ctl_t

Enumerator

- kCMTIROCtlLow* The CMT IRO signal is controlled to low.
- kCMTIROCtlHigh* The CMT IRO signal is controlled to high.

CMT HAL driver

9.2.3 Function Documentation

9.2.3.1 void CMT_HAL_Init (CMT_Type * *base*)

This function initializes the CMT module. All control and data settings are cleared after initialization.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

**9.2.3.2 static void CMT_HAL_SetMode (CMT_Type * *base*, cmt_mode_t *mode*)
[inline], [static]**

This function selects the mode for CMT. The function is called during CMT initialization.

Parameters

| | |
|-------------|---|
| <i>base</i> | Base address for current CMT instance. |
| <i>mode</i> | Selection of CMT feature mode enumeration. See to "cmt_mode_t". |

9.2.3.3 cmt_mode_t CMT_HAL_GetMode (CMT_Type * *base*)

This function gets the mode of the CMT module .

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The mode of CMT module, See to "cmt_mode_t".

**9.2.3.4 static void CMT_HAL_EnableExtendSpace (CMT_Type * *base*) [inline],
[static]**

This function enables the extended space operation for the CMT modulator. It enlarges the space period for CMT and causes subsequent modulator cycles to be spaces for the duration of the modulator. It should be used in the CMT time, baseband, or FSK mode. This means it's valid when the CMT carrier generator and modulator is enabled.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

CMT HAL driver

9.2.3.5 `static void CMT_HAL_DisableExtendSpace (CMT_Type * base) [inline], [static]`

This function disables the extended space operation for the CMT modulator. It can be used to return the modulator to a standard operation when the extended space operation has been enabled.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

9.2.3.6 `static bool CMT_HAL_IsExtendSpace (CMT_Type * base) [inline], [static]`

This function finds out whether the extended space is enabled for the CMT modulator. When the carrier generator and modulator is enabled, this function can be used to check whether the extended space feature is opened or not.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for the current CMT instance. |
|-------------|--|

Returns

Current status of the extended space feature.

- true: the extended space feature is enabled.
- false: the extended space feature is disabled.

9.2.3.7 `static void CMT_HAL_SetCGCountOne (CMT_Type * base, uint32_t highCount, uint32_t lowCount) [inline], [static]`

This function sets the high time and low time of the primary data set for the CMT carrier generator counter to control the period and the duty cycle of the output carrier signal. If the CMT clock period is T_{cmt} , The period of the carrier generator signal equals $(highCount + lowCount) * T_{cmt}$. The duty cycle equals $highCount / (highCount + lowCount)$.

Parameters

| | |
|------------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>highCount</i> | The number of CMT clocks for carrier generator signal high time, integer in the range of 0 ~ 0xFF. |
| <i>lowCount</i> | The number of CMT clocks for carrier generator signal low time, integer in the range of 0 ~ 0xFF. |

9.2.3.8 static void CMT_HAL_SetCGCountTwo (CMT_Type * *base*, uint32_t *highCount*, uint32_t *lowCount*) [inline], [static]

This function sets the high time and low time of the secondary data set CMT carrier generator counter to control the period and the duty cycle of the output carrier signal. If the CMT clock period is T_{cmt} , The period of the carrier generator signal equals $(highCount + lowCount) * T_{cmt}$. The duty cycle equals $highCount / (highCount + lowCount)$. This data set is mainly used for FSK mode.

Parameters

| | |
|------------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>highCount</i> | The number of CMT clocks for carrier generator signal high time, integer in the range of 0 ~ 0xFF. |
| <i>lowCount</i> | The number of CMT clocks for carrier generator signal low time, integer in the range of 0 ~ 0xFF. |

9.2.3.9 static void CMT_HAL_SetModulateMarkCount (CMT_Type * *base*, uint32_t *markCount*) [inline], [static]

This function sets the mark time period of the CMT modulator counter to control the mark time of the output modulated signal from the carrier generator output signal. If the CMT clock frequency is F_{cmt} and the carrier out signal frequency is f_{cg} :

- In Time and Baseband mode: The mark period of the generated signal equals $(markCount + 1) / (F_{cmt}/8)$.
- In FSK mode: The mark period of the generated signal equals $(markCount + 1)/f_{cg}$.

Parameters

CMT HAL driver

| | |
|------------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>markCount</i> | The number of clock period for CMT modulator signal mark period, in the range of 0 ~ 0xFFFF. |

9.2.3.10 static void CMT_HAL_SetModulateSpaceCount (CMT_Type * *base*, uint32_t *spaceCount*) [inline], [static]

This function sets the mark time period of the CMT modulator counter to control the space time of the output modulated signal from the carrier generator output signal. If the CMT clock frequency is Fcmt and the carrier out signal frequency is fcg:

- In Time and Baseband mode: The space period of the generated signal equals $spaceCount / (Fcmt/8)$.
- In FSK mode: The space period of the generated signal equals $spaceCount/fcg$.

Parameters

| | |
|-------------------|---|
| <i>base</i> | Base address for current CMT instance. |
| <i>spaceCount</i> | The number of clock period for CMT modulator signal space period, in the range of 0 ~ 0xFFFF. |

9.2.3.11 static void CMT_HAL_SetClkByDiv (CMT_Type * *base*, cmt_primary_clkdiv_t *ppsDiv*, cmt_second_clkdiv_t *spsDiv*) [inline], [static]

There are two prescalers with 8 MHz or higher frequency in the clock divider block for the CMT flexible clock frequency generation from the bus clock.

Parameters

| | |
|---------------|---|
| <i>base</i> | Base address for current CMT instance. |
| <i>ppsDiv</i> | The primary prescaler divider. <i>ppsDiv</i> should be a integer range between 0 ~ 15 representing the divisor 1 ~ 16 (See "cmt_primary_clkdiv_t"). It divides the bus clock to generate the Intermediate Frequency clock. The Intermediate frequency (IF) clock should be approximately 8 MHz. For example, if the bus clock is 50 MHz, <i>ppsDiv</i> should be set to kCMTPriClkDivSix, then $IF = 50 \text{ MHz}/6 = 8.333.333\dots$. if the bus clock is 8 MHz, <i>ppsDiv</i> should be set to kCMTPriClkDivOne. |

| | |
|---------------|---|
| <i>spsDiv</i> | The secondary prescaler divider. The CMT carrier generator resolution is $8\text{Mhz}/(2^{\wedge} \text{spsDiv})$. <i>spsDiv</i> should be a integer range between 0 ~ 3 representing the divisor 1,2,4 and 8 (See "cmt_second_clkdiv_t"). |
|---------------|---|

**9.2.3.12 static cmt_primary_clkdiv_t CMT_HAL_GetPriClkDiv (CMT_Type * *base*)
[inline], [static]**

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The CMT primary clock divider.

**9.2.3.13 static cmt_second_clkdiv_t CMT_HAL_GetSecClkDiv (CMT_Type * *base*)
[inline], [static]**

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The CMT secondary clock divider.

**9.2.3.14 static void CMT_HAL_SetIntCmd (CMT_Type * *base*, bool *enable*) [inline],
[static]**

If enabled, an interrupt occurs at the end of the modulator cycle or when the CMT_HAL_IsEndofCycle returns true. (Note: NVIC should be called to enable the CMT interrupt on the system level).

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

CMT HAL driver

| | |
|---------------|---|
| <i>enable</i> | Enable or disable interrupt. <ul style="list-style-type: none"> • true: CPU interrupt is enabled. • false: CPU interrupt is disabled. |
|---------------|---|

9.2.3.15 static bool CMT_HAL_GetIntCmd (CMT_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

Status of enabled or disabled interrupt

- true: Interrupt is enabled.
- false: Interrupt is disabled.

9.2.3.16 static bool CMT_HAL_IsEndofCycle (CMT_Type * *base*) [inline], [static]

The flag is set:

- When the modulator is not currently active and carrier and modulator is set to start the initial CMT transmission.
- At the end of each modulation cycle when the counter is reloaded and the carrier and modulator are enabled.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

Current status of the end of cycle status flag

true: End-of-cycle has occurred.

- false: End-of-cycle has not yet occurred since the flag last cleared.

9.2.3.17 static void CMT_HAL_SetDMACmd (CMT_Type * *base*, bool *enable*) [inline], [static]

If enabled, a DMA transfer request occurs at the end of the modulator cycle when the end-of-cycle interrupt is enabled.

Parameters

| | |
|---------------|---|
| <i>base</i> | Base address for current CMT instance. |
| <i>enable</i> | Enable or disable DMA. <ul style="list-style-type: none"> • true: DMA transfer request and done are enabled. • false: DMA transfer request and done are disabled. |

9.2.3.18 static bool CMT_HAL_GetDMACmd (CMT_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

Status of enabled or disabled DMA

- true: DMA is enabled.
- false: DMA is disabled.

9.2.3.19 static void CMT_HAL_SetIroPol (CMT_Type * *base*, cmt_iro_polarity_t *polarVal*) [inline], [static]

Parameters

| | |
|-----------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>polarVal</i> | The polarity of the IRO signal. See "cmt_iro_polarity_t" |

9.2.3.20 static void CMT_HAL_SetIroCmd (CMT_Type * *base*, bool *enable*) [inline], [static]

This function enables and disables the IRO signal. When the IRO signal is enabled, it is an output that drives out either the CMT transmitter output or the state of IRO latch control depending on whether the carrier modulator is enabled.

CMT HAL driver

Parameters

| | |
|---------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>enable</i> | Enable or disable IRO signal. <ul style="list-style-type: none"> • true: The IRO signal is enabled. • false: The IRO signal is disabled. |

9.2.3.21 `static void CMT_HAL_SetIroCtl (CMT_Type * base, cmt_iro_ctl_t ctlVal) [inline], [static]`

This function changes the states of the IRO signal when the kCMTDirectIROMode mode is set and the IRO signal is enabled.

Parameters

| | |
|---------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>ctlVal</i> | The control of the IRO signal. See "cmt_iro_ctl_t" |

9.2.3.22 `static bool CMT_HAL_GetIrolatchState (CMT_Type * base) [inline], [static]`

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The states of the IRO latch

9.3 CMT Peripheral driver

9.3.1 Overview

This section describes the programming interface of the CMT Peripheral driver. The CMT driver configures and uses CMT hardware. It supports module initializations and CMT module configurations.

9.3.2 CMT Clock formulas

CMT clock frequency = $\text{bus_clock_Hz} / (\text{bus_clock_Hz} / 8 \text{ MHz}) / \text{cmtDivider}$

CMT carrier and generator frequency = CMT Clock frequency / (highCount1 + lowCount1) (In FSK mode, the second frequency = CMT Clock frequency / (highCount2 + lowCount2))

In Time and Baseband mode CMT IRO signal mark time = $(\text{markCount} + 1) / (\text{CMT Clock frequency} / 8)$

CMT IRO signal space time = $\text{spaceCount} / (\text{CMT Clock frequency} / 8)$

In FSK mode CMT IRO signal mark time = $(\text{markCount} + 1) / \text{CMT carrier and generator frequency}$

CMT IRO signal space time = $\text{spaceCount} / \text{CMT carrier and generator frequency}$

9.3.3 CMT Initialization

To initialize the CMT driver, define an `cmt_base_config_t` type variable and pass it in the `CMT_DRV_Init()` function. The initialize setting the CMT clock, interrupt and the IRO signal for the CMT module.

This is an example code to initialize and configure the driver:

```
// Define device configuration.
const cmt_base_config_t cmtInit = {
    isInterruptEnabled = enable, // Enable end of modulation cycle interrupt. //
    isIroEnabled = true,        // Enable the IRO signal. //
    iroPolarity = kCMTIROActiveHigh, // Set the IRO polarity active high. //
    cmtDivider = kCMTSecClkDiv1 // Set the secondary CMT clock divider to 1. //
};

// Initialize CMT instance 0.
CMT_DRV_Init(0, &cmtInit);
```

CMT Carrier generator and Modulator Start

To Start the CMT carrier and modulator, define an `cmt_modulate_config_t` type variable and pass it in the `CMT_DRV_StartCarrierModulate()` function. The carrier and modulation start configuring the CMT mode, generating protocol timing, or carrier signal data.

```
typedef struct CmtModulateConfig
{
    cmt_mode_t mode; // The modes for carrier and modulator enabled. kCMTDirectIROctl should
                    // not be used here. //
```

CMT Peripheral driver

```

uint8_t highCount1; // The high time period for the first counter of the CMT carrier generator. //
uint8_t lowCount1; // The low time period for the first counter of the CMT carrier generator. //
uint8_t highCount2; // The high time period for the second counter of the CMT carrier generator. //
uint8_t lowCount2; // The low time period for the second counter of the CMT carrier generator. //
uint16_t markCount; // The mark time period for the CMT modulator. //
uint16_t spaceCount; // The space time period for the CMT modulator. //
} cmt_modulate_config_t;

typedef struct CmtModulateData {
    uint8_t *data; // The data for modulation, the LSB was transmitted first. //
    uint32_t len; // The length of data bit for modulation. //
    uint32_t lenDone; // The length of data bit has been modulated. //
    uint16_t markOne; // The mark time for the data bit "1". //
    uint16_t spaceOne; // The space time for the data bit "1". //
    uint16_t markZero; // The mark time for the data bit "0". //
    uint16_t spaceZero; // The space time for the data bit "0". //
} cmt_modulate_data_t;

```

This is an example code to start the driver:

```

// Defines the CMT carrier and modulator configuration.
cmt_modulate_config_t modulateConfig = {
    mode = kCMTTimeMode, // Set the CMT Time mode. //
    highCount1 = 1, // Set the high time for the first count of CMT carrier generator. //
    lowCount1 = 1, // Set the low time for the first count of CMT carrier generator. //
    markCount = 9, // Set the count of modulator mark period. //
    spaceCount = 0, // Set the count of modulator space period. //
};
// Defines data to be transmitted
uint8_t newData[2] = {0x85, 0x14};
cmt_modulate_data_t modData = {
    .data = newData,
    .len = 15,
    .markOne = 8,
    .spaceOne = 0,
    .markZero = 0,
    .spaceZero = 8
};
// Start CMT instance 0 with LSB mode byte transmit.
CMT_DRV_StartCarrierModulate(0, &modulateConfig, &modData, false);

```

For the settings above, the IRO output signal is a 4 MHz signal with 50% duty cycle when the Bus clock is 48 MHz.

9.3.4 CMT DATA Modulate

The `CMT_DRV_ModulateDataByBit()` is provided to modulate data and should be called by the ISR handler.

When handling CMT initialization, define a global `cmt_modulate_data_t` type variable `modData`, define a `cmt_modulate_config_t` type variable, and define the MSB/LSB mode then pass it in the `CMT_DRV_StartCarrierModulate()` function.

After the data modulation is complete, call the void `CMT_DRV_StopCarrierModulate(uint32_t instance)` function to stop it at any time.

To close the CMT module entirely, call the `cmt_status_t CMT_DRV_Deinit(uint32_t instance)` function. This disables both the CMT carrier modulator and the clock gate.

Data Structures

- struct `cmt_base_config_t`
CMT configuration structure. [More...](#)
- struct `cmt_modulate_data_t`
CMT modulate data structure. [More...](#)
- struct `cmt_modulate_config_t`
CMT modulate configure structure. [More...](#)

Macros

- #define `CMT_INTERMEDIATEFREQUENCY_8MHZ` 8000000U
Define the standard intermediate frequency (IF)
- #define `CMT_MODULATEUNIT8BITS` 8U
Define the standard intermediate frequency (IF)

Variables

- CMT_Type *const `g_cmtBase` []
Table of base addresses for CMT instances.
- const IRQn_Type `g_cmtIrqId` []
Table to save CMT IRQ enumeration numbers defined in the CMSIS header file.

Initialization and Shutdown

- `cmt_status_t CMT_DRV_Init` (uint32_t instance, const `cmt_base_config_t` *config)
Initializes the CMT module.
- `cmt_status_t CMT_DRV_Deinit` (uint32_t instance)
Disables the CMT module and gate control.
- void `CMT_DRV_StartCarrierModulate` (uint32_t instance, `cmt_modulate_config_t` *modulate-Config, `cmt_modulate_data_t` *cmtData, bool isMsbMode)
Starts the CMT carrier generator and modulator.
- void `CMT_DRV_StopCarrierModulate` (uint32_t instance)
Stops the CMT carrier generator and modulator.
- `cmt_status_t CMT_DRV_ModulateDataByBit` (uint32_t instance, `cmt_modulate_data_t` *cmtData, bool isMsbMode)
Modulates the data by one bit.
- void `CMT_DRV_SetMode` (uint32_t instance, `cmt_mode_t` mode)
Selects the mode for CMT.
- `cmt_mode_t CMT_DRV_GetMode` (uint32_t instance)
Gets the mode of CMT module.

CMT Peripheral driver

Clock divider

- void [CMT_DRV_SetClockDiv](#) (uint32_t instance, [cmt_second_clkdiv_t](#) spsDiv)
Sets CMT clock divider.

Interrupt

- bool [CMT_DRV_IsEndofCycle](#) (uint32_t instance)
Reads Reads the current end of cycle flag.
- void [CMT_DRV_ClearEndofCycleFlag](#) (uint32_t instance, uint32_t markCount)
Clears the end of cycle status flag.

Counters

- void [CMT_DRV_SetModulateMarkCount](#) (uint32_t instance, uint32_t markCount)
Sets the modulation mark time period for the CMT modulator counter.
- void [CMT_DRV_SetModulateSpaceCount](#) (uint32_t instance, uint32_t spaceCount)
Sets the modulation space time period for the CMT modulator counter.

Output signal Control

- void [CMT_DRV_SetIroCtl](#) (uint32_t instance, [cmt_iro_ctl_t](#) ctlVal)
IRO Latch Control.
- bool [CMT_DRV_GetIrolatchState](#) (uint32_t instance)
Read the states of IRO latch.

9.3.5 Data Structure Documentation

9.3.5.1 struct [cmt_base_config_t](#)

Defines a basic configure structure [CmtBaseConfig](#) and uses the [CMT_DRV_Init\(\)](#) function to make necessary initializations.

Data Fields

- bool [isInterruptEnabled](#)
Timer interrupt 0-disabled/1-enable.
- bool [isIroEnabled](#)
The IRO output 0-disabled/1-enabled.
- [cmt_iro_polarity_t](#) [iroPolarity](#)
The IRO polarity.
- [cmt_second_clkdiv_t](#) [cmtDivider](#)
The CMT clock divide prescaler.

9.3.5.2 struct cmt_modulate_data_t

Defines a data structure for CMT data modulation.

9.3.5.3 struct cmt_modulate_config_t

Defines a specific configuration structure CmtModulateConfig and uses the [CMT_DRV_StartCarrier-Modulate\(\)](#) function to initialize and start carrier generator and modulator. Stores the transmitted data information to the global variable for data modulation.

Data Fields

- [cmt_mode_t mode](#)
< Choose these mode for carrier and modulator enabled, kCMTDirectIROctl should not used here

9.3.5.3.0.7 Field Documentation

9.3.5.3.0.7.1 cmt_mode_t cmt_modulate_config_t::mode

The high and low time for the carrier signal

9.3.6 Function Documentation

9.3.6.1 cmt_status_t CMT_DRV_Init (uint32_t instance, const cmt_base_config_t * config)

This function must be called before calling all the other CMT driver functions. This function ungates the CMT clock and sets the CMT clock, interrupt, and output signal for CMT module. Pass in its basic configuration structure.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | CMT module instance number. |
| <i>config</i> | The CMT basic configuration structure. |

Returns

Error or success status returned by API.

9.3.6.2 cmt_status_t CMT_DRV_Deinit (uint32_t instance)

This function disables all CMT interrupts and CMT clock. It, then, gates the CMT clock control. CMT_DRV_Init must be called if you want to use CMT again.

CMT Peripheral driver

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | CMT module instance number. |
|-----------------|-----------------------------|

Returns

Error or success status returned by API.

9.3.6.3 void CMT_DRV_StartCarrierModulate (uint32_t *instance*, cmt_modulate_config_t * *modulateConfig*, cmt_modulate_data_t * *cmtData*, bool *isMsbMode*)

This function un-gates the CMT carrier generator and modulator clock, initializes, and starts the modulator and carrier generator. Pass in the modulation specific configuration structure. CMT_DRV_Init should be called before using this function.

Parameters

| | |
|------------------------|---|
| <i>instance</i> | CMT module instance number. |
| <i>modulate-Config</i> | The CMT modulator specific configuration structure. |
| <i>cmtData</i> | The data to be modulated. |
| <i>isMsbMode</i> | The MSB or LSB mode for the byte transmit <ul style="list-style-type: none"> • true, The MSB mode. • false, The LSB mode. |

9.3.6.4 void CMT_DRV_StopCarrierModulate (uint32_t *instance*)

This function stops and disables the CMT carrier generator and modulator. When the CMT carrier generator and modulator is disabled the IRO signal can be controlled directly by calling the CMT_DRV_Set-IroCtl.

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | CMT module instance number. |
|-----------------|-----------------------------|

9.3.6.5 cmt_status_t CMT_DRV_ModulateDataByBit (uint32_t *instance*, cmt_modulate_data_t * *cmtData*, bool *isMsbMode*)

This function can be called by the CMT ISR handler to handle data modulation by using ISR handler to change the modulation mark and space time period according to the data bit "1" or bit "0" each time. Note:

the modulation updates the mark and space time period at the end of every modulation cycle, irrespective of interrupt handling. To update the new mark and space time period in time, this function should be processed in one modulation cycle. When tested for Bare Metal, the function called by the ISR handler takes about 4 μ s and the maximum bit rate is about 250000.

Parameters

| | |
|------------------|--|
| <i>instance</i> | CMT module instance number. |
| <i>cmtData</i> | The data to be modulated. |
| <i>isMsbMode</i> | The MSB or LSB mode for the byte transmit. <ul style="list-style-type: none"> • true, The MSB mode. • false, The LSB mode. |

9.3.6.6 void CMT_DRV_SetMode (uint32_t *instance*, cmt_mode_t *mode*)

This function selects the mode for CMT.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
| <i>mode</i> | Selection of CMT feature mode enumeration. See to "cmt_mode_t" |

9.3.6.7 cmt_mode_t CMT_DRV_GetMode (uint32_t *instance*)

This function gets the mode of CMT module.

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The mode of CMT module. See to "cmt_mode_t".

9.3.6.8 void CMT_DRV_SetClockDiv (uint32_t *instance*, cmt_second_clkdiv_t *spsDiv*)

This function sets the CMT clock divider.

CMT Peripheral driver

Parameters

| | |
|-----------------|---|
| <i>instance</i> | CMT module instance number. |
| <i>spsDiv</i> | The CMT clock divider prescaler. The CMT carrier generator resolution is 8 Mhz/(2 [^] spsDiv) . spsDiv should be a integer range between 0 ~ 3 representing the divisor 1,2,4 and 8 (See "cmt_second_clkdiv_t"). |

9.3.6.9 bool CMT_DRV_IsEndofCycle (uint32_t instance)

This flag is set at the end of each cycle.

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | CMT module instance number. |
| <i>channel</i> | Timer channel number |

Returns

The status of the end of cycle flag

- true: The end of cycle has occurred.
- false: The end of cycle has not yet occurred.

9.3.6.10 void CMT_DRV_ClearEndofCycleFlag (uint32_t instance, uint32_t markCount)

Clears the end of cycle status flag by reading the MSC followed by and access of the lower eight bit of the modulator mark or space counter. Note that this is not for clearing the end of cycle status flag when the CMT DMA is enabled.

Parameters

| | |
|------------------|--|
| <i>instance</i> | CMT module instance number. |
| <i>markCount</i> | The number of clock period for CMT modulator signal mark period, in the range of 0 ~ 0xFFFF. |

9.3.6.11 void CMT_DRV_SetModulateMarkCount (uint32_t instance, uint32_t markCount)

This function sets the mark time period of the CMT modulator counter to control the mark time of the output modulated signal from the carrier generator output signal. If the CMT clock frequency is F_{cmt} and the carrier out signal frequency is f_{cg}:

- In Time and Baseband mode: The mark period of the generated signal equals $(\text{markCount} + 1) / (\text{Fcmt}/8)$.
- In FSK mode: The mark period of the generated signal equals $(\text{markCount} + 1) / \text{fcg}$.

Parameters

| | |
|------------------|--|
| <i>instance</i> | CMT module instance number. |
| <i>markCount</i> | The number of clock period for CMT modulator signal mark period, in the range of 0 ~ 0xFFFF. |

9.3.6.12 void CMT_DRV_SetModulateSpaceCount (uint32_t instance, uint32_t spaceCount)

This function sets the mark time period of the CMT modulator counter to control the space time of the output modulated signal from the carrier generator output signal. If the CMT clock frequency is Fcmt and the carrier out signal frequency is fcg:

- In Time and Baseband mode: The space period of the generated signal equals $\text{spaceCount} / (\text{Fcmt}/8)$.
- In FSK mode: The space period of the generated signal equals $\text{spaceCount} / \text{fcg}$.

Parameters

| | |
|-------------------|---|
| <i>instance</i> | CMT module instance number. |
| <i>spaceCount</i> | The number of clock period for CMT modulator signal space period, in the range of 0 ~ 0xFFFF. |

9.3.6.13 void CMT_DRV_SetIroCtl (uint32_t instance, cmt_iro_ctl_t ctlVal)

Changes the states of the IRO signal when the kCMTDirectIROMode mode is set and the IRO signal is enabled.

Parameters

| | |
|---------------|---|
| <i>base</i> | Base address for current CMT instance. |
| <i>ctlVal</i> | The control of the IRO signal. See "_cmt_iro_ctl_t" |

9.3.6.14 bool CMT_DRV_GetIrolatchState (uint32_t instance)

CMT Peripheral driver

Parameters

| | |
|-------------|--|
| <i>base</i> | Base address for current CMT instance. |
|-------------|--|

Returns

The states of the IRO latch

9.3.7 Variable Documentation

9.3.7.1 CMT_Type* const g_cmtBase[]

Chapter 10

Computer Operating Properly (COP) Watchdog Timer

10.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the COP Watchdog Timer (WDOG) block of Kinetis devices.

Modules

- [COP HAL driver](#)
- [COP Peripheral Driver](#)

COP HAL driver

10.2 COP HAL driver

10.2.1 Overview

The section describes the programming interface of the COP HAL driver.

Data Structures

- struct `cop_config_t`
Data structure to initialize the COP. [More...](#)

Enumerations

- enum `cop_clock_source_t` {
 `kCopLpoClock`,
 `kCopBusClock` }
COP clock source selection.
- enum `cop_timeout_cycles_t` {
 `kCopTimeout_short_2to5_or_long_2to13` = 1U,
 `kCopTimeout_short_2to8_or_long_2to16` = 2U,
 `kCopTimeout_short_2to10_or_long_2to18` = 3U }
Define the value of the COP timeout cycles.
- enum `cop_status_t` {
 `kStatus_COP_Success` = 0x0U,
 `kStatus_COP_Fail` = 0x01,
 `kStatus_COP_NotInitialized` = 0x2U,
 `kStatus_COP_NullArgument` = 0x3U }
cop status return codes.

COP HAL.

- void `COP_HAL_SetConfig` (SIM_Type *base, const `cop_config_t` *configPtr)
Configures the COP Watchdog.
- static void `COP_HAL_Enable` (void)
Enables the COP Watchdog.
- static void `COP_HAL_Disable` (SIM_Type *base)
Disables the COP Watchdog.
- static bool `COP_HAL_IsEnable` (SIM_Type *base)
Determines whether the COP is enabled.
- static void `COP_HAL_Refresh` (SIM_Type *base)
Servicing the COP Watchdog.
- static void `COP_HAL_ResetSystem` (SIM_Type *base)
Resets the system.
- void `COP_HAL_Init` (SIM_Type *base)
Restores the COP module to the reset value.

10.2.2 Data Structure Documentation

10.2.2.1 struct cop_config_t

This structure is used to initialize the COP during the cop_init function call. It contains all COP configurations.

Data Fields

- bool [copWindowModeEnable](#)
Set COP watchdog run mode—Window mode or Normal mode.
- [cop_clock_source_t](#) [copClockSource](#)
Set COP watchdog clock source.
- [cop_timeout_cycles_t](#) [copTimeout](#)
Set COP watchdog timeout value.

10.2.3 Enumeration Type Documentation

10.2.3.1 enum cop_clock_source_t

Enumerator

- kCopLpoClock* LPO clock, 1K HZ.
- kCopBusClock* BUS clock.

10.2.3.2 enum cop_timeout_cycles_t

Enumerator

- kCopTimeout_short_2to5_or_long_2to13* 2 to 5 clock cycles when clock source is LPO or in short timeout mode otherwise 2 to 13 clock cycles
- kCopTimeout_short_2to8_or_long_2to16* 2 to 8 clock cycles when clock source is LPO or in short timeout mode otherwise 2 to 16 clock cycles
- kCopTimeout_short_2to10_or_long_2to18* 2 to 10 clock cycles when clock source is LPO or in short timeout mode otherwise 2 to 18 clock cycles

10.2.3.3 enum cop_status_t

Enumerator

- kStatus_COP_Success* COP operation Succeed.
- kStatus_COP_Fail* COP operation Failed.
- kStatus_COP_NotInitialized* COP is not initialized yet.
- kStatus_COP_NullArgument* Argument is NULL.

COP HAL driver

10.2.4 Function Documentation

10.2.4.1 void COP_HAL_SetConfig (SIM_Type * *base*, const cop_config_t * *configPtr*)

The COP control register is write once after reset.

Parameters

| | |
|------------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
| <i>configPtr</i> | configure COP control register |

10.2.4.2 static void COP_HAL_Enable (void) [inline], [static]

After reset the COP is enabled.

10.2.4.3 static void COP_HAL_Disable (SIM_Type * base) [inline], [static]

This function disables the COP Watchdog and should be called after reset if your application does not need the COP Watchdog.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
|-------------|---------------------------------|

10.2.4.4 static bool COP_HAL_IsEnable (SIM_Type * base) [inline], [static]

This function checks whether the COP is running.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
|-------------|---------------------------------|

Returns

State of the module

Return values

| | |
|--------------|-----------------|
| <i>true</i> | COP is enabled |
| <i>false</i> | COP is disabled |

10.2.4.5 static void COP_HAL_Refresh (SIM_Type * base) [inline], [static]

This function resets the COP timeout by writing 0x55 then 0xAA. Writing any other value generates a system reset. The writing operations should be atomic.

COP HAL driver

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
|-------------|---------------------------------|

10.2.4.6 static void COP_HAL_ResetSystem (SIM_Type * *base*) [inline], [static]

This function resets the system.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
|-------------|---------------------------------|

10.2.4.7 void COP_HAL_Init (SIM_Type * *base*)

This function restores the COP module to the reset value.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The COP peripheral base address |
|-------------|---------------------------------|

10.3 COP Peripheral Driver

10.3.1 Overview

The section describes the programming interface of the COP Peripheral driver. The COP driver configures the COP and provides a simple way to initialize and configure the COP.

10.3.2 COP Initialization

To initialize the COP module, call the `COP_DRV_Init()` function and pass in the user configuration structure. This function automatically enables the COP module and clock.

After the `COP_DRV_Init()` function is called, the COP is enabled and its counter is working. Therefore, the `COP_DRV_Refresh()` function should be called before the COP times out.

This example code shows how to initialize and configure the driver:

```
// Define device configuration.
cop_user_config_t copInit =
{
    .copWindowModeEnable = (uint8_t>false,           //Disable COP window mode
#if FSL_FEATURE_COP_HAS_LONGTIME_MODE
    .copTimeoutMode      = kCopShortTimeoutMode,    //configure COP timeout mode
#else
    .copClockSelect      = kCopLpoClock,           //configure COP clock
    source
#endif
    .copTimeout          = kCopTimeout_short_2to5_or_long_2to13, //
    configure COP timeout cycles
#if FSL_FEATURE_COP_HAS_LONGTIME_MODE
    .copStopModeEnable   = (uint8_t>false,         //Disable COP in stop mode
    .copDebugModeEnable  = (uint8_t>false,         //Disable COP in debug mode
    .copClockSource      = kCopLpoClock,         //configure COP clock
    source
#endif
};

// Initialize COP.
COP_DRV_Init(instance, &init);
```

10.3.3 COP Refresh

After the COP is enabled, the `COP_DRV_Refresh()` function should be called periodically to prevent the COP from timing out.

Otherwise, a reset is asserted. This is called the "Feed Dog".

10.3.4 COP Reset Count

The COP can reset the system.

1. After `COP_DRV_Reset()`, the chip is be reset.

COP Peripheral Driver

Variables

- `SIM_Type *const g_copBase []`
Table of base addresses for COP instances.

COP Driver

- `cop_status_t COP_DRV_Init (uint32_t instance, const cop_config_t *initPtr)`
Initializes the COP.
- `void COP_DRV_Disable (uint32_t instance)`
Disables the COP Watchdog.
- `void COP_DRV_Refresh (uint32_t instance)`
Resets the COP timeout counter.
- `bool COP_DRV_IsRunning (uint32_t instance)`
Gets the COP running status.
- `void COP_DRV_ResetSystem (uint32_t instance)`
Resets the system.

10.3.5 Function Documentation

10.3.5.1 `cop_status_t COP_DRV_Init (uint32_t instance, const cop_config_t * initPtr)`

This function initializes the COP. After it is called, the COP starts running according to the configuration. Because all COP control registers are write-once only, the `cop_init` function and the `cop_shutdown` function can be called only once. A second call has no effect.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The COP peripheral instance number. |
| <i>initPtr</i> | COP Initialize data structure. |

Returns

The initialization status.

10.3.5.2 `void COP_DRV_Disable (uint32_t instance)`

This function disables the COP Watchdog. Note: The COP configuration register is write-once after reset. To disable the COP Watchdog, call this function first.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The COP peripheral instance number. |
|-----------------|-------------------------------------|

10.3.5.3 void COP_DRV_Refresh (uint32_t *instance*)

This function feeds the COP. It sets the COP timer count to zero and should be called before the COP timer expires. Otherwise, a RESET is asserted.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The COP peripheral instance number. |
|-----------------|-------------------------------------|

10.3.5.4 bool COP_DRV_IsRunning (uint32_t *instance*)

This function gets the COP running status.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The COP peripheral instance number. |
|-----------------|-------------------------------------|

Returns

COP running status; 0 means not running; 1 means running

10.3.5.5 void COP_DRV_ResetSystem (uint32_t *instance*)

This function resets the device.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | The COP peripheral instance number. |
|-----------------|-------------------------------------|

10.3.6 Variable Documentation

10.3.6.1 SIM_Type* const g_copBase[]

Chapter 11

Cyclic Redundancy Check (CRC)

11.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Cyclic Redundancy Check (CRC) module of Kinetis devices.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection. The CRC module provides a programmable polynomial, seed, and other parameters required to implement a 16-bit or 32-bit CRC standard. The 16/32-bit code is calculated for 32 bits of data at a time.

Modules

- [CRC HAL driver](#)
- [CRC driver](#)

CRC HAL driver

11.2 CRC HAL driver

11.2.1 Overview

This section describes the programming interface of the CRC HAL driver.

Files

- file [fsl_crc_hal.h](#)

Enumerations

- enum [crc_status_t](#) {
[kStatus_CRC_Success](#) = 0U,
[kStatus_CRC_InvalidArgument](#) = 1U,
[kStatus_CRC_Failed](#) = 2U }
Definitions
- enum [crc_transpose_t](#) {
[kCrcNoTranspose](#) = 0U,
[kCrcTransposeBits](#) = 1U,
[kCrcTransposeBoth](#) = 2U,
[kCrcTransposeBytes](#) = 3U }
Define type of enumerating transpose modes for CRC peripheral.
- enum [crc_prot_width_t](#) {
[kCrc16Bits](#) = 0U,
[kCrc32Bits](#) = 1U }
Define type of enumerating CRC protocol widths for CRC peripheral.

CRC-related feature APIs

API

- void [CRC_HAL_Init](#) (CRC_Type *base)
This function initializes the module to a known state.
- static uint32_t [CRC_HAL_GetDataReg](#) (CRC_Type *base)
Returns the current CRC result from the data register.
- static uint16_t [CRC_HAL_GetDataHReg](#) (CRC_Type *base)
Returns the upper 16 bits of the current CRC result from the data register.
- static uint16_t [CRC_HAL_GetDataLReg](#) (CRC_Type *base)
Returns the lower 16 bits of the current CRC result from the data register.
- static void [CRC_HAL_SetDataReg](#) (CRC_Type *base, uint32_t value)
Sets the CRC data register (4 bytes).
- static void [CRC_HAL_SetDataHReg](#) (CRC_Type *base, uint16_t value)
Sets the CRC data register (upper 2 bytes).
- static void [CRC_HAL_SetDataLReg](#) (CRC_Type *base, uint16_t value)

- Sets the CRC data register (lower 2 bytes).*

 - static void [CRC_HAL_SetDataHLReg](#) (CRC_Type *base, uint8_t value)

Sets the CRC data register (HL byte).

 - static void [CRC_HAL_SetDataHUReg](#) (CRC_Type *base, uint8_t value)

Sets the CRC data register (HU byte).

 - static void [CRC_HAL_SetDataLLReg](#) (CRC_Type *base, uint8_t value)

Sets the CRC data register (LL byte).

 - static void [CRC_HAL_SetDataLUReg](#) (CRC_Type *base, uint8_t value)

Sets the CRC data register (LU byte).

 - static uint32_t [CRC_HAL_GetPolyReg](#) (CRC_Type *base)

Returns the polynomial register value.

 - static uint16_t [CRC_HAL_GetPolyHReg](#) (CRC_Type *base)

Returns the upper 16 bits of polynomial register.

 - static uint16_t [CRC_HAL_GetPolyLReg](#) (CRC_Type *base)

Returns the lower 16 bits of polynomial register.

 - static void [CRC_HAL_SetPolyReg](#) (CRC_Type *base, uint32_t value)

Sets the polynomial register.

 - static void [CRC_HAL_SetPolyHReg](#) (CRC_Type *base, uint16_t value)

Sets the upper 16 bits of polynomial register.

 - static void [CRC_HAL_SetPolyLReg](#) (CRC_Type *base, uint16_t value)

Sets the lower 16 bits of polynomial register.

 - static uint32_t [CRC_HAL_GetCtrlReg](#) (CRC_Type *base)

Returns the CRC control register.

 - static void [CRC_HAL_SetCtrlReg](#) (CRC_Type *base, uint32_t value)

Sets the CRC control register.

 - static bool [CRC_HAL_GetSeedOrDataMode](#) (CRC_Type *base)

Gets the CRC seed mode.

 - static void [CRC_HAL_SetSeedOrDataMode](#) (CRC_Type *base, bool enable)

Sets the CRC seed mode.

 - static [crc_transpose_t](#) [CRC_HAL_GetWriteTranspose](#) (CRC_Type *base)

Gets the CRC transpose type for writes.

 - static void [CRC_HAL_SetWriteTranspose](#) (CRC_Type *base, [crc_transpose_t](#) transp)

Sets the CRC transpose type for writes.

 - static [crc_transpose_t](#) [CRC_HAL_GetReadTranspose](#) (CRC_Type *base)

Gets the CRC transpose type for reads.

 - static void [CRC_HAL_SetReadTranspose](#) (CRC_Type *base, [crc_transpose_t](#) transp)

Sets the CRC transpose type for reads.

 - static bool [CRC_HAL_GetXorMode](#) (CRC_Type *base)

Gets the CRC XOR mode.

 - static void [CRC_HAL_SetXorMode](#) (CRC_Type *base, bool enable)

Sets the CRC XOR mode.

 - static [crc_prot_width_t](#) [CRC_HAL_GetProtocolWidth](#) (CRC_Type *base)

Gets the CRC protocol width.

 - static void [CRC_HAL_SetProtocolWidth](#) (CRC_Type *base, [crc_prot_width_t](#) width)

Sets the CRC protocol width.

 - uint32_t [CRC_HAL_GetCrc32](#) (CRC_Type *base, uint32_t data, bool newSeed, uint32_t seed)

CRC_HAL_GetCrc32.

 - uint32_t [CRC_HAL_GetCrc16](#) (CRC_Type *base, uint16_t data, bool newSeed, uint32_t seed)

CRC_HAL_GetCrc16.

 - uint32_t [CRC_HAL_GetCrc8](#) (CRC_Type *base, uint8_t data, bool newSeed, uint32_t seed)

CRC_HAL_GetCrc8.

CRC HAL driver

- uint32_t [CRC_HAL_GetCrcResult](#) (CRC_Type *base)
CRC_HAL_GetCrcResult.

11.2.2 Enumeration Type Documentation

11.2.2.1 enum crc_status_t

CRC status return codes.

Enumerator

- kStatus_CRC_Success* Success.
- kStatus_CRC_InvalidArgument* Invalid argument existed.
- kStatus_CRC_Failed* Execution failed.

11.2.2.2 enum crc_transpose_t

Enumerator

- kCrcNoTranspose* No transposition.
- kCrcTransposeBits* Bits in bytes are transposed; bytes are not transposed.
- kCrcTransposeBoth* Both bits in bytes and bytes are transposed.
- kCrcTransposeBytes* Only bytes are transposed; no bits in a byte are transposed.

11.2.2.3 enum crc_prot_width_t

Enumerator

- kCrc16Bits* 16-bit CRC protocol.
- kCrc32Bits* 32-bit CRC protocol.

11.2.3 Function Documentation

11.2.3.1 void CRC_HAL_Init (CRC_Type * base)

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

11.2.3.2 `static uint32_t CRC_HAL_GetDataReg (CRC_Type * base) [inline], [static]`

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 32-bit value.

11.2.3.3 `static uint16_t CRC_HAL_GetDataHReg (CRC_Type * base) [inline], [static]`

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 16-bit value.

11.2.3.4 `static uint16_t CRC_HAL_GetDataLReg (CRC_Type * base) [inline], [static]`

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 16-bit value.

11.2.3.5 `static void CRC_HAL_SetDataReg (CRC_Type * base, uint32_t value) [inline], [static]`

CRC HAL driver

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 32-bit value. |

**11.2.3.6 static void CRC_HAL_SetDataHReg (CRC_Type * *base*, uint16_t *value*)
[inline], [static]**

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 16-bit value. |

**11.2.3.7 static void CRC_HAL_SetDataLReg (CRC_Type * *base*, uint16_t *value*)
[inline], [static]**

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 16-bit value. |

**11.2.3.8 static void CRC_HAL_SetDataHLReg (CRC_Type * *base*, uint8_t *value*)
[inline], [static]**

Parameters

| | |
|--------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 8-bit value. |

**11.2.3.9 static void CRC_HAL_SetDataHUReg (CRC_Type * *base*, uint8_t *value*)
[inline], [static]**

Parameters

| | |
|--------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 8-bit value. |

11.2.3.10 static void CRC_HAL_SetDataLLReg (CRC_Type * *base*, uint8_t *value*) [inline], [static]

Parameters

| | |
|--------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 8-bit value. |

11.2.3.11 static void CRC_HAL_SetDataLUReg (CRC_Type * *base*, uint8_t *value*) [inline], [static]

Parameters

| | |
|--------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | New data for CRC computation. This parameter is a 8-bit value. |

11.2.3.12 static uint32_t CRC_HAL_GetPolyReg (CRC_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 32-bit value.

11.2.3.13 static uint16_t CRC_HAL_GetPolyHReg (CRC_Type * *base*) [inline], [static]

CRC HAL driver

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 16-bit value.

11.2.3.14 `static uint16_t CRC_HAL_GetPolyLReg (CRC_Type * base) [inline], [static]`

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 16-bit value.

11.2.3.15 `static void CRC_HAL_SetPolyReg (CRC_Type * base, uint32_t value) [inline], [static]`

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | Polynomial value. This parameter is a 32-bit value. |

11.2.3.16 `static void CRC_HAL_SetPolyHReg (CRC_Type * base, uint16_t value) [inline], [static]`

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | Polynomial value. This parameter is a 16-bit value. |

11.2.3.17 static void CRC_HAL_SetPolyLReg (CRC_Type * *base*, uint16_t *value*) [inline], [static]

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | Polynomial value. This parameter is a 16-bit value. |

11.2.3.18 static uint32_t CRC_HAL_GetCtrlReg (CRC_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

Returns a 32-bit value.

11.2.3.19 static void CRC_HAL_SetCtrlReg (CRC_Type * *base*, uint32_t *value*) [inline], [static]

Parameters

| | |
|--------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>value</i> | Control register value. This parameter is a 32-bit value. |

11.2.3.20 static bool CRC_HAL_GetSeedOrDataMode (CRC_Type * *base*) [inline], [static]

Parameters

CRC HAL driver

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

CRC seed mode -true: Seed mode is enabled -false: Data mode is enabled

11.2.3.21 static void CRC_HAL_SetSeedOrDataMode (CRC_Type * *base*, bool *enable*)
[inline], [static]

Parameters

| | |
|---------------|---|
| <i>base</i> | The CRC peripheral base address. |
| <i>enable</i> | Enable or disable seed mode. -true: use CRC data register for seed values -false: use CRC data register for data values |

11.2.3.22 static crc_transpose_t CRC_HAL_GetWriteTranspose (CRC_Type * *base*)
[inline], [static]

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

CRC input transpose type for writes.

11.2.3.23 static void CRC_HAL_SetWriteTranspose (CRC_Type * *base*, crc_transpose_t *transp*)
[inline], [static]

Parameters

| | |
|---------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
| <i>transp</i> | The CRC input transpose type. |

**11.2.3.24 static crc_transpose_t CRC_HAL_GetReadTranspose (CRC_Type * *base*)
[inline], [static]**

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

CRC output transpose type.

**11.2.3.25 static void CRC_HAL_SetReadTranspose (CRC_Type * *base*, crc_transpose_t
transp) [inline], [static]**

Parameters

| | |
|---------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
| <i>transp</i> | The CRC output transpose type. |

**11.2.3.26 static bool CRC_HAL_GetXorMode (CRC_Type * *base*) [inline],
[static]**

Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. XOR mode enables "on the fly" complementing of read data.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

CRC XOR mode -true: XOR mode is enabled -false: XOR mode is disabled

**11.2.3.27 static void CRC_HAL_SetXorMode (CRC_Type * *base*, bool *enable*)
[inline], [static]**

Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. XOR mode enables "on the fly" complementing of read data.

CRC HAL driver

Parameters

| | |
|---------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
| <i>enable</i> | Enable or disable XOR mode. |

11.2.3.28 static crc_prot_width_t CRC_HAL_GetProtocolWidth (CRC_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

CRC protocol width -kCrc16Bits: 16-bit CRC protocol -kCrc32Bits: 32-bit CRC protocol

11.2.3.29 static void CRC_HAL_SetProtocolWidth (CRC_Type * *base*, crc_prot_width_t *width*) [inline], [static]

Parameters

| | |
|--------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>width</i> | The CRC protocol width -kCrc16Bits: 16-bit CRC protocol -kCrc32Bits: 32-bit CRC protocol |

11.2.3.30 uint32_t CRC_HAL_GetCrc32 (CRC_Type * *base*, uint32_t *data*, bool *newSeed*, uint32_t *seed*)

This method appends 32-bit data to the current CRC calculation and returns new result. If the newSeed is true, seed set and result are calculated from the seed new value (new CRC calculation).

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
| <i>data</i> | input data for CRC calculation |

| | |
|----------------|--|
| <i>newSeed</i> | Sets new CRC calculation. <ul style="list-style-type: none"> • true: New seed set and used for new calculation. • false: seed argument ignored, continues old calculation. |
| <i>seed</i> | New seed if newSeed is true, else ignored |

Returns

new CRC result.

11.2.3.31 `uint32_t CRC_HAL_GetCrc16 (CRC_Type * base, uint16_t data, bool newSeed, uint32_t seed)`

This method appends the 16-bit data to the current CRC calculation and returns a new result. If the newSeed is true, seed set and result are calculated from the seed new value (new CRC calculation).

Parameters

| | |
|----------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>data</i> | input data for CRC calculation |
| <i>newSeed</i> | Sets new CRC calculation. <ul style="list-style-type: none"> • true: New seed set and used for new calculation. • false: seed argument ignored, continues old calculation. |
| <i>seed</i> | New seed if newSeed is true, else ignored |

Returns

new CRC result.

11.2.3.32 `uint32_t CRC_HAL_GetCrc8 (CRC_Type * base, uint8_t data, bool newSeed, uint32_t seed)`

This method appends the 8-bit data to the current CRC calculation and returns the new result. If the newSeed is true, seed set and result are calculated from the seed new value (new CRC calculation).

CRC HAL driver

Parameters

| | |
|----------------|--|
| <i>base</i> | The CRC peripheral base address. |
| <i>data</i> | input data for CRC calculation |
| <i>newSeed</i> | Sets new CRC calculation. <ul style="list-style-type: none"> • true: New seed set and used for new calculation. • false: seed argument ignored, continues old calculation. |
| <i>seed</i> | New seed if newSeed is true, else ignored |

Returns

new CRC result.

11.2.3.33 uint32_t CRC_HAL_GetCrcResult (CRC_Type * *base*)

This method returns the current result of the CRC calculation. The result is the ReadTranspose dependent.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The CRC peripheral base address. |
|-------------|----------------------------------|

Returns

result of CRC calculation.

11.3 CRC driver

11.3.1 Overview

This section describes the programming interface of the CRC driver.

11.3.2 CRC Driver Initialization

To initialize the CRC module, call [CRC_DRV_Init\(\)](#) function and pass the user configuration data structure to it.

11.3.3 CRC Driver Operation

The [CRC_DRV_Configure\(\)](#) function is used to write the user configuration to the CRC hardware module before starting operation by calling the [CRC_DRV_GetCrcBlock\(\)](#) function.

Data Structures

- struct [crc_user_config_t](#)
Defines a structure to initialize the CRC module. [More...](#)

Functions

- [crc_status_t](#) [CRC_DRV_Init](#) (uint32_t instance, const [crc_user_config_t](#) *userConfigPtr)
Initializes the CRC module.
- void [CRC_DRV_Deinit](#) (uint32_t instance)
CRC_DRV_Deinit.
- uint32_t [CRC_DRV_GetCrcBlock](#) (uint32_t instance, uint8_t *data, uint32_t dataLen)
CRC_DRV_GetCrcBlock.
- [crc_status_t](#) [CRC_DRV_Configure](#) (uint32_t instance, const [crc_user_config_t](#) *userConfigPtr)
CRC_DRV_Configure.

Variables

- CRC_Type *const [g_crcBase](#) [CRC_INSTANCE_COUNT]
Table of base addresses for the CRC instances.

CRC driver

11.3.4 Data Structure Documentation

11.3.4.1 struct crc_user_config_t

This structure holds the configuration for the CRC.

Data Fields

- [crc_prot_width_t](#) `crcWidth`
Selects 16 or 32-bit CRC protocol.
- [uint32_t](#) `seed`
Value of the seed (initial) CRC value.
- [uint32_t](#) `polynomial`
Value of the polynomial for the CRC calculation
Example polynomial: $0x1021 = 1_0000_0010_0001 = x^{12} + x^5 + 1$.
- [crc_transpose_t](#) `writeTranspose`
Defines transpose configuration of the data written to the CRC data register.
- [crc_transpose_t](#) `readTranspose`
Defines transpose configuration of the value read from the CRC data register.
- [bool](#) `complementRead`
Enables complement read of CRC data register.

11.3.5 Function Documentation

11.3.5.1 `crc_status_t CRC_DRV_Init (uint32_t instance, const crc_user_config_t * userConfigPtr)`

This API should be called with the initial configuration before any other operations.

Parameters

| | |
|----------------------|---|
| <i>instance</i> | CRC instance ID. |
| <i>userConfigPtr</i> | Pointer to structure of initialization, see to "crc_user_config_t". |

Returns

Execution status.

11.3.5.2 `void CRC_DRV_Deinit (uint32_t instance)`

Shuts down the CRC instance.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | CRC instance ID. |
|-----------------|------------------|

Returns

Execution status.

11.3.5.3 `uint32_t CRC_DRV_GetCrcBlock (uint32_t instance, uint8_t * data, uint32_t dataLen)`

This function appends a block of bytes to the current CRC calculation and returns a new result.

Parameters

| | |
|-----------------|----------------------------------|
| <i>instance</i> | CRC instance ID. |
| <i>data</i> | data for current CRC calculation |
| <i>dataLen</i> | length of data to be calculated |

Returns

Execution status.

11.3.5.4 `crc_status_t CRC_DRV_Configure (uint32_t instance, const crc_user_config_t * userConfigPtr)`

This function configures the CRC module from a user configuration structure.

Parameters

| | |
|----------------------|---|
| <i>instance</i> | CRC instance ID. |
| <i>userConfigPtr</i> | Pointer to structure of initialization, see to "crc_user_config_t". |

Returns

Execution status.

11.3.6 Variable Documentation

11.3.6.1 `CRC_Type* const g_crcBase[CRC_INSTANCE_COUNT]`

Chapter 12

Clock Manager (Clock)

The Kinetis SDK Clock Manager provides a set of API/services to configure the clock-related IPs, such as MCG, SIM, and so on.

12.1 Overview

Modules

- [K02F12810](#)

Typedefs

- typedef
[clock_manager_error_code_t](#)(* [clock_manager_callback_t](#))(clock_notify_struct_t *notify, void *callbackData)
Type of the clock callback functions.

Enumerations

- enum [clock_systick_src_t](#) {
 [kClockSystickSrcExtRef](#) = 0U,
 [kClockSystickSrcCore](#) = 1U }
Systick clock source selection.
- enum [clock_names_t](#) {
 [kCoreClock](#),
 [kSystemClock](#),
 [kPlatformClock](#),
 [kBusClock](#),
 [kFlexBusClock](#),
 [kFlashClock](#),
 [kFastPeripheralClock](#),
 [kSystickClock](#),
 [kOsc32kClock](#),
 [kOsc0ErClock](#),
 [kOsc1ErClock](#),
 [kOsc0ErClockUndiv](#),
 [kIrc48mClock](#),
 [kRtcoutClock](#),
 [kMcgFfClock](#),
 [kMcgFllClock](#),
 [kMcgPll0Clock](#),
 [kMcgPll1Clock](#),
 [kMcgExtPllClock](#),
 [kMcgOutClock](#),
 [kMcgIrClock](#),
 [kLpoClock](#) }
A clock name used to get the clock frequency.

- enum `clock_manager_error_code_t` {
`kClockManagerSuccess`,
`kClockManagerError`,
`kClockManagerNoSuchClockName`,
`kClockManagerInvalidParam`,
`kClockManagerErrorOutOfRange`,
`kClockManagerErrorNotificationBefore`,
`kClockManagerErrorNotificationAfter`,
`kClockManagerErrorUnknown` }
Error code definition for the clock manager APIs.
- enum `clock_manager_notify_t` {
`kClockManagerNotifyRecover` = 0x00U,
`kClockManagerNotifyBefore` = 0x01U,
`kClockManagerNotifyAfter` = 0x02U }
The clock notification type.
- enum `clock_manager_callback_type_t` {
`kClockManagerCallbackBefore` = 0x01U,
`kClockManagerCallbackAfter` = 0x02U,
`kClockManagerCallbackBeforeAfter` = 0x03U }
The callback type, which indicates the kinds of notification this callback handles.
- enum `clock_manager_policy_t` {
`kClockManagerPolicyAgreement`,
`kClockManagerPolicyForcible` }
Clock transition policy.

Functions

- `clock_manager_error_code_t` `CLOCK_SYS_GetFreq` (`clock_names_t` clockName, `uint32_t` *frequency)
Gets the clock frequency for a specific clock name.
- `uint32_t` `CLOCK_SYS_GetCoreClockFreq` (void)
Gets the core clock frequency.
- `uint32_t` `CLOCK_SYS_GetSystemClockFreq` (void)
Gets the system clock frequency.
- `uint32_t` `CLOCK_SYS_GetBusClockFreq` (void)
Gets the bus clock frequency.
- `uint32_t` `CLOCK_SYS_GetFlashClockFreq` (void)
Gets the flash clock frequency.
- static `uint32_t` `CLOCK_SYS_GetLpoClockFreq` (void)
Gets the LPO clock frequency.
- static void `CLOCK_SYS_SetSystickSrc` (`clock_systick_src_t` src)
Sets the Systick clock source SYST_CSR[CLKSOURCE].
- static `uint32_t` `CLOCK_SYS_GetSystickFreq` (void)
Gets the Systick clock frequency.
- static void `CLOCK_SYS_SetOutDiv1` (`uint8_t` outdiv1)
Sets the clock out divider1 setting(OUTDIV1).
- static `uint8_t` `CLOCK_SYS_GetOutDiv1` (void)
Gets the clock out divider1 setting(OUTDIV1).
- static void `CLOCK_SYS_SetOutDiv2` (`uint8_t` outdiv2)

Overview

- Sets the clock out divider2 setting(OUTDIV2).*
- static uint8_t **CLOCK_SYS_GetOutDiv2** (void)
 - Gets the clock out divider2 setting(OUTDIV2).*
- static void **CLOCK_SYS_SetOutDiv4** (uint8_t outdiv4)
 - Sets the clock out divider4 setting(OUTDIV4).*
- static uint8_t **CLOCK_SYS_GetOutDiv4** (void)
 - Gets the clock out divider4 setting(OUTDIV4).*
- static void **CLOCK_SYS_SetOutDiv** (uint8_t outdiv1, uint8_t outdiv2, uint8_t outdiv3, uint8_t outdiv4)
 - Sets the clock out dividers setting.*
- static void **CLOCK_SYS_GetOutDiv** (uint8_t *outdiv1, uint8_t *outdiv2, uint8_t *outdiv3, uint8_t *outdiv4)
 - Gets the clock out dividers setting.*
- uint32_t **CLOCK_SYS_GetPllfllClockFreq** (void)
 - Get the MCGPLLCLK/MCGFLLCLK/IRC48MCLK clock frequency.*
- static void **CLOCK_SYS_SetPllfllSel** (clock_pllfl_sel_t setting)
 - Set PLL/FLL clock selection.*
- static clock_pllfl_sel_t **CLOCK_SYS_GetPllfllSel** (void)
 - Get PLL/FLL clock selection.*
- static uint32_t **CLOCK_SYS_GetFixedFreqClockFreq** (void)
 - Gets the MCGFFCLK clock frequency.*
- static uint32_t **CLOCK_SYS_GetInternalRefClockFreq** (void)
 - Get internal reference clock frequency.*
- uint32_t **CLOCK_SYS_GetExternalRefClock32kFreq** (void)
 - Gets the external reference 32k clock frequency.*
- static void **CLOCK_SYS_SetExternalRefClock32kSrc** (clock_er32k_src_t src)
 - Set the clock selection of ERCLK32K.*
- static clock_er32k_src_t **CLOCK_SYS_GetExternalRefClock32kSrc** (void)
 - Get the clock selection of ERCLK32K.*
- uint32_t **CLOCK_SYS_GetOsc0ExternalRefClockFreq** (void)
 - Gets the OSC0ERCLK frequency.*
- uint32_t **CLOCK_SYS_GetOsc0ExternalRefClockUndivFreq** (void)
 - Gets the OSC0ERCLK_UNDIV frequency.*
- uint32_t **CLOCK_SYS_GetWdogFreq** (uint32_t instance, clock_wdog_src_t wdogSrc)
 - Gets the watch dog clock frequency.*
- static clock_trace_src_t **CLOCK_SYS_GetTraceSrc** (uint32_t instance)
 - Gets the debug trace clock source.*
- static void **CLOCK_SYS_SetTraceSrc** (uint32_t instance, clock_trace_src_t src)
 - Sets the debug trace clock source.*
- uint32_t **CLOCK_SYS_GetTraceFreq** (uint32_t instance)
 - Gets the debug trace clock frequency.*
- uint32_t **CLOCK_SYS_GetPortFilterFreq** (uint32_t instance, clock_port_filter_src_t src)
 - Gets PORTx digital input filter clock frequency.*
- uint32_t **CLOCK_SYS_GetLptmrFreq** (uint32_t instance, clock_lptmr_src_t lptmrSrc)
 - Gets LPTMRx pre-scaler/glitch filter clock frequency.*
- static uint32_t **CLOCK_SYS_GetEwmFreq** (uint32_t instance)
 - Gets the clock frequency for EWM module.*
- static uint32_t **CLOCK_SYS_GetFtfFreq** (uint32_t instance)
 - Gets the clock frequency for FTF module.*
- static uint32_t **CLOCK_SYS_GetCrcFreq** (uint32_t instance)
 - Gets the clock frequency for CRC module.*

- static uint32_t [CLOCK_SYS_GetCmpFreq](#) (uint32_t instance)
Gets the clock frequency for CMP module.
- static uint32_t [CLOCK_SYS_GetVrefFreq](#) (uint32_t instance)
Gets the clock frequency for VREF module.
- static uint32_t [CLOCK_SYS_GetPdbFreq](#) (uint32_t instance)
Gets the clock frequency for PDB module.
- static uint32_t [CLOCK_SYS_GetPitFreq](#) (uint32_t instance)
Gets the clock frequency for PIT module.
- static uint32_t [CLOCK_SYS_GetSpiFreq](#) (uint32_t instance)
Gets the clock frequency for SPI module.
- static uint32_t [CLOCK_SYS_GetI2cFreq](#) (uint32_t instance)
Gets the clock frequency for I2C module.
- static uint32_t [CLOCK_SYS_GetAdcAltFreq](#) (uint32_t instance)
Gets ADC alternate clock frequency.
- static uint32_t [CLOCK_SYS_GetAdcAlt2Freq](#) (uint32_t instance)
Gets ADC alternate 2 clock frequency.
- static uint32_t [CLOCK_SYS_GetFtmFixedFreq](#) (uint32_t instance)
Gets FTM fixed frequency clock frequency.
- static uint32_t [CLOCK_SYS_GetFtmSystemClockFreq](#) (uint32_t instance)
Gets FTM's system clock frequency.
- uint32_t [CLOCK_SYS_GetFtmExternalFreq](#) (uint32_t instance)
Gets FTM external clock frequency.
- static [sim_ftm_clk_sel_t](#) [CLOCK_SYS_GetFtmExternalSrc](#) (uint32_t instance)
Gets FTM external clock source.
- static void [CLOCK_SYS_SetFtmExternalSrc](#) (uint32_t instance, [sim_ftm_clk_sel_t](#) ftmSrc)
Sets FTM external clock source.
- uint32_t [CLOCK_SYS_GetUartFreq](#) (uint32_t instance)
Gets the clock frequency for UART module.
- static uint32_t [CLOCK_SYS_GetGpioFreq](#) (uint32_t instance)
Gets the clock frequency for GPIO module.
- static void [CLOCK_SYS_EnableDmaClock](#) (uint32_t instance)
Enable the clock for DMA module.
- static void [CLOCK_SYS_DisableDmaClock](#) (uint32_t instance)
Disable the clock for DMA module.
- static bool [CLOCK_SYS_GetDmaGateCmd](#) (uint32_t instance)
Get the the clock gate state for DMA module.
- static void [CLOCK_SYS_EnableDmamuxClock](#) (uint32_t instance)
Enable the clock for DMAMUX module.
- static void [CLOCK_SYS_DisableDmamuxClock](#) (uint32_t instance)
Disable the clock for DMAMUX module.
- static bool [CLOCK_SYS_GetDmamuxGateCmd](#) (uint32_t instance)
Get the the clock gate state for DMAMUX module.
- void [CLOCK_SYS_EnablePortClock](#) (uint32_t instance)
Enable the clock for PORT module.
- void [CLOCK_SYS_DisablePortClock](#) (uint32_t instance)
Disable the clock for PORT module.
- bool [CLOCK_SYS_GetPortGateCmd](#) (uint32_t instance)
Get the the clock gate state for PORT module.
- static void [CLOCK_SYS_EnableEwmClock](#) (uint32_t instance)
Enable the clock for EWM module.
- static void [CLOCK_SYS_DisableEwmClock](#) (uint32_t instance)

Overview

- Disable the clock for EWM module.*

 - static bool [CLOCK_SYS_GetEwmGateCmd](#) (uint32_t instance)
Get the the clock gate state for EWM module.
 - static void [CLOCK_SYS_EnableFtfClock](#) (uint32_t instance)
Enable the clock for FTF module.
 - static void [CLOCK_SYS_DisableFtfClock](#) (uint32_t instance)
Disable the clock for FTF module.
 - static bool [CLOCK_SYS_GetFtfGateCmd](#) (uint32_t instance)
Get the the clock gate state for FTF module.
 - static void [CLOCK_SYS_EnableCrcClock](#) (uint32_t instance)
Enable the clock for CRC module.
 - static void [CLOCK_SYS_DisableCrcClock](#) (uint32_t instance)
Disable the clock for CRC module.
 - static bool [CLOCK_SYS_GetCrcGateCmd](#) (uint32_t instance)
Get the the clock gate state for CRC module.
 - void [CLOCK_SYS_EnableAdcClock](#) (uint32_t instance)
Enable the clock for ADC module.
 - void [CLOCK_SYS_DisableAdcClock](#) (uint32_t instance)
Disable the clock for ADC module.
 - bool [CLOCK_SYS_GetAdcGateCmd](#) (uint32_t instance)
Get the the clock gate state for ADC module.
 - static void [CLOCK_SYS_EnableCmpClock](#) (uint32_t instance)
Enable the clock for CMP module.
 - static void [CLOCK_SYS_DisableCmpClock](#) (uint32_t instance)
Disable the clock for CMP module.
 - static bool [CLOCK_SYS_GetCmpGateCmd](#) (uint32_t instance)
Get the the clock gate state for CMP module.
 - void [CLOCK_SYS_EnableDacClock](#) (uint32_t instance)
Enable the clock for DAC module.
 - void [CLOCK_SYS_DisableDacClock](#) (uint32_t instance)
Disable the clock for DAC module.
 - bool [CLOCK_SYS_GetDacGateCmd](#) (uint32_t instance)
Get the the clock gate state for DAC module.
 - static void [CLOCK_SYS_EnableVrefClock](#) (uint32_t instance)
Enable the clock for VREF module.
 - static void [CLOCK_SYS_DisableVrefClock](#) (uint32_t instance)
Disable the clock for VREF module.
 - static bool [CLOCK_SYS_GetVrefGateCmd](#) (uint32_t instance)
Get the the clock gate state for VREF module.
 - static void [CLOCK_SYS_EnablePdbClock](#) (uint32_t instance)
Enable the clock for PDB module.
 - static void [CLOCK_SYS_DisablePdbClock](#) (uint32_t instance)
Disable the clock for PDB module.
 - static bool [CLOCK_SYS_GetPdbGateCmd](#) (uint32_t instance)
Get the the clock gate state for PDB module.
 - void [CLOCK_SYS_EnableFtmClock](#) (uint32_t instance)
Enable the clock for FTM module.
 - void [CLOCK_SYS_DisableFtmClock](#) (uint32_t instance)
Disable the clock for FTM module.
 - bool [CLOCK_SYS_GetFtmGateCmd](#) (uint32_t instance)
Get the the clock gate state for FTM module.

- static void [CLOCK_SYS_EnablePitClock](#) (uint32_t instance)
Enable the clock for PIT module.
- static void [CLOCK_SYS_DisablePitClock](#) (uint32_t instance)
Disable the clock for PIT module.
- static bool [CLOCK_SYS_GetPitGateCmd](#) (uint32_t instance)
Get the the clock gate state for PIT module.
- static void [CLOCK_SYS_EnableLptmrClock](#) (uint32_t instance)
Enable the clock for LPTIMER module.
- static void [CLOCK_SYS_DisableLptmrClock](#) (uint32_t instance)
Disable the clock for LPTIMER module.
- static bool [CLOCK_SYS_GetLptmrGateCmd](#) (uint32_t instance)
Get the the clock gate state for LPTIMER module.
- void [CLOCK_SYS_EnableSpiClock](#) (uint32_t instance)
Enable the clock for SPI module.
- void [CLOCK_SYS_DisableSpiClock](#) (uint32_t instance)
Disable the clock for SPI module.
- bool [CLOCK_SYS_GetSpiGateCmd](#) (uint32_t instance)
Get the the clock gate state for SPI module.
- void [CLOCK_SYS_EnableI2cClock](#) (uint32_t instance)
Enable the clock for I2C module.
- void [CLOCK_SYS_DisableI2cClock](#) (uint32_t instance)
Disable the clock for I2C module.
- bool [CLOCK_SYS_GetI2cGateCmd](#) (uint32_t instance)
Get the the clock gate state for I2C module.
- void [CLOCK_SYS_EnableUartClock](#) (uint32_t instance)
Enable the clock for UART module.
- void [CLOCK_SYS_DisableUartClock](#) (uint32_t instance)
Disable the clock for UART module.
- bool [CLOCK_SYS_GetUartGateCmd](#) (uint32_t instance)
Get the the clock gate state for UART module.
- static void [CLOCK_SYS_SetFtmExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the FTM external clock frequency(FTM_CLKx).
- static void [CLOCK_SYS_SetOutDiv3](#) (uint8_t outdiv3)
Sets the clock out divider3 setting(OUTDIV3).
- static uint8_t [CLOCK_SYS_GetOutDiv3](#) (void)
Gets the clock out divider3 setting(OUTDIV3).
- uint32_t [CLOCK_SYS_GetFlexbusFreq](#) (void)
Get flexbus clock frequency.
- static uint32_t [CLOCK_SYS_GetRtcFreq](#) (uint32_t instance)
Gets RTC input clock frequency.
- uint32_t [CLOCK_SYS_GetRtcOutFreq](#) (void)
Gets RTC_CLKOUT frequency.
- static clock_rtcout_src_t [CLOCK_SYS_GetRtcOutSrc](#) (void)
Gets RTC_CLKOUT source.
- static void [CLOCK_SYS_SetRtcOutSrc](#) (clock_rtcout_src_t src)
Gets RTC_CLKOUT source.
- static clock_rmii_src_t [CLOCK_SYS_GetEnetRmiiSrc](#) (uint32_t instance)
Gets ethernet RMII clock source.
- static void [CLOCK_SYS_SetEnetRmiiSrc](#) (uint32_t instance, clock_rmii_src_t rmiiSrc)
Sets ethernet RMII clock source.
- uint32_t [CLOCK_SYS_GetEnetRmiiFreq](#) (uint32_t instance)

Overview

- *Gets ethernet RMII clock frequency.*
- uint32_t [CLOCK_SYS_GetFlexcanFreq](#) (uint32_t instance, [clock_flexcan_src_t](#) flexcanSrc)
- *Gets FLEXCAN clock frequency.*
- static void [CLOCK_SYS_SetEnetTimeStampSrc](#) (uint32_t instance, [clock_time_src_t](#) timeSrc)
- *Set the ethernet timestamp clock source selection.*
- static [clock_time_src_t](#) [CLOCK_SYS_GetEnetTimeStampSrc](#) (uint32_t instance)
- *Get the ethernet timestamp clock source selection.*
- uint32_t [CLOCK_SYS_GetEnetTimeStampFreq](#) (uint32_t instance)
- *Gets ethernet timestamp clock frequency.*
- static uint32_t [CLOCK_SYS_GetCmtFreq](#) (uint32_t instance)
- *Gets the clock frequency for CMT module.*
- uint32_t [CLOCK_SYS_GetSdhcFreq](#) (uint32_t instance)
- *Gets the clock frequency for SDHC.*
- static void [CLOCK_SYS_SetSdhcSrc](#) (uint32_t instance, [clock_sdhc_src_t](#) setting)
- *Set the SDHC clock source selection.*
- static [clock_sdhc_src_t](#) [CLOCK_SYS_GetSdhcSrc](#) (uint32_t instance)
- *Get the SDHC clock source selection.*
- uint32_t [CLOCK_SYS_GetSaiFreq](#) (uint32_t instance, [clock_sai_src_t](#) saiSrc)
- *Gets the clock frequency for SAI.*
- static uint32_t [CLOCK_SYS_GetUsbdcdFreq](#) (uint32_t instance)
- *Gets the clock frequency for USB DCD module.*
- static void [CLOCK_SYS_EnableMpuClock](#) (uint32_t instance)
- *Enable the clock for MPU module.*
- static void [CLOCK_SYS_DisableMpuClock](#) (uint32_t instance)
- *Disable the clock for MPU module.*
- static bool [CLOCK_SYS_GetMpuGateCmd](#) (uint32_t instance)
- *Get the the clock gate state for MPU module.*
- static void [CLOCK_SYS_EnableFlexbusClock](#) (uint32_t instance)
- *Enable the clock for FLEXBUS module.*
- static void [CLOCK_SYS_DisableFlexbusClock](#) (uint32_t instance)
- *Disable the clock for FLEXBUS module.*
- static bool [CLOCK_SYS_GetFlexbusGateCmd](#) (uint32_t instance)
- *Get the the clock gate state for FLEXBUS module.*
- static void [CLOCK_SYS_EnableRngaClock](#) (uint32_t instance)
- *Enable the clock for RNGA module.*
- static void [CLOCK_SYS_DisableRngaClock](#) (uint32_t instance)
- *Disable the clock for RNGA module.*
- static bool [CLOCK_SYS_GetRngaGateCmd](#) (uint32_t instance)
- *Get the the clock gate state for RNGA module.*
- static void [CLOCK_SYS_EnableSaiClock](#) (uint32_t instance)
- *Enable the clock for SAI module.*
- static void [CLOCK_SYS_DisableSaiClock](#) (uint32_t instance)
- *Disable the clock for SAI module.*
- static bool [CLOCK_SYS_GetSaiGateCmd](#) (uint32_t instance)
- *Get the the clock gate state for SAI module.*
- static void [CLOCK_SYS_EnableCmtClock](#) (uint32_t instance)
- *Enable the clock for CMT module.*
- static void [CLOCK_SYS_DisableCmtClock](#) (uint32_t instance)
- *Disable the clock for CMT module.*
- static bool [CLOCK_SYS_GetCmtGateCmd](#) (uint32_t instance)
- *Get the the clock gate state for CMT module.*

- static void [CLOCK_SYS_EnableRtcClock](#) (uint32_t instance)
Enable the clock for RTC module.
- static void [CLOCK_SYS_DisableRtcClock](#) (uint32_t instance)
Disable the clock for RTC module.
- static bool [CLOCK_SYS_GetRtcGateCmd](#) (uint32_t instance)
Get the the clock gate state for RTC module.
- static void [CLOCK_SYS_EnableEnetClock](#) (uint32_t instance)
Enable the clock for ENET module.
- static void [CLOCK_SYS_DisableEnetClock](#) (uint32_t instance)
Disable the clock for ENET module.
- static bool [CLOCK_SYS_GetEnetGateCmd](#) (uint32_t instance)
Get the the clock gate state for ENET module.
- void [CLOCK_SYS_EnableFlexcanClock](#) (uint32_t instance)
Enable the clock for FLEXCAN module.
- void [CLOCK_SYS_DisableFlexcanClock](#) (uint32_t instance)
Disable the clock for FLEXCAN module.
- bool [CLOCK_SYS_GetFlexcanGateCmd](#) (uint32_t instance)
Get the the clock gate state for FLEXCAN module.
- static void [CLOCK_SYS_EnableSdhcClock](#) (uint32_t instance)
Enable the clock for SDHC module.
- static void [CLOCK_SYS_DisableSdhcClock](#) (uint32_t instance)
Disable the clock for SDHC module.
- static bool [CLOCK_SYS_GetSdhcGateCmd](#) (uint32_t instance)
Get the the clock gate state for SDHC module.
- static void [CLOCK_SYS_EnableTsiClock](#) (uint32_t instance)
Enable the clock for TSI module.
- static void [CLOCK_SYS_DisableTsiClock](#) (uint32_t instance)
Disable the clock for TSI module.
- static bool [CLOCK_SYS_GetTsiGateCmd](#) (uint32_t instance)
Get the the clock gate state for TSI module.
- static void [CLOCK_SYS_EnableLlwuClock](#) (uint32_t instance)
Enable the clock for LLWU module.
- static void [CLOCK_SYS_DisableLlwuClock](#) (uint32_t instance)
Disable the clock for LLWU module.
- static bool [CLOCK_SYS_GetLlwuGateCmd](#) (uint32_t instance)
Get the the clock gate state for LLWU module.
- static void [CLOCK_SYS_SetEnetExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the ENET external clock frequency(ENET_1588_CLKIN).
- static void [CLOCK_SYS_SetSdhcExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the SDHC external clock frequency(SDHC_CLKIN).
- uint32_t [CLOCK_SYS_GetUsbfsFreq](#) (uint32_t instance)
Gets the clock frequency for USB FS OTG module.
- static void [CLOCK_SYS_SetUsbfsDiv](#) (uint32_t instance, uint8_t usbdiv, uint8_t usbfrac)
Set USB FS divider setting.
- static void [CLOCK_SYS_GetUsbfsDiv](#) (uint32_t instance, uint8_t *usbdiv, uint8_t *usbfrac)
Get USB FS divider setting.
- static void [CLOCK_SYS_EnableUsbfsClock](#) (uint32_t instance)
Enable the clock for USBFS module.
- static void [CLOCK_SYS_DisableUsbfsClock](#) (uint32_t instance)
Disable the clock for USBFS module.
- static bool [CLOCK_SYS_GetUsbfsGateCmd](#) (uint32_t instance)

Overview

- Get the the clock gate state for USB module.*

 - static void [CLOCK_SYS_EnableUsbdcdClock](#) (uint32_t instance)
Enable the clock for USBDCD module.
 - static void [CLOCK_SYS_DisableUsbdcdClock](#) (uint32_t instance)
Disable the clock for USBDCD module.
 - static bool [CLOCK_SYS_GetUsbdcdGateCmd](#) (uint32_t instance)
Get the the clock gate state for USBDCD module.
 - static [clock_usbfs_src_t](#) [CLOCK_SYS_GetUsbfsSrc](#) (uint32_t instance)
Gets the clock source for USB FS OTG module.
 - static void [CLOCK_SYS_SetUsbfsSrc](#) (uint32_t instance, [clock_usbfs_src_t](#) usbfsSrc)
Sets the clock source for USB FS OTG module.
 - void [CLOCK_SYS_Osc0Deinit](#) (void)
Deinitialize OSC0.
 - static void [CLOCK_SYS_SetUsbExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the USB external clock frequency(USB_CLKIN).
 - static [clock_lpuart_src_t](#) [CLOCK_SYS_GetLpuartSrc](#) (uint32_t instance)
Gets the clock source for LPUART module.
 - static void [CLOCK_SYS_SetLpuartSrc](#) (uint32_t instance, [clock_lpuart_src_t](#) lpuartSrc)
Sets the clock source for LPUART module.
 - uint32_t [CLOCK_SYS_GetLpuartFreq](#) (uint32_t instance)
Gets the clock frequency for LPUART module.
 - static void [CLOCK_SYS_EnableLpuartClock](#) (uint32_t instance)
Enable the clock for LPUART module.
 - static void [CLOCK_SYS_DisableLpuartClock](#) (uint32_t instance)
Disable the clock for LPUART module.
 - static bool [CLOCK_SYS_GetLpuartGateCmd](#) (uint32_t instance)
Get the the clock gate state for LPUART module.
 - uint32_t [CLOCK_SYS_GetPllFllDivClockFreq](#) (void)
Gets the PLL/FLL clock divided by the fractional divider.
 - uint32_t [CLOCK_SYS_GetTpmFreq](#) (uint32_t instance)
Gets TPM clock frequency.
 - static void [CLOCK_SYS_SetTpmSrc](#) (uint32_t instance, [clock_tpm_src_t](#) tpmSrc)
Set the TPM clock source selection.
 - static [clock_tpm_src_t](#) [CLOCK_SYS_GetTpmSrc](#) (uint32_t instance)
Get the TPM clock source selection.
 - uint32_t [CLOCK_SYS_GetTpmExternalFreq](#) (uint32_t instance)
Get the TPM external clock source frequency.
 - static void [CLOCK_SYS_SetTpmExternalSrc](#) (uint32_t instance, [sim_tpm_clk_sel_t](#) src)
Set the TPM external clock source selection.
 - static [sim_tpm_clk_sel_t](#) [CLOCK_SYS_GetTpmExternalSrc](#) (uint32_t instance)
Set the TPM external clock source selection.
 - static [clock_usbhs_slowclk_src_t](#) [CLOCK_SYS_GetUsbhsSlowClockSrc](#) (uint32_t instance)
Gets the slow clock source for USB HS/USB PHY module.
 - static void [CLOCK_SYS_SetUsbhsSlowClockSrc](#) (uint32_t instance, [clock_usbhs_slowclk_src_t](#) usbhsSrc)
Sets the clock source for USB HS/USB PHY module.
 - uint32_t [CLOCK_SYS_GetUsbhsSlowClockFreq](#) (uint32_t instance)
Gets the slow clock frequency for USB HS/USB PHY module.
 - static void [CLOCK_SYS_EnableSdramcClock](#) (uint32_t instance)
Enable the clock for SDRAMC module.
 - static void [CLOCK_SYS_DisableSdramcClock](#) (uint32_t instance)

- Disable the clock for SDRAMC module.*

 - static bool [CLOCK_SYS_GetSdramcGateCmd](#) (uint32_t instance)

Get the the clock gate state for SDRAMC module.

 - void [CLOCK_SYS_EnableTpmClock](#) (uint32_t instance)

Enable the clock for TPM module.

 - void [CLOCK_SYS_DisableTpmClock](#) (uint32_t instance)

Disable the clock for TPM module.

 - bool [CLOCK_SYS_GetTpmGateCmd](#) (uint32_t instance)

Get the the clock gate state for TPM module.

 - static void [CLOCK_SYS_EnableUsbhsClock](#) (uint32_t instance)

Enable the clock for USBHS module.

 - static void [CLOCK_SYS_DisableUsbhsClock](#) (uint32_t instance)

Disable the clock for USBHS module.

 - static bool [CLOCK_SYS_GetUsbhsGateCmd](#) (uint32_t instance)

Get the the clock gate state for USBHS module.

 - static void [CLOCK_SYS_EnableUsbphyClock](#) (uint32_t instance)

Enable the clock for USBPHY module.

 - static void [CLOCK_SYS_DisableUsbphyClock](#) (uint32_t instance)

Disable the clock for USBPHY module.

 - static bool [CLOCK_SYS_GetUsbphyGateCmd](#) (uint32_t instance)

Get the the clock gate state for USBPHY module.

 - static void [CLOCK_SYS_EnableUsbhsdcdClock](#) (uint32_t instance)

Enable the clock for USBHSDCD module.

 - static void [CLOCK_SYS_DisableUsbhsdcdClock](#) (uint32_t instance)

Disable the clock for USBHSDCD module.

 - static bool [CLOCK_SYS_GetUsbhsdcdGateCmd](#) (uint32_t instance)

Get the the clock gate state for USBHSDCD module.

 - static clock_emvsim_src_t [CLOCK_SYS_GetEmvsimSrc](#) (uint32_t instance)

Gets the clock source for EMVSIM module.

 - static void [CLOCK_SYS_SetEmvsimSrc](#) (uint32_t instance, clock_emvsim_src_t emvsimSrc)

Sets the clock source for EMVSIM module.

 - uint32_t [CLOCK_SYS_GetEmvsimFreq](#) (uint32_t instance)

Gets the clock frequency for EMVSIM module.

 - uint32_t [CLOCK_SYS_GetFlexioFreq](#) (uint32_t instance)

Gets FLEXIO clock frequency.

 - static void [CLOCK_SYS_SetFlexioSrc](#) (uint32_t instance, clock_flexio_src_t flexioSrc)

Set the FLEXIO clock source selection.

 - static clock_flexio_src_t [CLOCK_SYS_GetFlexioSrc](#) (uint32_t instance)

Get the FLEXIO clock source selection.

 - uint32_t [CLOCK_SYS_GetQspiFreq](#) (uint32_t instance, clock_qspi_src_t qspiSrc)

Gets the clock frequency for QSPI.

 - void [CLOCK_SYS_EnableEmvsimClock](#) (uint32_t instance)

Enable the clock for EMVSIM module.

 - void [CLOCK_SYS_DisableEmvsimClock](#) (uint32_t instance)

Disable the clock for EMVSIM module.

 - bool [CLOCK_SYS_GetEmvsimGateCmd](#) (uint32_t instance)

Get the the clock gate state for EMVSIM module.

 - static void [CLOCK_SYS_EnableQspiClock](#) (uint32_t instance)

Enable the clock for QSPI module.

 - static void [CLOCK_SYS_DisableQspiClock](#) (uint32_t instance)

Disable the clock for QSPI module.

Overview

- static bool [CLOCK_SYS_GetQspiGateCmd](#) (uint32_t instance)
Get the the clock gate state for QSPI module.
- static void [CLOCK_SYS_EnableFlexioClock](#) (uint32_t instance)
Enable the clock for FLEXIO module.
- static void [CLOCK_SYS_DisableFlexioClock](#) (uint32_t instance)
Disable the clock for FLEXIO module.
- static bool [CLOCK_SYS_GetFlexioGateCmd](#) (uint32_t instance)
Get the clock gate state for FLEXIO module.
- static void [CLOCK_SYS_EnableTrngClock](#) (uint32_t instance)
Enable the clock for TRNG module.
- static void [CLOCK_SYS_DisableTrngClock](#) (uint32_t instance)
Disable the clock for TRNG module.
- static bool [CLOCK_SYS_GetTrngGateCmd](#) (uint32_t instance)
Get the clock gate state for TRNG module.
- void [CLOCK_SYS_EnableLtcClock](#) (uint32_t instance)
Enable the clock for LTC module.
- void [CLOCK_SYS_DisableLtcClock](#) (uint32_t instance)
Disable the clock for LTC module.
- bool [CLOCK_SYS_GetLtcGateCmd](#) (uint32_t instance)
Get the the clock gate state for LTC module.
- uint32_t [CLOCK_SYS_GetFlcClockFreq](#) (void)
Get the MCGFLLCLK clock frequency.
- uint32_t [CLOCK_SYS_GetCopFreq](#) (uint32_t instance, [clock_cop_src_t](#) copSrc)
Gets the COP clock frequency.
- uint32_t [CLOCK_SYS_GetLpisciFreq](#) (uint32_t instance)
Gets the clock frequency for LPSCI module.
- static void [CLOCK_SYS_SetLpisciSrc](#) (uint32_t instance, [clock_lpisci_src_t](#) lpisciSrc)
Set the LPSCI clock source selection.
- static [clock_lpisci_src_t](#) [CLOCK_SYS_GetLpisciSrc](#) (uint32_t instance)
Get the LPSCI clock source selection.
- void [CLOCK_SYS_EnableLpisciClock](#) (uint32_t instance)
Enable the clock for LPSCI module.
- void [CLOCK_SYS_DisableLpisciClock](#) (uint32_t instance)
Disable the clock for LPSCI module.
- bool [CLOCK_SYS_GetLpisciGateCmd](#) (uint32_t instance)
Get the the clock gate state for LPSCI module.
- static void [CLOCK_SYS_SetTpmExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the TPM external clock frequency(TPM_CLKx).
- uint32_t [CLOCK_SYS_GetCopFreq](#) (void)
Gets COP clock frequency.
- static void [CLOCK_SYS_SetCopSrc](#) ([clock_cop_src_t](#) copSrc)
Set the COP clock source selection.
- static [clock_cop_src_t](#) [CLOCK_SYS_GetCopSrc](#) (void)
Get the COP clock source selection.
- void [CLOCK_SYS_EnableXrdcClock](#) (uint32_t instance)
Enable the clock for XRDC module.
- void [CLOCK_SYS_DisableXrdcClock](#) (uint32_t instance)
Disable the clock for XRDC module.
- bool [CLOCK_SYS_GetXrdcGateCmd](#) (uint32_t instance)
Get the the clock gate state for XRDC module.
- void [CLOCK_SYS_EnableSemaClock](#) (uint32_t instance)

- Enable the clock for SEMA module.*

 - void [CLOCK_SYS_DisableSemaClock](#) (uint32_t instance)
- Disable the clock for SEMA module.*

 - bool [CLOCK_SYS_GetSemaGateCmd](#) (uint32_t instance)
- Get the the clock gate state for SEMA module.*

 - void [CLOCK_SYS_EnableFlashClock](#) (uint32_t instance)
- Enable the clock for FLASH module.*

 - void [CLOCK_SYS_DisableFlashClock](#) (uint32_t instance)
- Disable the clock for FLASH module.*

 - bool [CLOCK_SYS_GetFlashGateCmd](#) (uint32_t instance)
- Get the the clock gate state for FLASH module.*

 - void [CLOCK_SYS_EnableMuClock](#) (uint32_t instance)
- Enable the clock for MU module.*

 - void [CLOCK_SYS_DisableMuClock](#) (uint32_t instance)
- Disable the clock for MU module.*

 - bool [CLOCK_SYS_GetMuGateCmd](#) (uint32_t instance)
- Get the the clock gate state for MU module.*

 - void [CLOCK_SYS_EnableIntmuxClock](#) (uint32_t instance)
- Enable the clock for INTMUX module.*

 - void [CLOCK_SYS_DisableIntmuxClock](#) (uint32_t instance)
- Disable the clock for INTMUX module.*

 - bool [CLOCK_SYS_GetIntmuxGateCmd](#) (uint32_t instance)
- Get the the clock gate state for INTMUX module.*

 - [clock_pit_src_t](#) [CLOCK_SYS_GetPitSrc](#) (uint32_t instance)
- Gets the clock source for PIT module.*

 - void [CLOCK_SYS_SetPitSrc](#) (uint32_t instance, [clock_pit_src_t](#) pitSrc)
- Sets the clock source for PIT module.*

 - void [CLOCK_SYS_EnableLpspiClock](#) (uint32_t instance)
- Enable the clock for LPSPi module.*

 - void [CLOCK_SYS_DisableLpspiClock](#) (uint32_t instance)
- Disable the clock for LPSPi module.*

 - bool [CLOCK_SYS_GetLpspiGateCmd](#) (uint32_t instance)
- Get the the clock gate state for LPSPi module.*

 - [clock_lpspi_src_t](#) [CLOCK_SYS_GetLpspiSrc](#) (uint32_t instance)
- Gets the clock source for LPSPi module.*

 - void [CLOCK_SYS_SetLpspiSrc](#) (uint32_t instance, [clock_lpspi_src_t](#) lpspiSrc)
- Sets the clock source for LPSPi module.*

 - uint32_t [CLOCK_SYS_GetLpspiFreq](#) (uint32_t instance)
- Gets the clock frequency for LPSPi module.*

 - void [CLOCK_SYS_EnableLpi2cClock](#) (uint32_t instance)
- Enable the clock for LPI2C module.*

 - void [CLOCK_SYS_DisableLpi2cClock](#) (uint32_t instance)
- Disable the clock for LPI2C module.*

 - bool [CLOCK_SYS_GetLpi2cGateCmd](#) (uint32_t instance)
- Get the the clock gate state for LPI2C module.*

 - [clock_lpi2c_src_t](#) [CLOCK_SYS_GetLpi2cSrc](#) (uint32_t instance)
- Gets the clock source for LPI2C module.*

 - void [CLOCK_SYS_SetLpi2cSrc](#) (uint32_t instance, [clock_lpi2c_src_t](#) lpi2cSrc)
- Sets the clock source for LPI2C module.*

 - uint32_t [CLOCK_SYS_GetLpi2cFreq](#) (uint32_t instance)
- Gets the clock frequency for LPI2C module.*

Overview

- void [CLOCK_SYS_EnableEvmsimClock](#) (uint32_t instance)
Enable the clock for EVMSIM module.
- void [CLOCK_SYS_DisableEvmsimClock](#) (uint32_t instance)
Disable the clock for EVMSIM module.
- bool [CLOCK_SYS_GetEvmsimGateCmd](#) (uint32_t instance)
Get the the clock gate state for EVMSIM module.
- [clock_evmsim_src_t](#) [CLOCK_SYS_GetEvmsimSrc](#) (uint32_t instance)
Gets the clock source for EVMSIM module.
- void [CLOCK_SYS_SetEvmsimSrc](#) (uint32_t instance, [clock_evmsim_src_t](#) evmsimSrc)
Sets the clock source for EVMSIM module.
- uint32_t [CLOCK_SYS_GetEvmsimFreq](#) (uint32_t instance)
Gets the clock frequency for EVMSIM module.
- void [CLOCK_SYS_EnableAtxClock](#) (uint32_t instance)
Enable the clock for ATX module.
- void [CLOCK_SYS_DisableAtxClock](#) (uint32_t instance)
Disable the clock for ATX module.
- bool [CLOCK_SYS_GetAtxGateCmd](#) (uint32_t instance)
Get the the clock gate state for ATX module.
- static void [CLOCK_SYS_SetOutDiv5](#) (uint8_t outdiv5)
Sets the clock out divider5 setting(OUTDIV5).
- static uint8_t [CLOCK_SYS_GetOutDiv5](#) (void)
Gets the clock out divider5 setting(OUTDIV5).
- uint32_t [CLOCK_SYS_GetOutdiv5ClockFreq](#) (void)
Gets the OUTDIV5 output clock for ADC.
- uint32_t [CLOCK_SYS_GetFastPeripheralClockFreq](#) (void)
Gets the fast peripheral clock frequency.
- uint32_t [CLOCK_SYS_GetDmaFreq](#) (uint32_t instance)
Gets the clock frequency for DMA module.
- uint32_t [CLOCK_SYS_GetDmamuxFreq](#) (uint32_t instance)
Gets the clock frequency for DMAMUX module.
- uint32_t [CLOCK_SYS_GetAdcFreq](#) (uint32_t instance)
Gets the clock frequency for ADC module.
- uint32_t [CLOCK_SYS_GetPwmFreq](#) (uint32_t instance)
Gets the clock frequency for eFlexPWM module.
- uint32_t [CLOCK_SYS_GetEncFreq](#) (uint32_t instance)
Gets the clock frequency for ENC module.
- uint32_t [CLOCK_SYS_GetXbarFreq](#) (uint32_t instance)
Gets the clock frequency for XBAR module.
- uint32_t [CLOCK_SYS_GetAoiFreq](#) (uint32_t instance)
Gets the clock frequency for AOI module.
- uint32_t [CLOCK_SYS_GetFlexcanFreq](#) (uint8_t instance, [clock_flexcan_src_t](#) flexcanSrc)
Gets FLEXCAN clock frequency.
- static void [CLOCK_SYS_EnablePwmClock](#) (uint32_t instance)
Enable the clock for eFlexPWM module.
- static void [CLOCK_SYS_DisablePwmClock](#) (uint32_t instance)
Disable the clock for eFlexPWM module.
- static bool [CLOCK_SYS_GetPwmGateCmd](#) (uint32_t instance)
Get the the clock gate state for eFlexPWM module.
- static void [CLOCK_SYS_EnableAoiClock](#) (uint32_t instance)
Enable the clock for AOI module.
- static void [CLOCK_SYS_DisableAoiClock](#) (uint32_t instance)

- Disable the clock for AOI module.*

 - static bool [CLOCK_SYS_GetAoiGateCmd](#) (uint32_t instance)

Get the the clock gate state for AOI module.
- static void [CLOCK_SYS_EnableXbarClock](#) (uint32_t instance)

Enable the clock for XBAR module.
- static void [CLOCK_SYS_DisableXbarClock](#) (uint32_t instance)

Disable the clock for XBAR module.
- static bool [CLOCK_SYS_GetXbarGateCmd](#) (uint32_t instance)

Get the the clock gate state for XBAR module.
- static void [CLOCK_SYS_EnableEncClock](#) (uint32_t instance)

Enable the clock for ENC module.
- static void [CLOCK_SYS_DisableEncClock](#) (uint32_t instance)

Disable the clock for ENC module.
- static bool [CLOCK_SYS_GetEncGateCmd](#) (uint32_t instance)

Get the the clock gate state for ENC module.

Variables

- SIM_Type *const [g_simBase](#) []
- The register base of the SIM module.*
- MCG_Type *const [g_mcgBase](#) []
- The register base of the MCG/MCG_LITE module.*
- OSC_Type *const [g_oscBase](#) []
- The register base of the OSC module.*

Dynamic clock setting

- [clock_manager_error_code_t](#) [CLOCK_SYS_Init](#) ([clock_manager_user_config_t](#) const **clock-ConfigsPtr, uint8_t configsNumber, [clock_manager_callback_user_config_t](#) **callbacksPtr, uint8_t callbacksNumber)
- Installs pre-defined clock configurations.*
- [clock_manager_error_code_t](#) [CLOCK_SYS_UpdateConfiguration](#) (uint8_t targetConfigIndex, [clock_manager_policy_t](#) policy)
- Sets the system clock configuration according to a pre-defined structure.*
- [clock_manager_error_code_t](#) [CLOCK_SYS_SetConfiguration](#) ([clock_manager_user_config_t](#) const *config)
- Sets the system clock configuration.*
- uint8_t [CLOCK_SYS_GetCurrentConfiguration](#) (void)
- Gets the current system clock configuration.*
- [clock_manager_callback_user_config_t](#) * [CLOCK_SYS_GetErrorCallback](#) (void)
- Gets the callback which returns an error in the last clock switch.*
- [mcglite_mode_error_t](#) [CLOCK_SYS_SetMcgliteMode](#) ([mcglite_config_t](#) const *targetConfig)
- Sets the MCGLite to a specific mode.*
- void [CLOCK_SYS_SetSimConfiguration](#) ([sim_config_t](#) const *simConfig)
- Sets the clock configuration in SIM module.*

OSC configuration

- [clock_manager_error_code_t](#) [CLOCK_SYS_OscInit](#) (uint32_t instance, [osc_user_config_t](#) *config)
- Initializes the OSC.*

Overview

- void `CLOCK_SYS_OscDeinit` (uint32_t instance)
Deinitializes the OSC.
- void `CLOCK_SYS_SetOscerConfiguration` (uint32_t instance, `oscer_config_t` const *config)
Configures the OSCERCLK.

RTC OSC configuration

- `clock_manager_error_code_t` `CLOCK_SYS_RtcOscInit` (uint32_t instance, `rtc_osc_user_config_t` *config)
Initializes the RTC OSC.
- void `CLOCK_SYS_RtcOscDeinit` (uint32_t instance)
Deinitializes the RTC OSC.

12.1.1 Clock Manager

Overview

The Clock Manager provides these APIs:

- Enable/Disable clock for IP modules
- Get/Set clock source for IP modules
- Get clock frequency for IP modules
- Get/Set clock dividers
- Get clock module output frequency
- OSC initialize/deinitialize
- Clock mode setting

The Clock Manager covers SIM, MCG, and OSC modules.

The Clock manager also provides the clock dynamic change service. Based on this service, applications can switch between pre-defined clock configurations. A notification framework enables drivers and applications to register callback functions to this framework. Each time that the system clock configuration is changed, drivers and applications receive a notification and change their settings.

Enable/Disable clock for IP modules

The Clock manager provides APIs in this format:

```
/* Enable IP clock.
void CLOCK_SYS_EnableIpClock(uint32_t instance);
/* Disable IP clock.
void CLOCK_SYS_DisableIpClock(uint32_t instance);
/* Get IP clock status.
bool CLOCK_SYS_GetIpGateCmd(uint32_t instance);
```

Get/Set clock source for IP modules

The Clock manager provides the clock source get/set APIs for the modules whose control registers are in SIM and MCG. These APIs are defined in this format:

```

/* Get the IP module source.
clock_ip_src_t CLOCK_SYS_GetIpSrc(uint32_t instance);

/* Set the IP module source.
void CLOCK_SYS_SetIpSrc(uint32_t instance, clock_ip_src_t ipSrc);

```

These functions are only thin wraps of HAL drivers. The parameter `clock_ip_src_t` is an enumeration defined in SIM HAL driver. See SIM HAL driver for details.

Get clock frequency for IP modules

There are two circumstances:

1. Some IP modules' clock source are chosen by SIM registers. The Clock Manager provides APIs in this format:

```
uint32_t CLOCK_SYS_GetIpFreq(uint32_t instance);
```

These functions return the clock frequency. If the clock source is not available, they return 0.

1. Some IP modules' clock source are chosen by the IP internal registers, for example SAI module. For these modules, the clock frequency APIs are defined as follows:

```
uint32_t CLOCK_SYS_GetIpFreq(clock_ip_src_t ipSrc, uint32_t instance);
```

The clock source selection is passed as a parameter. The IP driver reads its internal register and passes it to the Clock Manager to get the clock frequency.

Get/Set clock dividers

The Clock manager provides separate divider APIs for different clocks. They are defined as follows:

```

/* Get divider values.
void CLOCK_SYS_GetIpDiv(uint32_t instance, type1 *div1, type2 *div2, ...);

/* Set divider values.
void CLOCK_SYS_SetIpDiv(uint32_t instance, type1 div1, type2 div2, ...);

```

Get clock module output frequency

The Clock module outputs clocks, including MCGFFCLK, MCGIRCLK, MCGPLLFLCLK OSCERCLK, ERCLK32K, LPO, RTC_CLKOUT, core clock and so on. The Clock Manager provides separate APIs to get the frequency of these clocks. These functions are defined as follows:

```
uint32_t CLOCK_SYS_GetNameFreq();
```

These functions return the frequency in hertz. If the clock source is not available, they return 0. Passing the clock name as a parameter to the API `CLOCK_SYS_GetFreq()` function obtains the corresponding frequency.

Overview

OSC initialize/deinitialize

The Clock Manager provides functions to initialize and deinitialize the OSC. The OSC configurations are passed by the structure `osc_user_config_t`.

```
clock_manager_error_code_t CLOCK_SYS_Osc0Init(
    osc_user_config_t *config);

void CLOCK_SYS_Osc0Deinit(void);
```

Clock mode setting

The Clock generator (MCG and MCG_Lite) works in several clock modes. When switching the clock mode, the user must choose the proper path. The Clock Manager provides functions for this purpose:

```
mcg_mode_error_t CLOCK_SYS_SetMcgMode(mcg_config_t const *targetConfig);

mcglite_mode_error_t CLOCK_SYS_SetMcgliteMode(
    mcglite_config_t const *targetConfig);
```

These functions help to set MCG or MCG_Lite to target mode automatically, which means that, if the target mode cannot be reached directly, these functions are used to choose the correct path.

These functions are easy to use but have a large code size, especially for MCG. To set the MCG to some specific mode during system startup, the function `CLOCK_SYS_SetMcgMode` may not be the correct choice. In this case, the Clock Manager provides functions such as `CLOCK_SYS_BootToPee`, which are dedicate to set up the Clock during system startup. Because the target mode is specific, these functions are easier, light-weight, and have a small code size.

Dynamic clock setting

The Clock Manager dynamic clock setting is based on two components:

1. The system can switch between pre-defined Clock configurations dynamically.
Generally, there are two configurations, one for normal run mode and the other for very low power run (VLPR) mode. Some platforms, such as K22, run in HRUN power mode, which creates a need for an additional clock configuration for peak performance. See the structure `g_defaultClockConfigurations` for details.
2. Notification framework.
The Clock Manager provides a notification mechanism. IP drivers and applications should register callback functions to the notification framework. To simplify, the Clock Manager only supports the static callback registration. This means that, for applications, all callback functions are collected into a static table and passed to the Clock Manager.

The clock mode transition includes 3 steps:

- (a) Before clock mode transition, the Clock Manager sends a "BEFORE" message to the callback table. When this message is received, IP drivers should check whether any current processes can be stopped and stop them. If the processes cannot be stopped, the callback function returns an error.

The Clock Manager supports two types of transition policies, a graceful policy and a forceful policy. When the graceful policy is used, if some callbacks return an error while sending "BEFORE" message, the clock mode transition stops and the Clock Manager sends a "RECOVER"

message to all drivers that have stopped. Then, these drivers can recover the previous status and continue to work. When the forceful policy is used, drivers are stopped forcefully.

- (b) After the "BEFORE" message is processed successfully, the system clock mode changes according to the new configuration.
- (c) After the system clock mode changes, the Clock Manager sends an "AFTER" message to the callback table to notify drivers that the clock mode transition is finished.

This is an example that shows how to enable the dynamic clock setting in the application:

```

/* Callback for UART0.
uart_callback_data_t uart0CallbackData;
clock_manager_error_code_t uart0Callback(clock_notify_struct_t *notify,
                                         void* driverData);

/* Callback for ADC1.
adc_callback_data_t adc1CallbackData;
clock_manager_error_code_t adc1Callback(clock_notify_struct_t *notify,
                                         void* driverData);

/* Callback configuration for UART0.
clock_manager_callback_user_config_t uart0callbackConfig =
{
    .callback      = uart0Callback,
    .callbackType  = kClockManagerCallbackBeforeAfter,
    .callbackData  = &uart0CallbackData
};

/* Callback configuration for ADC1.
clock_manager_callback_user_config_t adc1callbackConfig =
{
    .callback      = adc1Callback,
    .callbackType  = kClockManagerCallbackBeforeAfter,
    .callbackData  = &adc1CallbackData
};

/* static clock callback table.
static clock_manager_callback_user_config clockCallbackTable [] =
{
    &uart0callbackConfig,
    &adc1callbackConfig,
};

/* Set configuration and callback table to Clock Manager.
CLOCK_SYS_Init(g_defaultClockConfigurations,
              CLOCK_CONFIG_NUM,
              clockCallbackTable,
              ARRAY_SIZE(clockCallbackTable));

```

The Clock Manager provides the default clock configuration table with the name `g_defaultClockConfigurations`. The application needs to construct the callback function table. Finally, use the function `CLOCK_SYS_Init` to set up the clock configuration and a callback table for the Clock Manager.

This is an example of a callback function:

```

clock_manager_error_code_t IPCallback(
    clock_notify_struct_t *notify,
    void *callbackData)
{
    clock_manager_error_code_t ret =
        kClockManagerSuccess;
}

```

Data Structure Documentation

```

switch (notify->notifyType)
{
    case kClockManagerNotifyBefore: // Received "BEFORE" message
        if (!ready_to_change)
        {
            ret = kClockManagerError;
        }
        if ((ret == kClockManagerSuccess) ||
            (kClockManagerPolicyForcible == notify->
policy))
        {
            // Gate IP clock and stop work.
        }
        break;
    case kClockManagerNotifyRecover: // Received "RECOVER" message
        // Recover work.
        break;
    case kClockManagerNotifyAfter: // Received "AFTER" message
        // Ungate IP clock and re-configure driver.
        break;
    default:
        ret = kClockManagerError;
        break;
}
return ret;
}

```

12.2 Data Structure Documentation

12.2.1 struct oscr_config_t

Data Fields

- bool [enable](#)
OSKERCLK enabled or not.
- bool [enableInStop](#)
OSKERCLK enabled or not in stop mode.

12.2.1.0.0.8 Field Documentation

12.2.1.0.0.8.1 bool oscr_config_t::enable

12.2.1.0.0.8.2 bool oscr_config_t::enableInStop

12.2.2 struct osc_user_config_t

Defines the configuration data structure to initialize the OSC. When porting to a new board, set the following members according to the board setting:

1. freq: The external frequency.
2. hgo/range/erefs: These members should be set based on the board setting.

Data Fields

- uint32_t [freq](#)

- *External clock frequency.*
- bool `enableCapacitor2p`
Enable 2 pF capacitor load.
- bool `enableCapacitor4p`
Enable 4 pF capacitor load.
- bool `enableCapacitor8p`
Enable 8 pF capacitor load.
- bool `enableCapacitor16p`
Enable 16 pF capacitor load.
- `osc_gain_t` `hgo`
High-gain oscillator select.
- `osc_range_t` `range`
Oscillator range setting.
- `osc_src_t` `erefs`
External reference select.
- `oscer_config_t` `oscerConfig`
Configuration for OSCERCLK.

12.2.2.0.0.9 Field Documentation

12.2.2.0.0.9.1 `uint32_t osc_user_config_t::freq`

12.2.2.0.0.9.2 `bool osc_user_config_t::enableCapacitor2p`

12.2.2.0.0.9.3 `bool osc_user_config_t::enableCapacitor4p`

12.2.2.0.0.9.4 `bool osc_user_config_t::enableCapacitor8p`

12.2.2.0.0.9.5 `bool osc_user_config_t::enableCapacitor16p`

12.2.2.0.0.9.6 `osc_gain_t osc_user_config_t::hgo`

12.2.2.0.0.9.7 `osc_range_t osc_user_config_t::range`

12.2.2.0.0.9.8 `osc_src_t osc_user_config_t::erefs`

12.2.2.0.0.9.9 `oscer_config_t osc_user_config_t::oscerConfig`

12.2.3 `struct rtc_osc_user_config_t`

Defines the configuration data structure to initialize the RTC OSC. When porting to a new board, set the following members according to the board settings:

1. `freq`: The external frequency for RTC.
2. `enableOSC`: RTC can either use its dedicate OSC or override the `OSC0` setting and use `OSC0`, or use external input clock directly. This is different for each SoC and board setting.

Data Structure Documentation

Data Fields

- `uint32_t freq`
External clock frequency.
- `bool enableCapacitor2p`
Enable 2 pF capacitor load.
- `bool enableCapacitor4p`
Enable 4 pF capacitor load.
- `bool enableCapacitor8p`
Enable 8 pF capacitor load.
- `bool enableCapacitor16p`
Enable 16 pF capacitor load.
- `bool enableOsc`
Enable OSC or use external clock directly.

12.2.3.0.0.10 Field Documentation

- 12.2.3.0.0.10.1 `uint32_t rtc_osc_user_config_t::freq`
- 12.2.3.0.0.10.2 `bool rtc_osc_user_config_t::enableCapacitor2p`
- 12.2.3.0.0.10.3 `bool rtc_osc_user_config_t::enableCapacitor4p`
- 12.2.3.0.0.10.4 `bool rtc_osc_user_config_t::enableCapacitor8p`
- 12.2.3.0.0.10.5 `bool rtc_osc_user_config_t::enableCapacitor16p`
- 12.2.3.0.0.10.6 `bool rtc_osc_user_config_t::enableOsc`

12.2.4 struct mcglite_config_t

Data Fields

- `mcglite_mode_t mcglite_mode`
MCG_LITE mode.
- `bool irclkEnable`
MCGIRCLK enable.
- `bool irclkEnableInStop`
MCGIRCLK enable in stop mode.
- `mcglite_lirc_select_t ircs`
MCG_C2[IRCS].
- `mcglite_lirc_div_t fcrdiv`
MCG_SC[FCRDIV].
- `mcglite_lirc_div_t lircDiv2`
MCG_MC[LIRC_DIV2].
- `bool hircEnableInNotHircMode`
HIRC enable when not in HIRC mode.

12.2.4.0.0.11 Field Documentation

12.2.4.0.0.11.1 `mcglite_mode_t mcglite_config_t::mcglite_mode`

12.2.4.0.0.11.2 `bool mcglite_config_t::irclkEnable`

12.2.4.0.0.11.3 `bool mcglite_config_t::irclkEnableInStop`

12.2.4.0.0.11.4 `mcglite_lirc_select_t mcglite_config_t::ircs`

12.2.4.0.0.11.5 `mcglite_lirc_div_t mcglite_config_t::fcrdiv`

12.2.4.0.0.11.6 `mcglite_lirc_div_t mcglite_config_t::lircDiv2`

12.2.4.0.0.11.7 `bool mcglite_config_t::hircEnableInNotHircMode`

12.2.5 struct `clock_manager_user_config_t`

Data Fields

- [mcglite_config_t mcgliteConfig](#)
MCGLite configuration.
- [oscer_config_t oscerConfig](#)
OSCERCLK configuration.
- [sim_config_t simConfig](#)
SIM configuration.

12.2.5.0.0.12 Field Documentation

12.2.5.0.0.12.1 `mcglite_config_t clock_manager_user_config_t::mcgliteConfig`

12.2.5.0.0.12.2 `oscer_config_t clock_manager_user_config_t::oscerConfig`

12.2.5.0.0.12.3 `sim_config_t clock_manager_user_config_t::simConfig`

12.2.6 struct `clock_notify_struct_t`

Data Fields

- `uint8_t targetClockConfigIndex`
Target clock configuration index.
- `clock_manager_policy_t policy`
Clock transition policy.
- `clock_manager_notify_t notifyType`
Clock notification type.

Data Structure Documentation

12.2.6.0.0.13 Field Documentation

12.2.6.0.0.13.1 `uint8_t clock_notify_struct_t::targetClockConfigIndex`

12.2.6.0.0.13.2 `clock_manager_policy_t clock_notify_struct_t::policy`

12.2.6.0.0.13.3 `clock_manager_notify_t clock_notify_struct_t::notifyType`

12.2.7 struct `clock_manager_callback_user_config_t`

Data Fields

- `clock_manager_callback_t callback`
Entry of callback function.
- `clock_manager_callback_type_t callbackType`
Callback type.
- `void * callbackData`
Parameter of callback function.

12.2.7.0.0.14 Field Documentation

12.2.7.0.0.14.1 `clock_manager_callback_t clock_manager_callback_user_config_t::callback`

12.2.7.0.0.14.2 `clock_manager_callback_type_t clock_manager_callback_user_config_t::callbackType`

12.2.7.0.0.14.3 `void* clock_manager_callback_user_config_t::callbackData`

12.2.8 struct `clock_manager_state_t`

Data Fields

- `clock_manager_user_config_t`
`const ** configTable`
Pointer to the clock configuration table.
- `uint8_t clockConfigNum`
Number of clock configurations.
- `uint8_t curConfigIndex`
Index of the current configuration.
- `clock_manager_callback_user_config_t ** callbackConfig`
Pointer to the callback table.
- `uint8_t callbackNum`
Number of clock callbacks.
- `uint8_t errorCallbackIndex`
Index of callback returns error.

12.2.8.0.0.15 Field Documentation**12.2.8.0.0.15.1** `clock_manager_user_config_t` const** `clock_manager_state_t::configTable`**12.2.8.0.0.15.2** `uint8_t` `clock_manager_state_t::clockConfigNum`**12.2.8.0.0.15.3** `uint8_t` `clock_manager_state_t::curConfigIndex`**12.2.8.0.0.15.4** `clock_manager_callback_user_config_t**` `clock_manager_state_t::callbackConfig`**12.2.8.0.0.15.5** `uint8_t` `clock_manager_state_t::callbackNum`**12.2.8.0.0.15.6** `uint8_t` `clock_manager_state_t::errorCallbackIndex`**12.2.9 struct sim_config_t****Data Fields**

- `clock_pllfl_sel_t` `pllFlSel`
PLL/FLL selection.
- `clock_er32k_src_t` `er32kSrc`
ERCLK32K source selection.
- `uint8_t` `flashclkmode`
CLKDIV setting.
- `uint8_t` `outdiv4`
OUTDIV setting.

12.2.9.0.0.16 Field Documentation**12.2.9.0.0.16.1** `clock_pllfl_sel_t` `sim_config_t::pllFlSel`**12.2.9.0.0.16.2** `clock_er32k_src_t` `sim_config_t::er32kSrc`**12.2.9.0.0.16.3** `uint8_t` `sim_config_t::flashclkmode`**12.2.9.0.0.16.4** `uint8_t` `sim_config_t::outdiv4`**12.2.10 struct clock_name_config_t****Data Fields**

- `bool` `useOtherRefClock`
if it uses the other ref clock
- `clock_names_t` `otherRefClockName`
other ref clock name
- `clock_divider_names_t` `dividerName`
clock divider name

Enumeration Type Documentation

12.3 Macro Definition Documentation

12.3.1 #define CPU_LPO_CLK_HZ 1000U

12.4 Typedef Documentation

12.4.1 typedef clock_manager_error_code_t(* clock_manager_callback_t)(clock_notify_struct_t *notify, void *callbackData)

12.5 Enumeration Type Documentation

12.5.1 enum clock_systick_src_t

Enumerator

- kClockSystickSrcExtRef* Use external reference clock.
- kClockSystickSrcCore* Use processor clock (Core clock).

12.5.2 enum clock_names_t

Enumerator

- kCoreClock* Core clock.
- kSystemClock* System clock.
- kPlatformClock* Platform clock.
- kBusClock* Bus clock.
- kFlexBusClock* FlexBus clock.
- kFlashClock* Flash clock.
- kFastPeripheralClock* Flash peripheral clock.
- kSystickClock* Clock for Systick.
- kOsc32kClock* ERCLK32K.
- kOsc0ErClock* OSC0ERCLK.
- kOsc1ErClock* OSC1ERCLK.
- kOsc0ErClockUndiv* OSC0ERCLK_UNDIV.
- kIrc48mClock* IRC 48M.
- kRtcoutClock* RTC_CLKOUT.
- kMcgFfClock* MCG fixed frequency clock (MCGFFCLK)
- kMcgFllClock* MCGFLLCLK.
- kMcgPll0Clock* MCGPLL0CLK.
- kMcgPll1Clock* MCGPLL1CLK.
- kMcgExtPllClock* EXT_PLLCLK.
- kMcgOutClock* MCGOUTCLK.
- kMcgIrClock* MCGIRCLK.
- kLpoClock* LPO clock.

12.5.3 enum clock_manager_error_code_t

Enumerator

kClockManagerSuccess Success.
kClockManagerError Some error occurs.
kClockManagerNoSuchClockName Invalid name.
kClockManagerInvalidParam Invalid parameter.
kClockManagerErrorOutOfRange Configuration index out of range.
kClockManagerErrorNotificationBefore Error occurs during send "BEFORE" notification.
kClockManagerErrorNotificationAfter Error occurs during send "AFTER" notification.
kClockManagerErrorUnknown Unknown error.

12.5.4 enum clock_manager_notify_t

Enumerator

kClockManagerNotifyRecover Notify IP to recover to previous work state.
kClockManagerNotifyBefore Notify IP that system will change clock setting.
kClockManagerNotifyAfter Notify IP that have changed to new clock setting.

12.5.5 enum clock_manager_callback_type_t

Enumerator

kClockManagerCallbackBefore Callback handles BEFORE notification.
kClockManagerCallbackAfter Callback handles AFTER notification.
kClockManagerCallbackBeforeAfter Callback handles BEFORE and AFTER notification.

12.5.6 enum clock_manager_policy_t

Enumerator

kClockManagerPolicyAgreement Clock transfers gracefully.
kClockManagerPolicyForcible Clock transfers forcefully.

12.6 Function Documentation

12.6.1 clock_manager_error_code_t CLOCK_SYS_GetFreq (clock_names_t *clockName*, uint32_t * *frequency*)

This function checks the current clock configurations and then calculates the clock frequency for a specific clock name defined in *clock_names_t*. The MCG must be properly configured before using this function.

Function Documentation

See the reference manual for supported clock names for different chip families. The returned value is in Hertz. If it cannot find the clock name or the name is not supported for a specific chip family, it returns an error.

Parameters

| | |
|------------------|---|
| <i>clockName</i> | Clock names defined in <code>clock_names_t</code> |
| <i>frequency</i> | Returned clock frequency value in Hertz |

Returns

status Error code defined in `clock_manager_error_code_t`

12.6.2 `uint32_t CLOCK_SYS_GetCoreClockFreq (void)`

This function gets the core clock frequency.

Returns

Current core clock frequency.

12.6.3 `uint32_t CLOCK_SYS_GetSystemClockFreq (void)`

This function gets the system clock frequency.

Returns

Current system clock frequency.

12.6.4 `uint32_t CLOCK_SYS_GetBusClockFreq (void)`

This function gets the bus clock frequency.

Returns

Current bus clock frequency.

12.6.5 uint32_t CLOCK_SYS_GetFlashClockFreq (void)

This function gets the flash clock frequency.

Returns

Current flash clock frequency.

12.6.6 static uint32_t CLOCK_SYS_GetLpoClockFreq (void) [inline], [static]

This function gets the LPO clock frequency.

Returns

Current clock frequency.

12.6.7 static void CLOCK_SYS_SetSystickSrc (clock_systick_src_t src) [inline], [static]

This function selects the clock source for Systick. The Systick clock source can be an external reference clock or a processor clock. See a reference manual for details.

Parameters

| | |
|------------|---------------------------|
| <i>src</i> | Clock source for Systick. |
|------------|---------------------------|

12.6.8 static uint32_t CLOCK_SYS_GetSystickFreq (void) [inline], [static]

This function gets the clock frequency for Systick. The Systick clock source can be an external reference clock or a processor clock. See a reference manual for details.

Returns

Clock frequency for Systick.

Function Documentation

12.6.9 `clock_manager_error_code_t` **CLOCK_SYS_Init** (`clock_manager_user_config_t` **const** ** *clockConfigsPtr*, `uint8_t` *configsNumber*, `clock_manager_callback_user_config_t` ** *callbacksPtr*, `uint8_t` *callbacksNumber*)

This function installs the pre-defined clock configuration table to the Clock Manager.

Parameters

| | |
|------------------------|--|
| <i>clockConfigsPtr</i> | Pointer to the clock configuration table. |
| <i>configsNumber</i> | Number of clock configurations in table. |
| <i>callbacksPtr</i> | Pointer to the callback configuration table. |
| <i>callbacksNumber</i> | Number of callback configurations in table. |

Returns

Error code.

12.6.10 clock_manager_error_code_t CLOCK_SYS_UpdateConfiguration (uint8_t targetConfigIndex, clock_manager_policy_t policy)

This function sets the system to the target clock configuration. Before transition, the Clock Manager sends notifications to all drivers registered to the callback table. When the graceful policy is used, if some drivers are not ready to change, the clock transition does not occur, all drivers still work in the previous configuration, and error is returned. When the forceful policy is used, all drivers should stop work and the system changes to the new clock configuration.

Parameters

| | |
|--------------------------|---|
| <i>targetConfigIndex</i> | Index of the clock configuration. |
| <i>policy</i> | Transaction policy, graceful or forceful. |

Returns

Error code.

Note

If the external clock is used in the target mode, make sure it is enabled, for example, if the external oscillator is used, set up the EREFS/HGO correctly and make sure that OSCINIT is set.

12.6.11 clock_manager_error_code_t CLOCK_SYS_SetConfiguration (clock_manager_user_config_t const * config)

This function sets the system to the target configuration. It only sets the clock module registers for clock mode change, but does not send notifications to drivers. This function is different for each SoC.

Function Documentation

Parameters

| | |
|---------------|-----------------------|
| <i>config</i> | Target configuration. |
|---------------|-----------------------|

Returns

Error code.

Note

If an external clock is used in the target mode, make sure it is enabled, for example, if the external oscillator is used, set up the EREFS/HGO correctly and make sure that OSCINIT is set.

12.6.12 `uint8_t CLOCK_SYS_GetCurrentConfiguration (void)`

Returns

Current clock configuration index.

12.6.13 `clock_manager_callback_user_config_t* CLOCK_SYS_GetErrorCallback (void)`

When the graceful policy is used, if an IP is not ready to change the clock setting, the callback returns an error and the system stays in the current configuration. Applications can use this function to check which IP callback returns an error.

Returns

Pointer to the callback which returns error.

12.6.14 `mcglite_mode_error_t CLOCK_SYS_SetMcgliteMode (mcglite_config_t const * targetConfig)`

This function sets the MCGLite to a mode according to the configuration parameter.

Parameters

| | |
|---------------------|-------------------------------------|
| <i>targetConfig</i> | Pointer to the configure structure. |
|---------------------|-------------------------------------|

Returns

Error code.

12.6.15 void CLOCK_SYS_SetSimConfiguration (sim_config_t const * *simConfig*)

Parameters

| | |
|------------------|--|
| <i>simConfig</i> | Pointer to the target SIM configuration structure. |
|------------------|--|

12.6.16 clock_manager_error_code_t CLOCK_SYS_OscInit (uint32_t *instance*, osc_user_config_t * *config*)

This function initializes the OSC according to the board configuration.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | Instance of the OSC. |
| <i>config</i> | Pointer to the OSC configuration structure. |

Returns

kClockManagerSuccess on success.

12.6.17 void CLOCK_SYS_OscDeinit (uint32_t *instance*)

This function deinitializes the OSC.

Parameters

Function Documentation

| | |
|-----------------|----------------------|
| <i>instance</i> | Instance of the OSC. |
|-----------------|----------------------|

12.6.18 void CLOCK_SYS_SetOscerConfiguration (uint32_t *instance*, oscer_config_t const * *config*)

This function configures the OSCERCLK, including whether OSCERCLK is enabled in normal mode and stop mode or not.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | Instance of the OSC. |
| <i>config</i> | Pointer to the OSCERCLK configuration structure. |

12.6.19 clock_manager_error_code_t CLOCK_SYS_RtcOscInit (uint32_t *instance*, rtc_osc_user_config_t * *config*)

This function initializes the RTC OSC according to the board configuration.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | Instance of the RTC OSC. |
| <i>config</i> | Pointer to the configuration structure. |

Returns

kClockManagerSuccess on success.

12.6.20 void CLOCK_SYS_RtcOscDeinit (uint32_t *instance*)

This function deinitializes the RTC OSC.

Parameters

| | |
|-----------------|--------------------------|
| <i>instance</i> | Instance of the RTC OSC. |
|-----------------|--------------------------|

12.6.21 static void CLOCK_SYS_SetOutDiv1 (uint8_t *outdiv1*) [inline], [static]

This function sets divide value OUTDIV1.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv1</i> | Outdivider1 setting |
|----------------|---------------------|

12.6.22 static uint8_t CLOCK_SYS_GetOutDiv1 (void) [inline], [static]

This function gets divide value OUTDIV1.

Returns

Outdivider1 setting

12.6.23 static void CLOCK_SYS_SetOutDiv2 (uint8_t *outdiv2*) [inline], [static]

This function sets divide value OUTDIV2.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv2</i> | Outdivider2 setting |
|----------------|---------------------|

12.6.24 static uint8_t CLOCK_SYS_GetOutDiv2 (void) [inline], [static]

This function gets divide value OUTDIV2.

Returns

Outdivider2 setting

12.6.25 static void CLOCK_SYS_SetOutDiv4 (uint8_t *outdiv4*) [inline], [static]

This function sets divide value OUTDIV4.

Function Documentation

Parameters

| | |
|----------------|---------------------|
| <i>outdiv4</i> | Outdivider4 setting |
|----------------|---------------------|

12.6.26 `static uint8_t CLOCK_SYS_GetOutDiv4 (void) [inline], [static]`

This function gets divide value OUTDIV4.

Returns

Outdivider4 setting

12.6.27 `static void CLOCK_SYS_SetOutDiv (uint8_t outdiv1, uint8_t outdiv2, uint8_t outdiv3, uint8_t outdiv4) [inline], [static]`

This function sets the setting for all clock out dividers at the same time.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv1</i> | Outdivider1 setting |
| <i>outdiv2</i> | Outdivider2 setting |
| <i>outdiv3</i> | Outdivider3 setting |
| <i>outdiv4</i> | Outdivider4 setting |

12.6.28 `static void CLOCK_SYS_GetOutDiv (uint8_t * outdiv1, uint8_t * outdiv2, uint8_t * outdiv3, uint8_t * outdiv4) [inline], [static]`

This function gets the setting for all clock out dividers at the same time.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv1</i> | Outdivider1 setting |
| <i>outdiv2</i> | Outdivider2 setting |

| | |
|----------------|---------------------|
| <i>outdiv3</i> | Outdivider3 setting |
| <i>outdiv4</i> | Outdivider4 setting |

12.6.29 uint32_t CLOCK_SYS_GetPIIFllClockFreq (void)

This function gets the frequency of the MCGPLLCLK/MCGFLLCLK/IRC48MCLK.

Returns

Current clock frequency.

**12.6.30 static void CLOCK_SYS_SetPIIflSel (clock_pllfl_sel_t *setting*)
[inline], [static]**

This function sets the selection of the high frequency clock for various peripheral clocking options

Parameters

| | |
|----------------|-------------------|
| <i>setting</i> | The value to set. |
|----------------|-------------------|

**12.6.31 static clock_pllfl_sel_t CLOCK_SYS_GetPIIflSel (void) [inline],
[static]**

This function gets the selection of the high frequency clock for various peripheral clocking options

Returns

Current selection.

**12.6.32 static uint32_t CLOCK_SYS_GetFixedFreqClockFreq (void) [inline],
[static]**

This function gets the MCG fixed frequency clock (MCGFFCLK) frequency.

Returns

Current clock frequency.

Function Documentation

12.6.33 `static uint32_t CLOCK_SYS_GetInternalRefClockFreq (void)`
`[inline], [static]`

This function gets the internal reference clock frequency.

Returns

Current clock frequency.

12.6.34 `uint32_t CLOCK_SYS_GetExternalRefClock32kFreq (void)`

This function gets the external reference (ERCLK32K) clock frequency.

Returns

Current frequency.

12.6.35 `static void CLOCK_SYS_SetExternalRefClock32kSrc (clock_er32k_src_t`
`src) [inline], [static]`

This function sets the clock selection of ERCLK32K.

Parameters

| | |
|------------|---------------|
| <i>src</i> | clock source. |
|------------|---------------|

12.6.36 `static clock_er32k_src_t CLOCK_SYS_GetExternalRefClock32kSrc (void`
`) [inline], [static]`

This function gets the clock selection of ERCLK32K.

Returns

Current selection.

12.6.37 `uint32_t CLOCK_SYS_GetOsc0ExternalRefClockFreq (void)`

Gets the frequency.

This function gets the OSC0 external reference frequency.

Returns

Current frequency.

12.6.38 uint32_t CLOCK_SYS_GetOsc0ExternalRefClockUndivFreq (void)

This function gets the undivided OSC0 external reference frequency.

Returns

Current frequency.

12.6.39 uint32_t CLOCK_SYS_GetWdogFreq (uint32_t *instance*, clock_wdog_src_t *wdogSrc*)

This function gets the watch dog clock frequency.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | module device instance |
| <i>wdogSrc</i> | watch dog clock source selection, WDOG_STCTRLH[CLKSRC]. |

Returns

Current frequency.

**12.6.40 static clock_trace_src_t CLOCK_SYS_GetTraceSrc (uint32_t *instance*)
[inline], [static]**

This function gets the debug trace clock source.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current source.

Function Documentation

12.6.41 `static void CLOCK_SYS_SetTraceSrc (uint32_t instance, clock_trace_src_t src) [inline], [static]`

This function sets the debug trace clock source.

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | module device instance. |
| <i>src</i> | debug trace clock source. |

12.6.42 uint32_t CLOCK_SYS_GetTraceFreq (uint32_t instance)

This function gets the debug trace clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

This function gets the debug trace clock frequency.

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | module device instance. |
|-----------------|-------------------------|

Returns

Current frequency.

12.6.43 uint32_t CLOCK_SYS_GetPortFilterFreq (uint32_t instance, clock_port_filter_src_t src)

This function gets the PORTx digital input filter clock frequency.

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | module device instance. |
| <i>src</i> | PORTx source selection. |

Function Documentation

Returns

Current frequency.

12.6.44 `uint32_t CLOCK_SYS_GetLptmrFreq (uint32_t instance, clock_lptmr_src_t lptmrSrc)`

This function gets the LPTMRx pre-scaler/glitch filter clock frequency.

Parameters

| | |
|-----------------|--------------------------------|
| <i>instance</i> | module device instance |
| <i>lptmrSrc</i> | LPTMRx clock source selection. |

Returns

Current frequency.

12.6.45 `static uint32_t CLOCK_SYS_GetEwmFreq (uint32_t instance)` `[inline], [static]`

This function gets the clock frequency for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.46 static uint32_t CLOCK_SYS_GetFtfFreq (uint32_t *instance*) [inline], [static]

(Flash Memory)

This function gets the clock frequency for FTF module. (Flash Memory)

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

(Flash Memory)

This function gets the clock frequency for FTF module. (Flash Memory)

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.47 static uint32_t CLOCK_SYS_GetCrcFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for CRC module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.48 `static uint32_t CLOCK_SYS_GetCmpFreq (uint32_t instance)` `[inline], [static]`

This function gets the clock frequency for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.49 `static uint32_t CLOCK_SYS_GetVrefFreq (uint32_t instance)` `[inline], [static]`

This function gets the clock frequency for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.50 static uint32_t CLOCK_SYS_GetPdbFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.51 static uint32_t CLOCK_SYS_GetPitFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for PIT module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.52 **static uint32_t CLOCK_SYS_GetSpiFreq (uint32_t *instance*) [inline], [static]**

Gets the clock frequency for USB FS OTG module.

This function gets the clock frequency for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for USB FS OTG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

Gets the clock frequency for SPI module

This function gets the clock frequency for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.53 static uint32_t CLOCK_SYS_GetI2cFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.54 static uint32_t CLOCK_SYS_GetAdcAltFreq (uint32_t *instance*) [inline], [static]

This function gets the ADC alternate clock frequency.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq Current frequency.

12.6.55 `static uint32_t CLOCK_SYS_GetAdcAlt2Freq (uint32_t instance)`
[inline], [static]

This function gets the ADC alternate 2 clock frequency (ALTCLK2).

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq Current frequency.

12.6.56 `static uint32_t CLOCK_SYS_GetFtmFixedFreq (uint32_t instance)`
[inline], [static]

This function gets the FTM fixed frequency clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq Current frequency.

12.6.57 `static uint32_t CLOCK_SYS_GetFtmSystemClockFreq (uint32_t instance)`
[inline], [static]

This function gets the FTM's system clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

12.6.58 uint32_t CLOCK_SYS_GetFtmExternalFreq (uint32_t *instance*)

This function gets the FTM external clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq Current frequency.

12.6.59 static sim_ftm_clk_sel_t CLOCK_SYS_GetFtmExternalSrc (uint32_t *instance*) [inline], [static]

This function gets the FTM external clock source.

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | module device instance. |
|-----------------|-------------------------|

Returns

Ftm external clock source.

12.6.60 static void CLOCK_SYS_SetFtmExternalSrc (uint32_t *instance*, sim_ftm_clk_sel_t *ftmSrc*) [inline], [static]

This function sets the FTM external clock source.

Function Documentation

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | module device instance. |
| <i>ftmSrc</i> | FTM clock source setting. |

12.6.61 uint32_t CLOCK_SYS_GetUartFreq (uint32_t *instance*) [inline]

Get the UART clock frequency.

This function gets the clock frequency for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the UART clock frequency.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current frequency.

This function gets the clock frequency for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.62 static uint32_t CLOCK_SYS_GetGpioFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for GPIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for GPIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

**12.6.63 static void CLOCK_SYS_EnableDmaClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.64 static void CLOCK_SYS_DisableDmaClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.65 static bool CLOCK_SYS_GetDmaGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for DMA module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.66 static void CLOCK_SYS_EnableDmamuxClock (uint32_t *instance*) [inline], [static]

This function enables the clock for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.67 static void CLOCK_SYS_DisableDmamuxClock (uint32_t *instance*) [inline], [static]

This function disables the clock for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.68 static bool CLOCK_SYS_GetDmamuxGateCmd (uint32_t *instance*) [inline], [static]

This function will get the clock gate state for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.69 void CLOCK_SYS_EnablePortClock (uint32_t *instance*)

This function enables the clock for PORT module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.70 void CLOCK_SYS_DisablePortClock (uint32_t *instance*)

This function disables the clock for PORT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.71 bool CLOCK_SYS_GetPortGateCmd (uint32_t *instance*)

This function will get the clock gate state for PORT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.72 static void CLOCK_SYS_EnableEwmClock (uint32_t *instance*) [inline], [static]

This function enables the clock for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.73 static void CLOCK_SYS_DisableEwmClock (uint32_t *instance*) [inline], [static]

This function disables the clock for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.74 static bool CLOCK_SYS_GetEwmGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.75 static void CLOCK_SYS_EnableFtfClock (uint32_t *instance*) [inline],
[static]**

This function enables the clock for FTF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.76 static void CLOCK_SYS_DisableFtfClock (uint32_t *instance*) [inline],
[static]**

This function disables the clock for FTF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.77 static bool CLOCK_SYS_GetFtfGateCmd (uint32_t *instance*) [inline],
[static]**

This function will get the clock gate state for FTF module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.78 **static void CLOCK_SYS_EnableCrcClock (uint32_t *instance*) [inline], [static]**

This function enables the clock for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.79 **static void CLOCK_SYS_DisableCrcClock (uint32_t *instance*) [inline], [static]**

This function disables the clock for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.80 **static bool CLOCK_SYS_GetCrcGateCmd (uint32_t *instance*) [inline], [static]**

This function will get the clock gate state for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.81 void CLOCK_SYS_EnableAdcClock (uint32_t *instance*) [inline]

This function enables the clock for ADC module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.82 void CLOCK_SYS_DisableAdcClock (uint32_t *instance*) [inline]

This function disables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.83 bool CLOCK_SYS_GetAdcGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.84 static void CLOCK_SYS_EnableCmpClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.85 static void CLOCK_SYS_DisableCmpClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.86 static bool CLOCK_SYS_GetCmpGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.87 void CLOCK_SYS_EnableDacClock (uint32_t *instance*) [inline]

This function enables the clock for DAC module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for DAC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.88 void CLOCK_SYS_DisableDacClock (uint32_t *instance*) [inline]

This function disables the clock for DAC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for DAC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.89 bool CLOCK_SYS_GetDacGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for DAC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for DAC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.90 static void CLOCK_SYS_EnableVrefClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.91 static void CLOCK_SYS_DisableVrefClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.92 static bool CLOCK_SYS_GetVrefGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.93 static void CLOCK_SYS_EnablePdbClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for PDB module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.94 static void CLOCK_SYS_DisablePdbClock (uint32_t *instance*) [inline], [static]

This function disables the clock for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.95 static bool CLOCK_SYS_GetPdbGateCmd (uint32_t *instance*) [inline], [static]

This function will get the clock gate state for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.96 void CLOCK_SYS_EnableFtmClock (uint32_t *instance*) [inline]

This function enables the clock for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.97 void CLOCK_SYS_DisableFtmClock (uint32_t *instance*) [inline]

This function disables the clock for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.98 bool CLOCK_SYS_GetFtmGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for FTM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.99 static void CLOCK_SYS_EnablePitClock (uint32_t *instance*) [inline], [static]

This function enables the clock for PIT module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.100 **static void CLOCK_SYS_DisablePitClock (uint32_t *instance*)** **[inline], [static]**

This function disables the clock for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.101 **static bool CLOCK_SYS_GetPitGateCmd (uint32_t *instance*)** **[inline], [static]**

This function will get the clock gate state for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.102 **static void CLOCK_SYS_EnableLptmrClock (uint32_t *instance*)** **[inline], [static]**

Enable the clock for LPTMR module.

This function enables the clock for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for LPTMR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.103 static void CLOCK_SYS_DisableLptmrClock (uint32_t *instance*)
[inline], [static]**

Disable the clock for LPTMR module.

This function disables the clock for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for LPTMR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.104 static bool CLOCK_SYS_GetLptmrGateCmd (uint32_t *instance*)
[inline], [static]**

Get the the clock gate state for LPTMR module.

This function will get the clock gate state for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for LPTMR module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.105 void CLOCK_SYS_EnableSpiClock (uint32_t *instance*) [inline]

Enable the clock for USBFS module.

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Enable the clock for SPI module.

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for SPI moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.106 void CLOCK_SYS_DisableSpiClock (uint32_t *instance*) [inline]

This function disables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.107 bool CLOCK_SYS_GetSpiGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.108 void CLOCK_SYS_EnableI2cClock (uint32_t *instance*) [inline]

This function enables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for I2C module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.109 void CLOCK_SYS_DisableI2cClock (uint32_t *instance*) [inline]

This function disables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.110 bool CLOCK_SYS_GetI2cGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.111 void CLOCK_SYS_EnableUartClock (uint32_t *instance*) [inline]

This function enables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.112 void CLOCK_SYS_DisableUartClock (uint32_t *instance*) [inline]

This function disables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.113 bool CLOCK_SYS_GetUartGateCmd (uint32_t *instance*) [inline]

This function will get the clock gate state for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for UART module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.114 static void CLOCK_SYS_SetFtmExternalFreq (uint32_t *srcInstance*, uint32_t *freq*) [inline], [static]

This function sets the FTM external clock frequency (FTM_CLKx).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequency value. |

12.6.115 static void CLOCK_SYS_SetOutDiv3 (uint8_t *outdiv3*) [inline], [static]

This function sets divide value OUTDIV3.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv3</i> | Outdivider3 setting |
|----------------|---------------------|

12.6.116 static uint8_t CLOCK_SYS_GetOutDiv3 (void) [inline], [static]

This function gets divide value OUTDIV3.

Returns

Outdivider3 setting

12.6.117 uint32_t CLOCK_SYS_GetFlexbusFreq (void)

This function gets the flexbus clock frequency.

Returns

Current flexbus clock frequency.

12.6.118 `static uint32_t CLOCK_SYS_GetRtcFreq (uint32_t instance)`
`[inline], [static]`

This function gets the RTC input clock frequency.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

12.6.119 `uint32_t CLOCK_SYS_GetRtcOutFreq (void)`

This function gets the frequency of RTC_CLKOUT.

Returns

Current frequency.

12.6.120 `static clock_rtcout_src_t CLOCK_SYS_GetRtcOutSrc (void)` `[inline], [static]`

This function gets the source of RTC_CLKOUT. It is determined by RTCCLKOUTSEL.

Returns

Current source.

12.6.121 `static void CLOCK_SYS_SetRtcOutSrc (clock_rtcout_src_t src)` `[inline], [static]`

This function sets the source of RTC_CLKOUT.

Parameters

| | |
|------------|---------------------------|
| <i>src</i> | RTC_CLKOUT source to set. |
|------------|---------------------------|

12.6.122 `static clock_rmii_src_t CLOCK_SYS_GetEnetRmiiSrc (uint32_t instance)` `[inline], [static]`

This function gets the ethernet RMII clock source.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current source.

12.6.123 static void CLOCK_SYS_SetEnetRmiiSrc (uint32_t *instance*, clock_rmii_src_t *rmiiSrc*) [inline], [static]

This function sets the ethernet RMI clock source.

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | module device instance. |
| <i>rmiiSrc</i> | RMI clock source. |

12.6.124 uint32_t CLOCK_SYS_GetEnetRmiiFreq (uint32_t *instance*)

This function gets the ethernet RMI clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

12.6.125 uint32_t CLOCK_SYS_GetFlexcanFreq (uint32_t *instance*, clock_flexcan_src_t *flexcanSrc*)

This function gets the FLEXCAN clock frequency.

Function Documentation

Parameters

| | |
|-------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>flexcanSrc</i> | clock source |

Returns

Current frequency.

12.6.126 `static void CLOCK_SYS_SetEnetTimeStampSrc (uint32_t instance, clock_time_src_t timeSrc) [inline], [static]`

This function sets the ethernet timestamp clock source selection.

Parameters

| | |
|-----------------|----------------------------------|
| <i>instance</i> | module device instance. |
| <i>timeSrc</i> | Ethernet timestamp clock source. |

12.6.127 `static clock_time_src_t CLOCK_SYS_GetEnetTimeStampSrc (uint32_t instance) [inline], [static]`

This function gets the ethernet timestamp clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current source.

12.6.128 `uint32_t CLOCK_SYS_GetEnetTimeStampFreq (uint32_t instance)`

This function gets the ethernet timestamp clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

**12.6.129 static uint32_t CLOCK_SYS_GetCmtFreq (uint32_t *instance*)
[inline], [static]**

This function gets the clock frequency for CMT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.130 uint32_t CLOCK_SYS_GetSdhcFreq (uint32_t *instance*)

This function gets the clock frequency for SDHC.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module.

**12.6.131 static void CLOCK_SYS_SetSdhcSrc (uint32_t *instance*,
clock_sdhc_src_t *setting*) [inline], [static]**

This function sets the SDHC clock source selection.

Function Documentation

Parameters

| | |
|-----------------|-------------------|
| <i>instance</i> | IP instance. |
| <i>setting</i> | The value to set. |

12.6.132 `static clock_sdhc_src_t CLOCK_SYS_GetSdhcSrc (uint32_t instance)` `[inline], [static]`

This function gets the SDHC clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current selection.

12.6.133 `uint32_t CLOCK_SYS_GetSaiFreq (uint32_t instance, clock_sai_src_t saiSrc)`

This function gets the clock frequency for SAI.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | module device instance. |
| <i>saiSrc</i> | SAI clock source selection according to its internal register. |

Returns

freq clock frequency for this module.

12.6.134 `static uint32_t CLOCK_SYS_GetUsbdcdFreq (uint32_t instance)` `[inline], [static]`

This function gets the clock frequency for USB DCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

**12.6.135 static void CLOCK_SYS_EnableMpuClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for MPU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.136 static void CLOCK_SYS_DisableMpuClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for MPU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.137 static bool CLOCK_SYS_GetMpuGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for MPU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

Function Documentation

12.6.138 `static void CLOCK_SYS_EnableFlexbusClock (uint32_t instance)`
`[inline], [static]`

This function enables the clock for FLEXBUS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.139 static void CLOCK_SYS_DisableFlexbusClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for FLEXBUS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.140 static bool CLOCK_SYS_GetFlexbusGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for FLEXBUS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.141 static void CLOCK_SYS_EnableRngaClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for RNGA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.142 static void CLOCK_SYS_DisableRngaClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for RNGA module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.143 static bool CLOCK_SYS_GetRngaGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for RNGA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.144 static void CLOCK_SYS_EnableSaiClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for SAI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.145 static void CLOCK_SYS_DisableSaiClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for SAI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.146 static bool CLOCK_SYS_GetSaiGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for SAI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.147 static void CLOCK_SYS_EnableCmtClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for CMT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.148 static void CLOCK_SYS_DisableCmtClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for CMT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.149 static bool CLOCK_SYS_GetCmtGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for CMT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

Function Documentation

12.6.150 `static void CLOCK_SYS_EnableRtcClock (uint32_t instance)`
`[inline], [static]`

This function enables the clock for RTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.151 static void CLOCK_SYS_DisableRtcClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for RTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.152 static bool CLOCK_SYS_GetRtcGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for RTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.153 static void CLOCK_SYS_EnableEnetClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for ENET module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.154 static void CLOCK_SYS_DisableEnetClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for ENET module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.155 **static bool CLOCK_SYS_GetEnetGateCmd (uint32_t *instance*)** **[inline], [static]**

This function will get the clock gate state for ENET module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.156 **static void CLOCK_SYS_EnableFlexcanClock (uint32_t *instance*)** **[inline]**

This function enables the clock for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.157 **static void CLOCK_SYS_DisableFlexcanClock (uint32_t *instance*)** **[inline]**

This function disables the clock for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.158 static bool CLOCK_SYS_GetFlexcanGateCmd (uint32_t *instance*)
[inline]**

This function will get the clock gate state for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for FLEXCAN module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.159 static void CLOCK_SYS_EnableSdhcClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for SDHC module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.160 static void CLOCK_SYS_DisableSdhcClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for SDHC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.161 static bool CLOCK_SYS_GetSdhcGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for SDHC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.162 static void CLOCK_SYS_EnableTsiClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for TSI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.163 static void CLOCK_SYS_DisableTsiClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for TSI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.164 static bool CLOCK_SYS_GetTsiGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for TSI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.165 static void CLOCK_SYS_EnableLlwuClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for LLWU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.166 static void CLOCK_SYS_DisableLlwuClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for LLWU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.167 static bool CLOCK_SYS_GetLlwuGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for LLWU module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.168 static void CLOCK_SYS_SetEnetExternalFreq (uint32_t *srcInstance*, uint32_t *freq*) [inline], [static]

This function sets the ENET external clock frequency (ENET_1588_CLKIN).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequency value. |

12.6.169 static void CLOCK_SYS_SetSdhcExternalFreq (uint32_t *srcInstance*, uint32_t *freq*) [inline], [static]

This function sets the SDHC external clock frequency (SDHC_CLKIN).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequency value. |

12.6.170 uint32_t CLOCK_SYS_GetUsbfsFreq (uint32_t *instance*)

Gets the clock frequency for USBFS module.

This function gets the clock frequency for USB FS OTG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the clock frequency for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.171 static void CLOCK_SYS_SetUsbfsDiv (uint32_t *instance*, uint8_t *usbdiv*, uint8_t *usbfrac*) [inline], [static]

This function sets USB FS divider setting. Divider output clock = Divider input clock * [(USBFSFRAC+1) / (USBFSDIV+1)]

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | USB FS module instance. |
| <i>usbdiv</i> | Value of USBFSDIV. |
| <i>usbfrac</i> | Value of USBFSFRAC. |

12.6.172 static void CLOCK_SYS_GetUsbfsDiv (uint32_t *instance*, uint8_t * *usbdiv*, uint8_t * *usbfrac*) [inline], [static]

This function gets USB FS divider setting. Divider output clock = Divider input clock * [(USBFSFRAC+1) / (USBFSDIV+1)]

Parameters

Function Documentation

| | |
|-----------------|-------------------------|
| <i>instance</i> | USB FS module instance. |
| <i>usbdiv</i> | Value of USBFSDIV. |
| <i>usbfrac</i> | Value of USBFSFRAC. |

12.6.173 static void CLOCK_SYS_EnableUsbfsClock (uint32_t *instance*) [inline], [static]

This function enables the clock for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.174 static void CLOCK_SYS_DisableUsbfsClock (uint32_t *instance*) [inline], [static]

This function disables the clock for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.175 static bool CLOCK_SYS_GetUsbfsGateCmd (uint32_t *instance*) [inline], [static]

Get the the clock gate state for USBFS module.

This function will get the clock gate state for USB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.176 static void CLOCK_SYS_EnableUsbdcdClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for USBDCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.177 static void CLOCK_SYS_DisableUsbdcdClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for USBDCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.178 static bool CLOCK_SYS_GetUsbdcdGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for USBDCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

Function Documentation

12.6.179 `static clock_usbfs_src_t CLOCK_SYS_GetUsbfsSrc (uint32_t instance) [inline], [static]`

Gets the clock source for USBFS module.

This function gets the clock source for USB FS OTG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Clock source.

This function gets the clock source for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.180 `static void CLOCK_SYS_SetUsbfsSrc (uint32_t instance, clock_usbfs_src_t usbfsSrc) [inline], [static]`

Sets the clock source for USBFS module.

This function sets the clock source for USB FS OTG module.

Parameters

| | |
|-----------------|------------------------------|
| <i>instance</i> | module device instance. |
| <i>usbfsSrc</i> | USB FS clock source setting. |

This function sets the clock source for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
| <i>usbfsSrc</i> | Clock source to set. |

12.6.181 void CLOCK_SYS_Osc0Deinit (void)

This function deinitializes OSC0.

**12.6.182 static void CLOCK_SYS_SetUsbExternalFreq (uint32_t *srcInstance*,
uint32_t *freq*) [inline], [static]**

This function sets the USB external clock frequency (USB_CLKIN).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequcney value. |

**12.6.183 static clock_lpuart_src_t CLOCK_SYS_GetLpuartSrc (uint32_t *instance*)
[inline], [static]**

This function gets the clock source for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Clock source.

This function gets the clock source for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Function Documentation

Returns

source Clock source for this module.

12.6.184 static void CLOCK_SYS_SetLpuartSrc (uint32_t *instance*, clock_lpuart_src_t *lpuartSrc*) [inline], [static]

This function sets the clock source for LPUART module.

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>lpuartSrc</i> | Clock source. |

This function sets the clock source for LPUART module.

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>lpuartSrc</i> | Clock source to set. |

12.6.185 uint32_t CLOCK_SYS_GetLpuartFreq (uint32_t *instance*)

Get the LPUART clock frequency.

This function gets the clock frequency for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the LPUART clock frequency.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current frequency.

**12.6.186 static void CLOCK_SYS_EnableLpuartClock (uint32_t *instance*)
[inline], [static]**

Enable the clock for UART module.

This function enables the clock for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.187 static void CLOCK_SYS_DisableLpuartClock (uint32_t *instance*)
[inline], [static]**

Disable the clock for UART module.

This function disables the clock for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Function Documentation

12.6.188 static bool CLOCK_SYS_GetLpuartGateCmd (uint32_t *instance*) [inline], [static]

Get the the clock gate state for UART module.

This function will get the clock gate state for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.189 uint32_t CLOCK_SYS_GetPIIFllDivClockFreq (void)

This function gets the frequency of the PLL/FLL clock divided by the fractional divider configured by SIM_CLKDIV3[PLLFLFRAC, PLLFLLDIV].

Returns

Current clock frequency.

12.6.190 uint32_t CLOCK_SYS_GetTpmFreq (uint32_t *instance*)

Gets the clock frequency for TPM module.

This function gets the TPM clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

This function gets the clock frequency for TPM module.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current frequency.

This function gets the clock frequency for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.191 static void CLOCK_SYS_SetTpmSrc (uint32_t *instance*, clock_tpm_src_t *tpmSrc*) [inline], [static]

Sets the clock source for TPM module.

This function sets the TPM clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Function Documentation

| | |
|---------------|-------------------|
| <i>tpmSrc</i> | The value to set. |
|---------------|-------------------|

This function sets the clock source for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
| <i>tpmSrc</i> | Clock source to set. |

12.6.192 `static clock_tpm_src_t CLOCK_SYS_GetTpmSrc (uint32_t instance)` `[inline], [static]`

Gets the clock source for TPM module.

This function gets the TPM clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current selection.

This function gets the clock source for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.193 `uint32_t CLOCK_SYS_GetTpmExternalFreq (uint32_t instance)`

Gets the external clock frequency for TPM module.

Gets Tpm external clock frequency.

This function gets the TPM external clock source frequency.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

TPM external clock frequency.

This function will get the Tpm external clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

This function gets the external clock frequency for TPM module.

Parameters

| | |
|-----------------|-------------------------|
| <i>instance</i> | module device instance. |
|-----------------|-------------------------|

Returns

freq External clock frequency.

12.6.194 static void CLOCK_SYS_SetTpmExternalSrc (uint32_t *instance*, sim_tpm_clk_sel_t *src*) [inline], [static]

This function sets the TPM external clock source selection.

Parameters

| | |
|-----------------|----------------------------|
| <i>instance</i> | IP instance. |
| <i>src</i> | TPM external clock source. |

Function Documentation

12.6.195 `static sim_tpm_clk_sel_t CLOCK_SYS_GetTpmExternalSrc (uint32_t instance) [inline], [static]`

This function sets the TPM external clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

setting Current TPM external clock source.

12.6.196 `static clock_usbhs_slowclk_src_t CLOCK_SYS_GetUsbhsSlowClockSrc (uint32_t instance) [inline], [static]`

This function gets the slow clock source for USB HS/USB PHY module, used to detect wakeup and resume events.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Clock source.

12.6.197 `static void CLOCK_SYS_SetUsbhsSlowClockSrc (uint32_t instance, clock_usbhs_slowclk_src_t usbhsSrc) [inline], [static]`

This function sets the clock source for USB HS/USB PHY module, used to detect wakeup and resume events.

Parameters

| | |
|-----------------|------------------------------|
| <i>instance</i> | module device instance. |
| <i>usbhsSrc</i> | USB FS clock source setting. |

12.6.198 uint32_t CLOCK_SYS_GetUsbhsSlowClockFreq (uint32_t *instance*)

This function gets the clock frequency for USB HS/USB PHY module, used to detect wakeup and resume events.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

**12.6.199 static void CLOCK_SYS_EnableSdramcClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for SDRAMC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.200 static void CLOCK_SYS_DisableSdramcClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for SDRAMC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.201 static bool CLOCK_SYS_GetSdramcGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for SDRAMC module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.202 void CLOCK_SYS_EnableTpmClock (uint32_t *instance*)

This function enables the clock for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for TPM module

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

12.6.203 void CLOCK_SYS_DisableTpmClock (uint32_t *instance*)

This function disables the clock for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for TPM module

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

12.6.204 bool CLOCK_SYS_GetTpmGateCmd (uint32_t *instance*)

This function will get the clock gate state for TPM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for TPM module.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.205 static void CLOCK_SYS_EnableUsbhsClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for USBHS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.206 static void CLOCK_SYS_DisableUsbhsClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for USBHS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.207 static bool CLOCK_SYS_GetUsbhsGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for USBHS module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.208 `static void CLOCK_SYS_EnableUsbphyClock (uint32_t instance)` `[inline], [static]`

This function enables the clock for USBPHY module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.209 `static void CLOCK_SYS_DisableUsbphyClock (uint32_t instance)` `[inline], [static]`

This function disables the clock for USBPHY module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.210 `static bool CLOCK_SYS_GetUsbphyGateCmd (uint32_t instance)` `[inline], [static]`

This function will get the clock gate state for USBPHY module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.211 `static void CLOCK_SYS_EnableUsbhsdcdClock (uint32_t instance)`
`[inline], [static]`

This function enables the clock for USBHSDCD module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.212 static void CLOCK_SYS_DisableUsbhsdcdClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for USBHSDCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.213 static bool CLOCK_SYS_GetUsbhsdcdGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for USBHSDCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.214 static clock_emvsim_src_t CLOCK_SYS_GetEmvsimSrc (uint32_t *instance*) [inline], [static]

This function gets the clock source for EMVSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Clock source.

12.6.215 `static void CLOCK_SYS_SetEmvsimSrc (uint32_t instance,
clock_emvsim_src_t emvsimSrc) [inline], [static]`

This function sets the clock source for EMVSIM module.

Function Documentation

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>emvsimSrc</i> | Clock source. |

12.6.216 uint32_t CLOCK_SYS_GetEmvsimFreq (uint32_t *instance*)

This function gets the clock frequency for EMVSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.217 uint32_t CLOCK_SYS_GetFlexioFreq (uint32_t *instance*)

Gets the clock frequency for FLEXIO module.

This function gets the FLEXIO clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

Current frequency.

This function gets the clock frequency for FLEXIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.218 static void CLOCK_SYS_SetFlexioSrc (uint32_t *instance*, clock_flexio_src_t *flexioSrc*) [inline], [static]

Sets the clock source for FLEXIO module.

This function sets the FLEXIO clock source selection.

Parameters

| | |
|------------------|-------------------|
| <i>instance</i> | IP instance. |
| <i>flexioSrc</i> | The value to set. |

This function sets the clock source for FLEXIO module.

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>flexioSrc</i> | Clock source to set. |

12.6.219 static clock_flexio_src_t CLOCK_SYS_GetFlexioSrc (uint32_t *instance*) [inline], [static]

Gets the clock source for FLEXIO module.

This function gets the FLEXIO clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current selection.

This function gets the clock source for FLEXIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

Function Documentation

12.6.220 `uint32_t CLOCK_SYS_GetQspiFreq (uint32_t instance, clock_qspi_src_t qspiSrc)`

This function gets the clock frequency for QSPI.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | module device instance. |
| <i>qspiSrc</i> | QSPI clock source selection according to its internal register. |

Returns

freq clock frequency for this module.

12.6.221 void CLOCK_SYS_EnableEmvsimClock (uint32_t instance)

This function enables the clock for EMVSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.222 void CLOCK_SYS_DisableEmvsimClock (uint32_t instance)

This function disables the clock for EMVSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.223 bool CLOCK_SYS_GetEmvsimGateCmd (uint32_t instance)

This function will get the clock gate state for EMVSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.224 static void CLOCK_SYS_EnableQspiClock (uint32_t instance)
[inline], [static]**

This function enables the clock for QSPI module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.225 static void CLOCK_SYS_DisableQspiClock (uint32_t *instance*)
[inline], [static]

This function disables the clock for QSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.226 static bool CLOCK_SYS_GetQspiGateCmd (uint32_t *instance*)
[inline], [static]

This function will get the clock gate state for QSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.227 static void CLOCK_SYS_EnableFlexioClock (uint32_t *instance*)
[inline], [static]

This function enables the clock for FLEXIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.228 static void CLOCK_SYS_DisableFlexioClock (uint32_t *instance*)
[inline], [static]

This function disables the clock for FLEXIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.229 static bool CLOCK_SYS_GetFlexioGateCmd (uint32_t *instance*)
[inline], [static]**

Get the the clock gate state for FLEXIO module.

This function will get the clock gate state for FLEXIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.230 static void CLOCK_SYS_EnableTrngClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for TRNG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.231 static void CLOCK_SYS_DisableTrngClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for TRNG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Function Documentation

12.6.232 `static bool CLOCK_SYS_GetTrngGateCmd (uint32_t instance)` `[inline], [static]`

Get the the clock gate state for TRNG module.

This function will get the clock gate state for TRNG module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.233 `void CLOCK_SYS_EnableLtcClock (uint32_t instance)`

This function enables the clock for LTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.234 `void CLOCK_SYS_DisableLtcClock (uint32_t instance)`

This function disables the clock for LTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.235 `bool CLOCK_SYS_GetLtcGateCmd (uint32_t instance)`

This function will get the clock gate state for LTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.236 uint32_t CLOCK_SYS_GetFllClockFreq (void)

This function gets the frequency of the MCGFLLCLK.

Returns

Current clock frequency.

12.6.237 uint32_t CLOCK_SYS_GetCopFreq (uint32_t instance, clock_cop_src_t copSrc)

This function gets the COP clock frequency.

Parameters

| | |
|-----------------|-----------------------------|
| <i>instance</i> | module device instance |
| <i>copSrc</i> | COP clock source selection. |

Returns

Current frequency.

12.6.238 uint32_t CLOCK_SYS_GetLpSciFreq (uint32_t instance)

This function gets the clock frequency for LPSCI module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.239 `static void CLOCK_SYS_SetLpSciSrc (uint32_t instance, clock_lpSci_src_t lpSciSrc) [inline], [static]`

This function sets the LPSCI clock source selection.

Parameters

| | |
|-----------------|-------------------|
| <i>instance</i> | IP instance. |
| <i>lpSciSrc</i> | The value to set. |

12.6.240 `static clock_lpSci_src_t CLOCK_SYS_GetLpSciSrc (uint32_t instance) [inline], [static]`

This function gets the LPSCI clock source selection.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current selection.

12.6.241 `void CLOCK_SYS_EnableLpSciClock (uint32_t instance)`

This function enables the clock for LPSCI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.242 void CLOCK_SYS_DisableLpisciClock (uint32_t *instance*)

This function disables the clock for LPSCI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.243 bool CLOCK_SYS_GetLpisciGateCmd (uint32_t *instance*)

This function will get the clock gate state for LPSCI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.244 static void CLOCK_SYS_SetTpmExternalFreq (uint32_t *srcInstance*,
uint32_t *freq*) [inline], [static]**

This function sets the TPM external clock frequency (TPM_CLKx).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequcney value. |

12.6.245 uint32_t CLOCK_SYS_GetCopFreq (void)

This function gets the COP clock frequency.

Returns

Current frequency.

Function Documentation

12.6.246 `static void CLOCK_SYS_SetCopSrc (clock_cop_src_t copSrc)`
`[inline], [static]`

This function sets the COP clock source selection.

Parameters

| | |
|---------------|-------------------|
| <i>copSrc</i> | The value to set. |
|---------------|-------------------|

12.6.247 static clock_cop_src_t CLOCK_SYS_GetCopSrc (void) [inline], [static]

This function gets the COP clock source selection.

Returns

Current selection.

12.6.248 void CLOCK_SYS_EnableXrdcClock (uint32_t instance)

This function enables the clock for XRDC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.249 void CLOCK_SYS_DisableXrdcClock (uint32_t instance)

This function disables the clock for XRDC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.250 bool CLOCK_SYS_GetXrdcGateCmd (uint32_t instance)

This function will get the clock gate state for XRDC module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.251 void CLOCK_SYS_EnableSemaClock (uint32_t *instance*)

This function enables the clock for SEMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.252 void CLOCK_SYS_DisableSemaClock (uint32_t *instance*)

This function disables the clock for SEMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.253 bool CLOCK_SYS_GetSemaGateCmd (uint32_t *instance*)

This function will get the clock gate state for SEMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.254 void CLOCK_SYS_EnableFlashClock (uint32_t *instance*)

This function enables the clock for FLASH module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.255 void CLOCK_SYS_DisableFlashClock (uint32_t *instance*)

This function disables the clock for FLASH module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.256 bool CLOCK_SYS_GetFlashGateCmd (uint32_t *instance*)

This function will get the clock gate state for FLASH module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.257 void CLOCK_SYS_EnableMuClock (uint32_t *instance*)

This function enables the clock for MU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.258 void CLOCK_SYS_DisableMuClock (uint32_t *instance*)

This function disables the clock for MU module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.259 bool CLOCK_SYS_GetMuGateCmd (uint32_t *instance*)

This function will get the clock gate state for MU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.260 void CLOCK_SYS_EnableIntmuxClock (uint32_t *instance*)

This function enables the clock for INTMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.261 void CLOCK_SYS_DisableIntmuxClock (uint32_t *instance*)

This function disables the clock for INTMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.262 bool CLOCK_SYS_GetIntmuxGateCmd (uint32_t *instance*)

This function will get the clock gate state for INTMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.263 clock_pit_src_t CLOCK_SYS_GetPitSrc (uint32_t *instance*)

This function gets the clock source for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.264 void CLOCK_SYS_SetPitSrc (uint32_t *instance*, clock_pit_src_t *pitSrc*)

This function sets the clock source for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
| <i>pitSrc</i> | Clock source to set. |

12.6.265 void CLOCK_SYS_EnableLpspiClock (uint32_t *instance*)

This function enables the clock for LPSPI module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.266 void CLOCK_SYS_DisableLpspiClock (uint32_t *instance*)

This function disables the clock for LPSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.267 bool CLOCK_SYS_GetLpspiGateCmd (uint32_t *instance*)

This function will get the clock gate state for LPSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.268 clock_lpspi_src_t CLOCK_SYS_GetLpspiSrc (uint32_t *instance*)

This function gets the clock source for LPSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.269 void CLOCK_SYS_SetLpspiSrc (uint32_t *instance*, clock_lpspi_src_t *lpspiSrc*)

This function sets the clock source for LPSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
| <i>lpspiSrc</i> | Clock source to set. |

12.6.270 `uint32_t CLOCK_SYS_GetLpspiFreq (uint32_t instance)`

This function gets the clock frequency for LPSPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.271 `void CLOCK_SYS_EnableLpi2cClock (uint32_t instance)`

This function enables the clock for LPI2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.272 `void CLOCK_SYS_DisableLpi2cClock (uint32_t instance)`

This function disables the clock for LPI2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.273 `bool CLOCK_SYS_GetLpi2cGateCmd (uint32_t instance)`

This function will get the clock gate state for LPI2C module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.274 `clock_lpi2c_src_t` `CLOCK_SYS_GetLpi2cSrc (uint32_t instance)`

This function gets the clock source for LPI2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.275 `void` `CLOCK_SYS_SetLpi2cSrc (uint32_t instance, clock_lpi2c_src_t lpi2cSrc)`

This function sets the clock source for LPI2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
| <i>lpi2cSrc</i> | Clock source to set. |

12.6.276 `uint32_t` `CLOCK_SYS_GetLpi2cFreq (uint32_t instance)`

This function gets the clock frequency for LPI2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.277 void CLOCK_SYS_EnableEvmsimClock (uint32_t *instance*)

This function enables the clock for EVMSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.278 void CLOCK_SYS_DisableEvmsimClock (uint32_t *instance*)

This function disables the clock for EVMSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.279 bool CLOCK_SYS_GetEvmsimGateCmd (uint32_t *instance*)

This function will get the clock gate state for EVMSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.280 clock_evmsim_src_t CLOCK_SYS_GetEvmsimSrc (uint32_t *instance*)

This function gets the clock source for EVMSIM module.

Function Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

source Clock source for this module.

12.6.281 void CLOCK_SYS_SetEvmsimSrc (uint32_t *instance*, clock_evmsim_src_t *evmsimSrc*)

This function sets the clock source for EVMSIM module.

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>evmsimSrc</i> | Clock source to set. |

12.6.282 uint32_t CLOCK_SYS_GetEvmsimFreq (uint32_t *instance*)

This function gets the clock frequency for EVMSIM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.283 void CLOCK_SYS_EnableAtxClock (uint32_t *instance*)

This function enables the clock for ATX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.284 void CLOCK_SYS_DisableAtxClock (uint32_t instance)

This function disables the clock for ATX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.285 bool CLOCK_SYS_GetAtxGateCmd (uint32_t instance)

This function will get the clock gate state for ATX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.286 static void CLOCK_SYS_SetOutDiv5 (uint8_t outdiv5) [inline], [static]

This function sets divide value OUTDIV5.

Parameters

| | |
|----------------|---------------------|
| <i>outdiv5</i> | Outdivider5 setting |
|----------------|---------------------|

12.6.287 static uint8_t CLOCK_SYS_GetOutDiv5 (void) [inline], [static]

This function gets divide value OUTDIV5.

Returns

Outdivider5 setting

Function Documentation

12.6.288 uint32_t CLOCK_SYS_GetOutdiv5ClockFreq (void)

This function gets the OUTDIV5 output clock for ADC.

Returns

freq Current frequency.

12.6.289 uint32_t CLOCK_SYS_GetFastPeripheralClockFreq (void)

This function gets the fast peripheral clock frequency.

Returns

Current clock frequency.

12.6.290 uint32_t CLOCK_SYS_GetDmaFreq (uint32_t *instance*)

This function gets the clock frequency for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.291 uint32_t CLOCK_SYS_GetDmamuxFreq (uint32_t *instance*)

This function gets the clock frequency for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.292 uint32_t CLOCK_SYS_GetAdcFreq (uint32_t *instance*)

This function gets the clock frequency for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.293 uint32_t CLOCK_SYS_GetPwmFreq (uint32_t *instance*)

This function gets the clock frequency for eFlexPWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.294 uint32_t CLOCK_SYS_GetEncFreq (uint32_t *instance*)

This function gets the clock frequency for ENC module.

Parameters

Function Documentation

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.295 uint32_t CLOCK_SYS_GetXbarFreq (uint32_t *instance*)

This function gets the clock frequency for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.296 uint32_t CLOCK_SYS_GetAoiFreq (uint32_t *instance*)

This function gets the clock frequency for AOI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.6.297 uint32_t CLOCK_SYS_GetFlexcanFreq (uint8_t *instance*, clock_flexcan_src_t *flexcanSrc*)

This function gets the FLEXCAN clock frequency.

Parameters

| | |
|-------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>flexcanSrc</i> | clock source |

Returns

Current frequency.

**12.6.298 static void CLOCK_SYS_EnablePwmClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for eFlexPWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.299 static void CLOCK_SYS_DisablePwmClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for eFlexPWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.300 static bool CLOCK_SYS_GetPwmGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for eFlexPWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Function Documentation

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.301 static void CLOCK_SYS_EnableAoiClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for AOI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.302 static void CLOCK_SYS_DisableAoiClock (uint32_t *instance*)
[inline], [static]**

This function disables the clock for AOI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.303 static bool CLOCK_SYS_GetAoiGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for AOI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

**12.6.304 static void CLOCK_SYS_EnableXbarClock (uint32_t *instance*)
[inline], [static]**

This function enables the clock for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.305 static void CLOCK_SYS_DisableXbarClock (uint32_t *instance*)
[inline], [static]

This function disables the clock for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.306 static bool CLOCK_SYS_GetXbarGateCmd (uint32_t *instance*)
[inline], [static]

This function will get the clock gate state for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.6.307 static void CLOCK_SYS_EnableEncClock (uint32_t *instance*)
[inline], [static]

This function enables the clock for ENC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.6.308 static void CLOCK_SYS_DisableEncClock (uint32_t *instance*)
[inline], [static]

This function disables the clock for ENC module.

Variable Documentation

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.6.309 static bool CLOCK_SYS_GetEncGateCmd (uint32_t *instance*)
[inline], [static]**

This function will get the clock gate state for ENC moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.7 Variable Documentation

12.7.1 SIM_Type* const g_simBase[]

12.7.2 MCG_Type* const g_mcgBase[]

12.7.3 OSC_Type* const g_oscBase[]

12.8 K02F12810

The data structure definition for K02F12810 Clock Manager.

12.8.1 Overview

Files

- file [fsl_clock_MK02F12810.h](#)

Data Structures

- struct [sim_config_k02f12810_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency.

12.8.2 Data Structure Documentation

12.8.2.1 struct sim_config_k02f12810_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

K02F12810

12.8.2.1.0.17 Field Documentation

12.8.2.1.0.17.1 `clock_pllflr_sel_t sim_config_k02f12810_t::pllFlrSel`

12.8.2.1.0.17.2 `clock_er32k_src_t sim_config_k02f12810_t::er32kSrc`

12.8.2.1.0.17.3 `uint8_t sim_config_k02f12810_t::outdiv4`

12.8.3 Macro Definition Documentation

12.8.3.1 `#define FTM_EXT_CLK_COUNT 2`

12.8.4 Variable Documentation

12.8.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

12.9 K10D10

The data structure definition for K10D10 Clock Manager.

12.9.1 Overview

Files

- file [fsl_clock_MK10D10.h](#)

Data Structures

- struct [sim_config_k10d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.9.2 Data Structure Documentation

12.9.2.1 struct [sim_config_k10d10_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

K10D10

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.9.2.1.0.18 Field Documentation

12.9.2.1.0.18.1 `clock_pllfl_sel_t sim_config_k10d10_t::pllFlSel`

12.9.2.1.0.18.2 `clock_er32k_src_t sim_config_k10d10_t::er32kSrc`

12.9.2.1.0.18.3 `uint8_t sim_config_k10d10_t::outdiv4`

12.9.3 Macro Definition Documentation

12.9.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.9.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.9.3.3 `#define USB_EXT_CLK_COUNT 1`

12.9.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.9.4 Variable Documentation

12.9.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.9.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

12.10 K11DA5

The data structure definition for K11DA5 Clock Manager.

12.10.1 Overview

Files

- file [fsl_clock_MK11DA5.h](#)

Data Structures

- struct [sim_config_k11da5_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.
- #define [CLOCK_CONFIG_NUM](#) 2
Default clock configuration number.
- #define [CLOCK_CONFIG_INDEX_FOR_VLPR](#) 0
Clock configuration index for VLPR mode.
- #define [CLOCK_CONFIG_INDEX_FOR_RUN](#) 1
Clock configuration index for RUN mode.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.10.2 Data Structure Documentation

12.10.2.1 struct sim_config_k11da5_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

K11DA5

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.10.2.1.0.19 Field Documentation

12.10.2.1.0.19.1 `clock_pllfl_sel_t sim_config_k11da5_t::pllFlSel`

12.10.2.1.0.19.2 `clock_er32k_src_t sim_config_k11da5_t::er32kSrc`

12.10.2.1.0.19.3 `uint8_t sim_config_k11da5_t::outdiv4`

12.10.3 Macro Definition Documentation

12.10.3.1 `#define USB_EXT_CLK_COUNT 1`

12.10.3.2 `#define FTM_EXT_CLK_COUNT 2`

12.10.3.3 `#define CLOCK_CONFIG_NUM 2`

12.10.3.4 `#define CLOCK_CONFIG_INDEX_FOR_VLPR 0`

12.10.3.5 `#define CLOCK_CONFIG_INDEX_FOR_RUN 1`

12.10.4 Variable Documentation

12.10.4.1 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.10.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

12.11 K128T7

The data structure definition for K128T7 Clock Manager.

12.11.1 Overview

Files

- file [fsl_clock_MKL28T7.h](#)

Data Structures

- struct [sim_config_kl28t7_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [CLOCK_CONFIG_NUM](#) 2
Default clock configuration number.
- #define [CLOCK_CONFIG_INDEX_FOR_VLPR](#) 0
Clock configuration index for VLPR mode.
- #define [CLOCK_CONFIG_INDEX_FOR_RUN](#) 1
Clock configuration index for RUN mode.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency([TPM_CLK](#)).

12.15.4 Variable Documentation

12.15.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.15.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.15.4.3 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K22F12810

12.16 K22F12810

The data structure definition for K22F12810 Clock Manager.

12.16.1 Overview

Files

- file [fsl_clock_MK22F12810.h](#)

Data Structures

- struct [sim_config_k22f12810_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency.
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency.

12.16.2 Data Structure Documentation

12.16.2.1 struct sim_config_k22f12810_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.16.2.1.0.24 Field Documentation

12.16.2.1.0.24.1 `clock_pllfl_sel_t sim_config_k22f12810_t::pllFlSel`

12.16.2.1.0.24.2 `clock_er32k_src_t sim_config_k22f12810_t::er32kSrc`

12.16.2.1.0.24.3 `uint8_t sim_config_k22f12810_t::outdiv4`

12.16.3 Macro Definition Documentation

12.16.3.1 `#define USB_EXT_CLK_COUNT 1`

12.16.3.2 `#define FTM_EXT_CLK_COUNT 2`

12.16.4 Variable Documentation

12.16.4.1 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.16.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K22F25612

12.17 K22F25612

The data structure definition for K22F25612 Clock Manager.

12.17.1 Overview

Files

- file [fsl_clock_MK22F25612.h](#)

Data Structures

- struct [sim_config_k22f25612_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency.
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency.

12.17.2 Data Structure Documentation

12.17.2.1 struct sim_config_k22f25612_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.17.2.1.0.25 Field Documentation

12.17.2.1.0.25.1 `clock_pllfl_sel_t sim_config_k22f25612_t::pllFlSel`

12.17.2.1.0.25.2 `clock_er32k_src_t sim_config_k22f25612_t::er32kSrc`

12.17.2.1.0.25.3 `uint8_t sim_config_k22f25612_t::outdiv4`

12.17.3 Macro Definition Documentation

12.17.3.1 `#define USB_EXT_CLK_COUNT 1`

12.17.3.2 `#define FTM_EXT_CLK_COUNT 2`

12.17.4 Variable Documentation

12.17.4.1 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.17.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K22F51212

12.18 K22F51212

The data structure definition for K22F51212 Clock Manager.

12.18.1 Overview

Files

- file [fsl_clock_MK22F51212.h](#)

Data Structures

- struct [sim_config_k22f51212_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency.
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency.

12.18.2 Data Structure Documentation

12.18.2.1 struct sim_config_k22f51212_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.18.2.1.0.26 Field Documentation

12.18.2.1.0.26.1 `clock_pllfl_sel_t sim_config_k22f51212_t::pllFlSel`

12.18.2.1.0.26.2 `clock_er32k_src_t sim_config_k22f51212_t::er32kSrc`

12.18.2.1.0.26.3 `uint8_t sim_config_k22f51212_t::outdiv4`

12.18.3 Macro Definition Documentation

12.18.3.1 `#define USB_EXT_CLK_COUNT 1`

12.18.3.2 `#define FTM_EXT_CLK_COUNT 2`

12.18.4 Variable Documentation

12.18.4.1 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.18.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K22FA12

12.19 K22FA12

The data structure definition for K22FA12 Clock Manager.

12.19.1 Overview

Files

- file [fsl_clock_MK22FA12.h](#)

Data Structures

- struct [sim_config_k22fa12_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency(SDHC_CLKIN).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.19.2 Data Structure Documentation

12.19.2.1 struct sim_config_k22fa12_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlISel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.

- uint8_t [outdiv4](#)
OUTDIV setting.

12.19.2.1.0.27 Field Documentation

12.19.2.1.0.27.1 clock_pllfl_sel_t sim_config_k22fa12_t::pllFlSel

12.19.2.1.0.27.2 clock_er32k_src_t sim_config_k22fa12_t::er32kSrc

12.19.2.1.0.27.3 uint8_t sim_config_k22fa12_t::outdiv4

12.19.3 Macro Definition Documentation

12.19.3.1 #define SDHC_EXT_CLK_COUNT 1

12.19.3.2 #define USB_EXT_CLK_COUNT 1

12.19.3.3 #define FTM_EXT_CLK_COUNT 2

12.19.4 Variable Documentation

12.19.4.1 uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]

12.19.4.2 uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]

12.19.4.3 uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]

K24F12

12.20 K24F12

The data structure definition for K24F12 Clock Manager.

12.20.1 Overview

Files

- file [fsl_clock_MK24F12.h](#)

Data Structures

- struct [sim_config_k24f12_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency(SDHC_CLKIN).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.20.2 Data Structure Documentation

12.20.2.1 struct sim_config_k24f12_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlISel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.

- uint8_t `outdiv4`
OUTDIV setting.

12.20.2.1.0.28 Field Documentation

12.20.2.1.0.28.1 `clock_pllfl_sel_t sim_config_k24f12_t::pllFlSel`

12.20.2.1.0.28.2 `clock_er32k_src_t sim_config_k24f12_t::er32kSrc`

12.20.2.1.0.28.3 `uint8_t sim_config_k24f12_t::outdiv4`

12.20.3 Macro Definition Documentation

12.20.3.1 `#define SDHC_EXT_CLK_COUNT 1`

12.20.3.2 `#define USB_EXT_CLK_COUNT 1`

12.20.3.3 `#define FTM_EXT_CLK_COUNT 2`

12.20.4 Variable Documentation

12.20.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.20.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.20.4.3 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K24F25612

12.21 K24F25612

The data structure definition for K24F25612 Clock Manager.

12.21.1 Overview

Files

- file [fsl_clock_MK24F25612.h](#)

Data Structures

- struct [sim_config_k24f25612_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.21.2 Data Structure Documentation

12.21.2.1 struct sim_config_k24f25612_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.21.2.1.0.29 Field Documentation

12.21.2.1.0.29.1 `clock_pllfl_sel_t sim_config_k24f25612_t::pllFlSel`

12.21.2.1.0.29.2 `clock_er32k_src_t sim_config_k24f25612_t::er32kSrc`

12.21.2.1.0.29.3 `uint8_t sim_config_k24f25612_t::outdiv4`

12.21.3 Macro Definition Documentation

12.21.3.1 `#define USB_EXT_CLK_COUNT 1`

12.21.3.2 `#define FTM_EXT_CLK_COUNT 2`

12.21.4 Variable Documentation

12.21.4.1 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.21.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K30D10

12.22 K30D10

The data structure definition for K30D10 Clock Manager.

12.22.1 Overview

Files

- file [fsl_clock_MK30D10.h](#)

Data Structures

- struct [sim_config_k30d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.22.2 Data Structure Documentation

12.22.2.1 struct sim_config_k30d10_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.22.2.1.0.30 Field Documentation

12.22.2.1.0.30.1 `clock_pllfl_sel_t sim_config_k30d10_t::pllFlSel`

12.22.2.1.0.30.2 `clock_er32k_src_t sim_config_k30d10_t::er32kSrc`

12.22.2.1.0.30.3 `uint8_t sim_config_k30d10_t::outdiv4`

12.22.3 Macro Definition Documentation

12.22.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.22.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.22.3.3 `#define USB_EXT_CLK_COUNT 1`

12.22.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.22.4 Variable Documentation

12.22.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.22.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K40D10

12.23 K40D10

The data structure definition for K40D10 Clock Manager.

12.23.1 Overview

Files

- file [fsl_clock_MK40D10.h](#)

Data Structures

- struct [sim_config_k40d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.23.2 Data Structure Documentation

12.23.2.1 struct [sim_config_k40d10_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.23.2.1.0.31 Field Documentation

12.23.2.1.0.31.1 `clock_pllfl_sel_t sim_config_k40d10_t::pllFlSel`

12.23.2.1.0.31.2 `clock_er32k_src_t sim_config_k40d10_t::er32kSrc`

12.23.2.1.0.31.3 `uint8_t sim_config_k40d10_t::outdiv4`

12.23.3 Macro Definition Documentation

12.23.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.23.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.23.3.3 `#define USB_EXT_CLK_COUNT 1`

12.23.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.23.4 Variable Documentation

12.23.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.23.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K50D10

12.24 K50D10

The data structure definition for K50D10 Clock Manager.

12.24.1 Overview

Files

- file [fsl_clock_MK50D10.h](#)

Data Structures

- struct [sim_config_k50d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.24.2 Data Structure Documentation

12.24.2.1 struct sim_config_k50d10_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.24.2.1.0.32 Field Documentation

12.24.2.1.0.32.1 `clock_pllfl_sel_t sim_config_k50d10_t::pllFlSel`

12.24.2.1.0.32.2 `clock_er32k_src_t sim_config_k50d10_t::er32kSrc`

12.24.2.1.0.32.3 `uint8_t sim_config_k50d10_t::outdiv4`

12.24.3 Macro Definition Documentation

12.24.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.24.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.24.3.3 `#define USB_EXT_CLK_COUNT 1`

12.24.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.24.4 Variable Documentation

12.24.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.24.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K51D10

12.25 K51D10

The data structure definition for K51D10 Clock Manager.

12.25.1 Overview

Files

- file [fsl_clock_MK51D10.h](#)

Data Structures

- struct [sim_config_k51d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.25.2 Data Structure Documentation

12.25.2.1 struct sim_config_k51d10_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.25.2.1.0.33 Field Documentation

12.25.2.1.0.33.1 `clock_pllfl_sel_t sim_config_k51d10_t::pllFlSel`

12.25.2.1.0.33.2 `clock_er32k_src_t sim_config_k51d10_t::er32kSrc`

12.25.2.1.0.33.3 `uint8_t sim_config_k51d10_t::outdiv4`

12.25.3 Macro Definition Documentation

12.25.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.25.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.25.3.3 `#define USB_EXT_CLK_COUNT 1`

12.25.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.25.4 Variable Documentation

12.25.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.25.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K52D10

12.26 K52D10

The data structure definition for K52D10 Clock Manager.

12.26.1 Overview

Files

- file [fsl_clock_MK52D10.h](#)

Data Structures

- struct [sim_config_k52d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.26.2 Data Structure Documentation

12.26.2.1 struct sim_config_k52d10_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.26.2.1.0.34 Field Documentation

12.26.2.1.0.34.1 `clock_pllfl_sel_t sim_config_k52d10_t::pllFlSel`

12.26.2.1.0.34.2 `clock_er32k_src_t sim_config_k52d10_t::er32kSrc`

12.26.2.1.0.34.3 `uint8_t sim_config_k52d10_t::outdiv4`

12.26.3 Macro Definition Documentation

12.26.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.26.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.26.3.3 `#define USB_EXT_CLK_COUNT 1`

12.26.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.26.4 Variable Documentation

12.26.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.26.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K53D10

12.27 K53D10

The data structure definition for K53D10 Clock Manager.

12.27.1 Overview

Files

- file [fsl_clock_MK53D10.h](#)

Data Structures

- struct [sim_config_k53d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency([ENET_1588_CLKIN](#))
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency([SDHC_CLKIN](#)).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency([FTM_CLK](#)).

12.27.2 Data Structure Documentation

12.27.2.1 struct sim_config_k53d10_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.27.2.1.0.35 Field Documentation

12.27.2.1.0.35.1 `clock_pllfl_sel_t sim_config_k53d10_t::pllFlSel`

12.27.2.1.0.35.2 `clock_er32k_src_t sim_config_k53d10_t::er32kSrc`

12.27.2.1.0.35.3 `uint8_t sim_config_k53d10_t::outdiv4`

12.27.3 Macro Definition Documentation

12.27.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.27.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.27.3.3 `#define USB_EXT_CLK_COUNT 1`

12.27.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.27.4 Variable Documentation

12.27.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.27.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K60D10

12.28 K60D10

The data structure definition for K60D10 Clock Manager.

12.28.1 Overview

K60D10 clock manager code is shared by K10D10, K20D10, K30D10, K40D10, K50D10, K51D10, K52D10, K53D10 and K60D10.

Files

- file [fsl_clock_MK60D10.h](#)

Data Structures

- struct [sim_config_k60d10_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency(ENET_1588_CLKIN)
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency(SDHC_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.28.2 Data Structure Documentation

12.28.2.1 struct sim_config_k60d10_t

Data Fields

- [clock_pllfl_sel_t pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t er32kSrc](#)
ERCLK32K source selection.
- [uint8_t outdiv4](#)
OUTDIV setting.

12.28.2.1.0.36 Field Documentation

12.28.2.1.0.36.1 [clock_pllfl_sel_t sim_config_k60d10_t::pllFlSel](#)

12.28.2.1.0.36.2 [clock_er32k_src_t sim_config_k60d10_t::er32kSrc](#)

12.28.2.1.0.36.3 [uint8_t sim_config_k60d10_t::outdiv4](#)

12.28.3 Macro Definition Documentation

12.28.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.28.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.28.3.3 `#define USB_EXT_CLK_COUNT 1`

12.28.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.28.4 Variable Documentation

12.28.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.28.4.2 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K63F12

12.29 K63F12

The data structure definition for K63F12 Clock Manager.

12.29.1 Overview

Files

- file [fsl_clock_MK63F12.h](#)

Data Structures

- struct [sim_config_k63f12_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [ENET_EXT_CLK_COUNT](#) 1
ENET external clock source count.
- #define [SDHC_EXT_CLK_COUNT](#) 1
SDHC external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_enet1588ClkInFreq](#) [[ENET_EXT_CLK_COUNT](#)]
ENET external clock frequency(ENET_1588_CLKIN)
- uint32_t [g_sdhcClkInFreq](#) [[SDHC_EXT_CLK_COUNT](#)]
SDHC external clock frequency(SDHC_CLKIN).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.29.2 Data Structure Documentation

12.29.2.1 struct sim_config_k63f12_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlISel](#)

- *PLL/FLL/IRC48M selection.*
- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

12.29.2.1.0.37 Field Documentation

12.29.2.1.0.37.1 `clock_pllfl_sel_t sim_config_k63f12_t::pllFlSel`

12.29.2.1.0.37.2 `clock_er32k_src_t sim_config_k63f12_t::er32kSrc`

12.29.2.1.0.37.3 `uint8_t sim_config_k63f12_t::outdiv4`

12.29.3 Macro Definition Documentation

12.29.3.1 `#define ENET_EXT_CLK_COUNT 1`

12.29.3.2 `#define SDHC_EXT_CLK_COUNT 1`

12.29.3.3 `#define USB_EXT_CLK_COUNT 1`

12.29.3.4 `#define FTM_EXT_CLK_COUNT 2`

12.29.4 Variable Documentation

12.29.4.1 `uint32_t g_sdhcClkInFreq[SDHC_EXT_CLK_COUNT]`

12.29.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.29.4.3 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

K64F12

12.30 K64F12

The data structure definition for K64F12 Clock Manager.

12.30.1 Overview

12.30.3.20 #define USB_EXT_CLK_COUNT 1

12.31 KL02Z4

The data structure definition for KL02Z4 Clock Manager.

12.31.1 Overview

Files

- file [fsl_clock_MKL02Z4.h](#)

Data Structures

- struct [sim_config_kl02z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.31.2 Data Structure Documentation

12.31.2.1 struct sim_config_kl02z4_t

Data Fields

- uint8_t [outdiv4](#)
OUTDIV setting.

KL02Z4

12.31.2.1.0.45 Field Documentation

12.31.2.1.0.45.1 uint8_t sim_config_kl02z4_t::outdiv4

12.31.3 Macro Definition Documentation

12.31.3.1 #define TPM_EXT_CLK_COUNT 2

12.31.4 Variable Documentation

12.31.4.1 uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]

12.32 KL03Z4

The data structure definition for KL03Z4 Clock Manager.

12.32.1 Overview

Files

- file [fsl_clock_MKL03Z4.h](#)

Data Structures

- struct [sim_config_kl03z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.32.2 Data Structure Documentation

12.32.2.1 struct [sim_config_kl03z4_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL03Z4

12.32.2.1.0.46 Field Documentation

12.32.2.1.0.46.1 `clock_er32k_src_t sim_config_kl03z4_t::er32kSrc`

12.32.2.1.0.46.2 `uint8_t sim_config_kl03z4_t::outdiv4`

12.32.3 Macro Definition Documentation

12.32.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.32.4 Variable Documentation

12.32.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.33 KL127Z644

The data structure definition for KL127Z644 Clock Manager.

12.33.1 Overview

Files

- file [fsl_clock_MKL27Z644.h](#)

Data Structures

- struct [sim_config_kl27z644_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.33.2 Data Structure Documentation

12.33.2.1 struct sim_config_kl27z644_t

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL127Z644

12.33.2.1.0.47 Field Documentation

12.33.2.1.0.47.1 `clock_er32k_src_t sim_config_kl27z644_t::er32kSrc`

12.33.2.1.0.47.2 `uint8_t sim_config_kl27z644_t::outdiv4`

12.33.3 Macro Definition Documentation

12.33.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.33.3.2 `#define USB_EXT_CLK_COUNT 1`

12.33.4 Variable Documentation

12.33.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.33.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.34 KL13Z644

The data structure definition for KL13Z644 Clock Manager.

12.34.1 Overview

Files

- file [fsl_clock_MKL13Z644.h](#)

Data Structures

- struct [sim_config_kl13z644_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.34.2 Data Structure Documentation

12.34.2.1 struct [sim_config_kl13z644_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL13Z644

12.34.2.1.0.48 Field Documentation

12.34.2.1.0.48.1 `clock_er32k_src_t sim_config_kl13z644_t::er32kSrc`

12.34.2.1.0.48.2 `uint8_t sim_config_kl13z644_t::outdiv4`

12.34.3 Macro Definition Documentation

12.34.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.34.4 Variable Documentation

12.34.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.35 KL14Z4

The data structure definition for KL14Z4 Clock Manager.

12.35.1 Overview

Files

- file [fsl_clock_MKL14Z4.h](#)

Data Structures

- struct [sim_config_kl14z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.35.2 Data Structure Documentation

12.35.2.1 struct sim_config_kl14z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL14Z4

12.35.2.1.0.49 Field Documentation

12.35.2.1.0.49.1 `clock_pllfl_sel_t sim_config_kl14z4_t::pllFlSel`

12.35.2.1.0.49.2 `clock_er32k_src_t sim_config_kl14z4_t::er32kSrc`

12.35.2.1.0.49.3 `uint8_t sim_config_kl14z4_t::outdiv4`

12.35.3 Macro Definition Documentation

12.35.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.35.3.2 `#define USB_EXT_CLK_COUNT 1`

12.35.4 Variable Documentation

12.35.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.35.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.36 KL15Z4

The data structure definition for KL15Z4 Clock Manager.

12.36.1 Overview

Files

- file [fsl_clock_MKL15Z4.h](#)

Data Structures

- struct [sim_config_kl15z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.36.2 Data Structure Documentation

12.36.2.1 struct sim_config_kl15z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL15Z4

12.36.2.1.0.50 Field Documentation

12.36.2.1.0.50.1 `clock_pllfl_sel_t sim_config_kl15z4_t::pllFlSel`

12.36.2.1.0.50.2 `clock_er32k_src_t sim_config_kl15z4_t::er32kSrc`

12.36.2.1.0.50.3 `uint8_t sim_config_kl15z4_t::outdiv4`

12.36.3 Macro Definition Documentation

12.36.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.36.3.2 `#define USB_EXT_CLK_COUNT 1`

12.36.4 Variable Documentation

12.36.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.36.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.37 KL16Z4

The data structure definition for KL16Z4 Clock Manager.

12.37.1 Overview

Files

- file [fsl_clock_MKL16Z4.h](#)

Data Structures

- struct [sim_config_kl16z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.37.2 Data Structure Documentation

12.37.2.1 struct sim_config_kl16z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL16Z4

12.37.2.1.0.51 Field Documentation

12.37.2.1.0.51.1 `clock_pllfl_sel_t sim_config_kl16z4_t::pllFlSel`

12.37.2.1.0.51.2 `clock_er32k_src_t sim_config_kl16z4_t::er32kSrc`

12.37.2.1.0.51.3 `uint8_t sim_config_kl16z4_t::outdiv4`

12.37.3 Macro Definition Documentation

12.37.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.37.3.2 `#define USB_EXT_CLK_COUNT 1`

12.37.4 Variable Documentation

12.37.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.38 KL17Z4

The data structure definition for KL17Z4 Clock Manager.

12.38.1 Overview

Files

- file [fsl_clock_MKL17Z4.h](#)

Data Structures

- struct [sim_config_kl17z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.38.2 Data Structure Documentation

12.38.2.1 struct sim_config_kl17z4_t

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL17Z4

12.38.2.1.0.52 Field Documentation

12.38.2.1.0.52.1 `clock_er32k_src_t sim_config_kl17z4_t::er32kSrc`

12.38.2.1.0.52.2 `uint8_t sim_config_kl17z4_t::outdiv4`

12.38.3 Macro Definition Documentation

12.38.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.38.3.2 `#define USB_EXT_CLK_COUNT 1`

12.38.4 Variable Documentation

12.38.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.39 KL17Z644

The data structure definition for KL17Z644 Clock Manager.

12.39.1 Overview

Files

- file [fsl_clock_MKL17Z644.h](#)

Data Structures

- struct [sim_config_kl17z644_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.39.2 Data Structure Documentation

12.39.2.1 struct sim_config_kl17z644_t

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL17Z644

12.39.2.1.0.53 Field Documentation

12.39.2.1.0.53.1 `clock_er32k_src_t sim_config_kl17z644_t::er32kSrc`

12.39.2.1.0.53.2 `uint8_t sim_config_kl17z644_t::outdiv4`

12.39.3 Macro Definition Documentation

12.39.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.39.3.2 `#define USB_EXT_CLK_COUNT 1`

12.39.4 Variable Documentation

12.39.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.39.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.40 KL24Z4

The data structure definition for KL24Z4 Clock Manager.

12.40.1 Overview

Files

- file [fsl_clock_MKL24Z4.h](#)

Data Structures

- struct [sim_config_kl24z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.40.2 Data Structure Documentation

12.40.2.1 struct sim_config_kl24z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL24Z4

12.40.2.1.0.54 Field Documentation

12.40.2.1.0.54.1 `clock_pllfl_sel_t sim_config_kl24z4_t::pllFlSel`

12.40.2.1.0.54.2 `clock_er32k_src_t sim_config_kl24z4_t::er32kSrc`

12.40.2.1.0.54.3 `uint8_t sim_config_kl24z4_t::outdiv4`

12.40.3 Macro Definition Documentation

12.40.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.40.3.2 `#define USB_EXT_CLK_COUNT 1`

12.40.4 Variable Documentation

12.40.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.40.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.41 KL25Z4

The data structure definition for KL25Z4 Clock Manager.

12.41.1 Overview

Files

- file [fsl_clock_MKL25Z4.h](#)

Data Structures

- struct [sim_config_kl25z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).

12.41.2 Data Structure Documentation

12.41.2.1 struct sim_config_kl25z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL25Z4

12.41.2.1.0.55 Field Documentation

12.41.2.1.0.55.1 `clock_pllfl_sel_t sim_config_kl25z4_t::pllFlSel`

12.41.2.1.0.55.2 `clock_er32k_src_t sim_config_kl25z4_t::er32kSrc`

12.41.2.1.0.55.3 `uint8_t sim_config_kl25z4_t::outdiv4`

12.41.3 Macro Definition Documentation

12.41.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.41.3.2 `#define USB_EXT_CLK_COUNT 1`

12.41.4 Variable Documentation

12.41.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.41.4.2 `uint32_t g_usbClkInFreq[USB_EXT_CLK_COUNT]`

12.42 KL26Z4

The data structure definition for KL26Z4 Clock Manager.

12.42.1 Overview

Files

- file [fsl_clock_MKL26Z4.h](#)

Data Structures

- struct [sim_config_kl26z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.42.2 Data Structure Documentation

12.42.2.1 struct [sim_config_kl26z4_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL26Z4

12.42.2.1.0.56 Field Documentation

12.42.2.1.0.56.1 `clock_pllfl_sel_t sim_config_kl26z4_t::pllFlSel`

12.42.2.1.0.56.2 `clock_er32k_src_t sim_config_kl26z4_t::er32kSrc`

12.42.2.1.0.56.3 `uint8_t sim_config_kl26z4_t::outdiv4`

12.42.3 Macro Definition Documentation

12.42.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.42.3.2 `#define USB_EXT_CLK_COUNT 1`

12.42.4 Variable Documentation

12.42.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.43 KL27Z4

The data structure definition for KL27Z4 Clock Manager.

12.43.1 Overview

Files

- file [fsl_clock_MKL27Z4.h](#)

Data Structures

- struct [sim_config_kl27z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.43.2 Data Structure Documentation

12.43.2.1 struct sim_config_kl27z4_t

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL27Z4

12.43.2.1.0.57 Field Documentation

12.43.2.1.0.57.1 `clock_er32k_src_t sim_config_kl27z4_t::er32kSrc`

12.43.2.1.0.57.2 `uint8_t sim_config_kl27z4_t::outdiv4`

12.43.3 Macro Definition Documentation

12.43.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.43.3.2 `#define USB_EXT_CLK_COUNT 1`

12.43.4 Variable Documentation

12.43.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.44 KL33Z4

The data structure definition for KL33Z4 Clock Manager.

12.44.1 Overview

Files

- file [fsl_clock_MKL33Z4.h](#)

Data Structures

- struct [sim_config_kl33z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.44.2 Data Structure Documentation

12.44.2.1 struct [sim_config_kl33z4_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL33Z4

12.44.2.1.0.58 Field Documentation

12.44.2.1.0.58.1 `clock_er32k_src_t sim_config_kl33z4_t::er32kSrc`

12.44.2.1.0.58.2 `uint8_t sim_config_kl33z4_t::outdiv4`

12.44.3 Macro Definition Documentation

12.44.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.44.3.2 `#define USB_EXT_CLK_COUNT 1`

12.44.4 Variable Documentation

12.44.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.45 KL33Z644

The data structure definition for KL33Z644 Clock Manager.

12.45.1 Overview

Files

- file [fsl_clock_MKL33Z644.h](#)

Data Structures

- struct [sim_config_kl33z644_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.45.2 Data Structure Documentation

12.45.2.1 struct [sim_config_kl33z644_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL33Z644

12.45.2.1.0.59 Field Documentation

12.45.2.1.0.59.1 `clock_er32k_src_t sim_config_kl33z644_t::er32kSrc`

12.45.2.1.0.59.2 `uint8_t sim_config_kl33z644_t::outdiv4`

12.45.3 Macro Definition Documentation

12.45.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.45.4 Variable Documentation

12.45.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.46 KL34Z4

The data structure definition for KL34Z4 Clock Manager.

12.46.1 Overview

Files

- file [fsl_clock_MKL34Z4.h](#)

Data Structures

- struct [sim_config_kl34z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.46.2 Data Structure Documentation

12.46.2.1 struct sim_config_kl34z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL34Z4

12.46.2.1.0.60 Field Documentation

12.46.2.1.0.60.1 `clock_pllfl_sel_t sim_config_kl34z4_t::pllFlSel`

12.46.2.1.0.60.2 `clock_er32k_src_t sim_config_kl34z4_t::er32kSrc`

12.46.2.1.0.60.3 `uint8_t sim_config_kl34z4_t::outdiv4`

12.46.3 Macro Definition Documentation

12.46.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.46.3.2 `#define USB_EXT_CLK_COUNT 1`

12.46.4 Variable Documentation

12.46.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.47 KL36Z4

The data structure definition for KL36Z4 Clock Manager.

12.47.1 Overview

Files

- file [fsl_clock_MKL36Z4.h](#)

Data Structures

- struct [sim_config_kl36z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.47.2 Data Structure Documentation

12.47.2.1 struct sim_config_kl36z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL36Z4

12.47.2.1.0.61 Field Documentation

12.47.2.1.0.61.1 `clock_pllfl_sel_t sim_config_kl36z4_t::pllFlSel`

12.47.2.1.0.61.2 `clock_er32k_src_t sim_config_kl36z4_t::er32kSrc`

12.47.2.1.0.61.3 `uint8_t sim_config_kl36z4_t::outdiv4`

12.47.3 Macro Definition Documentation

12.47.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.47.3.2 `#define USB_EXT_CLK_COUNT 1`

12.47.4 Variable Documentation

12.47.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.48 KL43Z4

The data structure definition for KL43Z4 Clock Manager.

12.48.1 Overview

KL43Z4 Clock Manager code is shared by KL17Z4, KL27Z4, KL33Z4 and KL43Z4.

Files

- file [fsl_clock_MKL43Z4.h](#)

Data Structures

- struct [sim_config_kl43z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.48.2 Data Structure Documentation

12.48.2.1 struct sim_config_kl43z4_t

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

KL43Z4

12.48.2.1.0.62 Field Documentation

12.48.2.1.0.62.1 `clock_er32k_src_t sim_config_kl43z4_t::er32kSrc`

12.48.2.1.0.62.2 `uint8_t sim_config_kl43z4_t::outdiv4`

12.48.3 Macro Definition Documentation

12.48.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.48.3.2 `#define USB_EXT_CLK_COUNT 1`

12.48.4 Variable Documentation

12.48.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.49 KL46Z4

The data structure definition for KL46Z4 Clock Manager.

12.49.1 Overview

The data structure definition for KW01Z4 Clock Manager.

KL46Z4 Clock Manager code is shared by KL16Z4, KL26Z4, KL36Z4 and KL46Z4.

Files

- file [fsl_clock_MKL46Z4.h](#)
- file [fsl_clock_MKW01Z4.h](#)

Data Structures

- struct [sim_config_kl46z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)
- struct [osc_user_config_kw01z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).
- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

KL46Z4

12.49.2 Data Structure Documentation

12.49.2.1 struct sim_config_kl46z4_t

Data Fields

- [clock_pllfl_sel_t pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t er32kSrc](#)
ERCLK32K source selection.
- [uint8_t outdiv4](#)
OUTDIV setting.

12.49.2.1.0.63 Field Documentation

12.49.2.1.0.63.1 [clock_pllfl_sel_t sim_config_kl46z4_t::pllFlSel](#)

12.49.2.2 struct osc_user_config_kw01z4_t

Data Fields

- [clock_pllfl_sel_t pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t er32kSrc](#)
ERCLK32K source selection.
- [uint8_t outdiv4](#)
OUTDIV setting.

12.49.2.2.0.64 Field Documentation

12.49.2.2.0.64.1 `clock_pllfl_sel_t osc_user_config_kw01z4_t::pllFlSel`

12.49.2.2.0.64.2 `clock_er32k_src_t osc_user_config_kw01z4_t::er32kSrc`

12.49.2.2.0.64.3 `uint8_t osc_user_config_kw01z4_t::outdiv4`

12.49.3 Macro Definition Documentation

12.49.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.49.3.2 `#define USB_EXT_CLK_COUNT 1`

12.49.3.3 `#define TPM_EXT_CLK_COUNT 2`

12.49.3.4 `#define USB_EXT_CLK_COUNT 1`

12.49.4 Variable Documentation

12.49.4.1 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

12.49.4.2 `uint32_t g_tpmClkFreq[TPM_EXT_CLK_COUNT]`

KM34Z7

12.50 KM34Z7

The data structure definition for KM34Z7 Clock Manager.

12.50.1 Overview

Files

- file [fsl_clock_MKM34Z7.h](#)

Data Structures

- struct [sim_config_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [AFE_EXT_CLK_COUNT](#) 1
AFE external clock source count.
- #define [IRTC_OSC_ENABLE_MASK](#) (1U << 0U)
RTC OSC Enable bit in the IRTC_GP register.
- #define [IRTC_OSC_SC2P_MASK](#) (1U << 1U)
Bit in the IRTC_GP register to enable RTC OSC 2pF capacitor.
- #define [IRTC_OSC_SC4P_MASK](#) (1U << 2U)
Bit in the IRTC_GP register to enable RTC OSC 4pF capacitor.
- #define [IRTC_OSC_SC8P_MASK](#) (1U << 3U)
Bit in the IRTC_GP register to enable RTC OSC 8pF capacitor.
- #define [IRTC_OSC_SC16P_MASK](#) (1U << 4U)
Bit in the IRTC_GP register to enable RTC OSC 16pF capacitor.

Functions

- static void [CLOCK_SYS_SetSysDiv](#) (uint8_t sysdiv)
Sets the system clock divider setting(CLKDIVSYS).
- static uint8_t [CLOCK_SYS_GetSysDiv](#) (void)
Gets the system clock divider setting(CLKDIVSYS).
- static void [CLOCK_SYS_SetBusDiv](#) (uint8_t busdiv)
Sets the bus clock divider setting(CLKDIVBUS).
- static uint8_t [CLOCK_SYS_GetBusDiv](#) (void)
Gets the bus clock divider setting(CLKDIVBUS).
- static void [CLOCK_SYS_SetFlashClockMode](#) (uint8_t flashclkmode)
Sets the flash clock mode setting(FLASHCLKMODE).
- static uint8_t [CLOCK_SYS_GetFlashClkMode](#) (void)
Gets the flash clock divider setting(FLASHCLKMODE).
- static uint32_t [CLOCK_SYS_GetFixedFreqClockFreq](#) (void)

- Gets the MCGFFCLK clock frequency.*

 - static uint32_t **CLOCK_SYS_GetInternalRefClockFreq** (void)
- Get internal reference clock frequency.*

 - uint32_t **CLOCK_SYS_GetExternalRefClock32kFreq** (void)
- Gets the external reference 32k clock frequency.*

 - static void **CLOCK_SYS_SetExternalRefClock32kSrc** (clock_er32k_src_t src)
- Set the clock selection of ERCLK32K.*

 - static clock_er32k_src_t **CLOCK_SYS_GetExternalRefClock32kSrc** (void)
- Get the clock selection of ERCLK32K.*

 - uint32_t **CLOCK_SYS_GetOsc0ExternalRefClockFreq** (void)
- Gets the OSC0ERCLK frequency.*

 - uint32_t **CLOCK_SYS_GetRtcOutFreq** (void)
- Gets RTC_CLK frequency.*

 - static void **CLOCK_SYS_SetRtcOutSrc** (clock_rtcout_src_t src)
- Gets RTC_CLK source.*

 - static clock_rtcout_src_t **CLOCK_SYS_GetRtcOutSrc** (void)
- Gets RTC_CLK source.*

 - uint32_t **CLOCK_SYS_GetAfeFreq** (uint32_t instance, clock_afe_src_t afeSrc)
- Gets the AFE module clock frequency.*

 - uint32_t **CLOCK_SYS_GetWdogFreq** (uint32_t instance, clock_wdog_src_t wdogSrc)
- Gets the watch dog clock frequency.*

 - uint32_t **CLOCK_SYS_GetLptmrFreq** (uint32_t instance, clock_lptmr_src_t lptmrSrc)
- Gets LPTMRx pre-scaler/glitch filter clock frequency.*

 - uint32_t **CLOCK_SYS_GetSlcdFreq** (uint32_t instance, clock_slcd_src_t slcdSrc)
- Gets the Segment LCD clock frequency.*

 - uint32_t **CLOCK_SYS_GetUartFreq** (uint32_t instance)
- Gets the clock frequency for UART module.*

 - static uint32_t **CLOCK_SYS_GetAdcAltFreq** (uint32_t instance)
- Gets ADC alternate clock frequency.*

 - static uint32_t **CLOCK_SYS_GetGpioFreq** (uint32_t instance)
- Gets the clock frequency for GPIO module.*

 - static uint32_t **CLOCK_SYS_GetEwmFreq** (uint32_t instance)
- Gets the clock frequency for EWM module.*

 - static uint32_t **CLOCK_SYS_GetPdbFreq** (uint32_t instance)
- Gets the clock frequency for PDB module.*

 - static uint32_t **CLOCK_SYS_GetCrcFreq** (uint32_t instance)
- Gets the clock frequency for CRC module.*

 - static uint32_t **CLOCK_SYS_GetSpiFreq** (uint32_t instance)
- Gets the clock frequency for SPI module.*

 - static uint32_t **CLOCK_SYS_GetI2cFreq** (uint32_t instance)
- Gets the clock frequency for I2C module.*

 - static uint32_t **CLOCK_SYS_GetCmpFreq** (uint32_t instance)
- Gets the clock frequency for CMP module.*

 - static uint32_t **CLOCK_SYS_GetPitFreq** (uint32_t instance)
- Gets the clock frequency for PIT module.*

 - static uint32_t **CLOCK_SYS_GetFtfFreq** (uint32_t instance)
- Gets the clock frequency for FTF module.*

 - static void **CLOCK_SYS_EnableDmaClock** (uint32_t instance)
- Enable the clock for DMA module.*

 - static void **CLOCK_SYS_DisableDmaClock** (uint32_t instance)
- Disable the clock for DMA module.*

- static bool [CLOCK_SYS_GetDmaGateCmd](#) (uint32_t instance)
Get the the clock gate state for DMA module.
- static void [CLOCK_SYS_EnableDmamuxClock](#) (uint32_t instance)
Enable the clock for DMAMUX module.
- static void [CLOCK_SYS_DisableDmamuxClock](#) (uint32_t instance)
Disable the clock for DMAMUX module.
- static bool [CLOCK_SYS_GetDmamuxGateCmd](#) (uint32_t instance)
Get the the clock gate state for DMAMUX module.
- void [CLOCK_SYS_EnablePortClock](#) (uint32_t instance)
Enable the clock for PORT module.
- void [CLOCK_SYS_DisablePortClock](#) (uint32_t instance)
Disable the clock for PORT module.
- bool [CLOCK_SYS_GetPortGateCmd](#) (uint32_t instance)
Get the the clock gate state for PORT module.
- static void [CLOCK_SYS_EnableFtfClock](#) (uint32_t instance)
Enable the clock for FTF module.
- static void [CLOCK_SYS_DisableFtfClock](#) (uint32_t instance)
Disable the clock for FTF module.
- static bool [CLOCK_SYS_GetFtfGateCmd](#) (uint32_t instance)
Get the the clock gate state for FTF module.
- void [CLOCK_SYS_EnableAdcClock](#) (uint32_t instance)
Enable the clock for ADC module.
- void [CLOCK_SYS_DisableAdcClock](#) (uint32_t instance)
Disable the clock for ADC module.
- bool [CLOCK_SYS_GetAdcGateCmd](#) (uint32_t instance)
Get the the clock gate state for ADC module.
- static void [CLOCK_SYS_EnableCmpClock](#) (uint32_t instance)
Enable the clock for CMP module.
- static void [CLOCK_SYS_DisableCmpClock](#) (uint32_t instance)
Disable the clock for CMP module.
- static bool [CLOCK_SYS_GetCmpGateCmd](#) (uint32_t instance)
Get the the clock gate state for CMP module.
- void [CLOCK_SYS_EnablePitClock](#) (uint32_t instance)
Enable the clock for PIT module.
- void [CLOCK_SYS_DisablePitClock](#) (uint32_t instance)
Disable the clock for PIT module.
- bool [CLOCK_SYS_GetPitGateCmd](#) (uint32_t instance)
Get the the clock gate state for PIT module.
- static void [CLOCK_SYS_EnableLptmrClock](#) (uint32_t instance)
Enable the clock for LPTIMER module.
- static void [CLOCK_SYS_DisableLptmrClock](#) (uint32_t instance)
Disable the clock for LPTIMER module.
- static bool [CLOCK_SYS_GetLptmrGateCmd](#) (uint32_t instance)
Get the the clock gate state for LPTIMER module.
- static void [CLOCK_SYS_EnableRtcClock](#) (uint32_t instance)
Enable the clock for RTC module.
- static void [CLOCK_SYS_DisableRtcClock](#) (uint32_t instance)
Disable the clock for RTC module.
- static bool [CLOCK_SYS_GetRtcGateCmd](#) (uint32_t instance)
Get the the clock gate state for RTC module.
- static void [CLOCK_SYS_EnableRtcRegFileClock](#) (uint32_t instance)

- Enable the clock for RTC_REG_FILE.*

 - static void `CLOCK_SYS_DisableRtcRegFileClock` (uint32_t instance)
- Disable the clock for RTC_REG_FILE.*

 - static bool `CLOCK_SYS_GetRtcRegFileGateCmd` (uint32_t instance)
- Get the the clock gate state for RTC_REG_FILE.*

 - void `CLOCK_SYS_EnableSpiClock` (uint32_t instance)
- Enable the clock for SPI module.*

 - void `CLOCK_SYS_DisableSpiClock` (uint32_t instance)
- Disable the clock for SPI module.*

 - bool `CLOCK_SYS_GetSpiGateCmd` (uint32_t instance)
- Get the the clock gate state for SPI module.*

 - void `CLOCK_SYS_EnableUartClock` (uint32_t instance)
- Enable the clock for UART module.*

 - void `CLOCK_SYS_DisableUartClock` (uint32_t instance)
- Disable the clock for UART module.*

 - bool `CLOCK_SYS_GetUartGateCmd` (uint32_t instance)
- Get the the clock gate state for UART module.*

 - void `CLOCK_SYS_EnableI2cClock` (uint32_t instance)
- Enable the clock for I2C module.*

 - void `CLOCK_SYS_DisableI2cClock` (uint32_t instance)
- Disable the clock for I2C module.*

 - bool `CLOCK_SYS_GetI2cGateCmd` (uint32_t instance)
- Get the the clock gate state for I2C module.*

 - static void `CLOCK_SYS_EnableMmauClock` (uint32_t instance)
- Enable the clock for MMAU module.*

 - static void `CLOCK_SYS_DisableMmauClock` (uint32_t instance)
- Disable the clock for MMAU module.*

 - static bool `CLOCK_SYS_GetMmauGateCmd` (uint32_t instance)
- Get the the clock gate state for MMAU module.*

 - static void `CLOCK_SYS_EnableCauClock` (uint32_t instance)
- Enable the clock for CAU module.*

 - static void `CLOCK_SYS_DisableCauClock` (uint32_t instance)
- Disable the clock for CAU module.*

 - static bool `CLOCK_SYS_GetCauGateCmd` (uint32_t instance)
- Get the the clock gate state for CAU module.*

 - static void `CLOCK_SYS_EnableMpuClock` (uint32_t instance)
- Enable the clock for MPU module.*

 - static void `CLOCK_SYS_DisableMpuClock` (uint32_t instance)
- Disable the clock for MPU module.*

 - static bool `CLOCK_SYS_GetMpuGateCmd` (uint32_t instance)
- Get the the clock gate state for MPU module.*

 - static void `CLOCK_SYS_EnableAfeClock` (uint32_t instance)
- Enable the clock for AFE module.*

 - static void `CLOCK_SYS_DisableAfeClock` (uint32_t instance)
- Disable the clock for AFE module.*

 - static bool `CLOCK_SYS_GetAfeGateCmd` (uint32_t instance)
- Get the the clock gate state for AFE module.*

 - static void `CLOCK_SYS_EnableXbarClock` (uint32_t instance)
- Enable the clock for XBAR module.*

 - static void `CLOCK_SYS_DisableXbarClock` (uint32_t instance)
- Disable the clock for XBAR module.*

- static bool [CLOCK_SYS_GetXbarGateCmd](#) (uint32_t instance)
Get the the clock gate state for XBAR module.
- void [CLOCK_SYS_EnableQuadTmrClock](#) (uint32_t instance)
Enable the clock for Quad Timer module.
- void [CLOCK_SYS_DisableQuadTmrClock](#) (uint32_t instance)
Disable the clock for Quad Timer module.
- bool [CLOCK_SYS_GetQuadTmrGateCmd](#) (uint32_t instance)
Get the the clock gate state for Quad Timer module.
- static void [CLOCK_SYS_EnableSlcdClock](#) (uint32_t instance)
Enable the clock for SLCD module.
- static void [CLOCK_SYS_DisableSlcdClock](#) (uint32_t instance)
Disable the clock for SLCD module.
- static bool [CLOCK_SYS_GetSlcdGateCmd](#) (uint32_t instance)
Get the the clock gate state for SLCD module.
- static void [CLOCK_SYS_EnableEwmClock](#) (uint32_t instance)
Enable the clock for EWM module.
- static void [CLOCK_SYS_DisableEwmClock](#) (uint32_t instance)
Disable the clock for EWM module.
- static bool [CLOCK_SYS_GetEwmGateCmd](#) (uint32_t instance)
Get the the clock gate state for EWM module.
- static void [CLOCK_SYS_EnableRngaClock](#) (uint32_t instance)
Enable the clock for RNGA module.
- static void [CLOCK_SYS_DisableRngaClock](#) (uint32_t instance)
Disable the clock for RNGA module.
- static bool [CLOCK_SYS_GetRngaGateCmd](#) (uint32_t instance)
Get the the clock gate state for RNGA module.
- static void [CLOCK_SYS_EnableLpuartClock](#) (uint32_t instance)
Enable the clock for LPUART module.
- static void [CLOCK_SYS_DisableLpuartClock](#) (uint32_t instance)
Disable the clock for LPUART module.
- static void [CLOCK_SYS_SetLpuartSrc](#) (uint32_t instance, [clock_lpuart_src_t](#) lpuartSrc)
Sets the clock source for LPUART module.
- static [clock_lpuart_src_t](#) [CLOCK_SYS_GetLpuartSrc](#) (uint32_t instance)
Gets the clock source for LPUART module.
- static bool [CLOCK_SYS_GetLpuartGateCmd](#) (uint32_t instance)
Get the the clock gate state for LPUART module.
- uint32_t [CLOCK_SYS_GetLpuartFreq](#) (uint32_t instance)
Gets the clock frequency for LPUART module.
- uint32_t [CLOCK_SYS_GetPllFllClockFreq](#) (void)
Get the MCGPLLCLK/MCGFLLCLK/BUS/RTC_OSC clock frequency selected by PLLFLL register bit.
- static void [CLOCK_SYS_EnableCrcClock](#) (uint32_t instance)
Enable the clock for CRC module.
- static void [CLOCK_SYS_DisableCrcClock](#) (uint32_t instance)
Disable the clock for CRC module.
- static bool [CLOCK_SYS_GetCrcGateCmd](#) (uint32_t instance)
Get the the clock gate state for CRC module.
- static void [CLOCK_SYS_EnablePdbClock](#) (uint32_t instance)
Enable the clock for PDB module.
- static void [CLOCK_SYS_DisablePdbClock](#) (uint32_t instance)
Disable the clock for PDB module.
- static bool [CLOCK_SYS_GetPdbGateCmd](#) (uint32_t instance)

- *Get the the clock gate state for PDB module.*
- static void [CLOCK_SYS_EnableVrefClock](#) (uint32_t instance)
Enable the clock for VREF module.
- static void [CLOCK_SYS_DisableVrefClock](#) (uint32_t instance)
Disable the clock for VREF module.
- static bool [CLOCK_SYS_GetVrefGateCmd](#) (uint32_t instance)
Get the the clock gate state for VREF module.
- static void [CLOCK_SYS_SetAfeExternalFreq](#) (uint32_t srcInstance, uint32_t freq)
Set the AFE external clock frequency(AFE_CLKx).

Variables

- uint32_t [g_afeClkFreq](#) [[AFE_EXT_CLK_COUNT](#)]
AFE_CLK.

12.50.2 Data Structure Documentation

12.50.2.1 struct sim_config_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlISel](#)
PLL/FLL selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [flashclkmode](#)
CLKDIV setting.
- uint8_t [outdiv4](#)
OUTDIV setting.

KM34Z7

12.50.2.1.0.65 Field Documentation

12.50.2.1.0.65.1 `clock_pllfl_sel_t sim_config_t::pllFlSel`

12.50.2.1.0.65.2 `clock_er32k_src_t sim_config_t::er32kSrc`

12.50.2.1.0.65.3 `uint8_t sim_config_t::flashclkmode`

12.50.2.1.0.65.4 `uint8_t sim_config_t::outdiv4`

12.50.3 Macro Definition Documentation

12.50.3.1 `#define AFE_EXT_CLK_COUNT 1`

12.50.4 Function Documentation

12.50.4.1 `static void CLOCK_SYS_SetSysDiv (uint8_t sysdiv) [inline], [static]`

This function sets divide value CLKDIVSYS.

Parameters

| | |
|---------------|------------------------------|
| <i>sysdiv</i> | system clock divider setting |
|---------------|------------------------------|

12.50.4.2 static uint8_t CLOCK_SYS_GetSysDiv (void) [inline], [static]

This function gets divide value CLKDIVSYS.

Returns

clock divider setting

12.50.4.3 static void CLOCK_SYS_SetBusDiv (uint8_t busdiv) [inline], [static]

This function sets divide value CLKDIVBUS.

Parameters

| | |
|---------------|------------------------------|
| <i>busdiv</i> | system clock divider setting |
|---------------|------------------------------|

12.50.4.4 static uint8_t CLOCK_SYS_GetBusDiv (void) [inline], [static]

This function gets divide value CLKDIVBUS.

Returns

clock divider setting

12.50.4.5 static void CLOCK_SYS_SetFlashClockMode (uint8_t flashclkmode) [inline], [static]

This function sets clock mode value FLASHCLKMODE.

Parameters

| | |
|---------------------|--------------------------|
| <i>flashclkmode</i> | flash clock mode setting |
|---------------------|--------------------------|

12.50.4.6 static uint8_t CLOCK_SYS_GetFlashClkMode (void) [inline], [static]

This function gets divide value FLASHCLKMODE.

Returns

flashclkmode setting

12.50.4.7 static uint32_t CLOCK_SYS_GetFixedFreqClockFreq (void) [inline], [static]

This function gets the MCG fixed frequency clock (MCGFFCLK) frequency.

Returns

Current clock frequency.

12.50.4.8 static uint32_t CLOCK_SYS_GetInternalRefClockFreq (void) [inline], [static]

This function gets the internal reference clock frequency.

Returns

Current clock frequency.

12.50.4.9 uint32_t CLOCK_SYS_GetExternalRefClock32kFreq (void)

This function gets the external reference (ERCLK32K) clock frequency.

Returns

Current frequency.

12.50.4.10 static void CLOCK_SYS_SetExternalRefClock32kSrc (clock_er32k_src_t src) [inline], [static]

This function sets the clock selection of ERCLK32K.

Parameters

| | |
|------------|---------------|
| <i>src</i> | clock source. |
|------------|---------------|

12.50.4.11 **static clock_er32k_src_t CLOCK_SYS_GetExternalRefClock32kSrc (void)** **[inline], [static]**

This function gets the clock selection of ERCLK32K.

Returns

Current selection.

12.50.4.12 **uint32_t CLOCK_SYS_GetOsc0ExternalRefClockFreq (void)**

This function gets the OSC0 external reference frequency.

Returns

Current frequency.

12.50.4.13 **uint32_t CLOCK_SYS_GetRtcOutFreq (void)**

This function gets the frequency of RTC_CLK.

Returns

Current frequency.

12.50.4.14 **static void CLOCK_SYS_SetRtcOutSrc (clock_rtcout_src_t src)** **[inline],** **[static]**

This function sets the source of RTC_CLK.

Parameters

KM34Z7

| | |
|------------|------------------------|
| <i>src</i> | RTC_CLK source to set. |
|------------|------------------------|

12.50.4.15 static clock_rtcout_src_t CLOCK_SYS_GetRtcOutSrc (void) [inline], [static]

This function gets the source of RTC_CLK. It is determined by SIM_MISC_CTL[RTCCLKSEL].

Returns

Current source.

12.50.4.16 uint32_t CLOCK_SYS_GetAfeFreq (uint32_t instance, clock_afe_src_t afeSrc)

This function gets the AFE module clock frequency.

Parameters

| | |
|-----------------|------------------------------------|
| <i>instance</i> | module device instance |
| <i>afeSrc</i> | AFE module clock source selection. |

Returns

Current frequency.

12.50.4.17 uint32_t CLOCK_SYS_GetWdogFreq (uint32_t instance, clock_wdog_src_t wdogSrc)

This function gets the watch dog clock frequency.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | module device instance |
| <i>wdogSrc</i> | watch dog clock source selection, WDOG_STCTRLH[CLKSRC]. |

Returns

Current frequency.

12.50.4.18 uint32_t CLOCK_SYS_GetLptmrFreq (uint32_t *instance*, clock_lptmr_src_t *lptmrSrc*)

This function gets the LPTMRx pre-scaler/glitch filter clock frequency.

Parameters

| | |
|-----------------|--------------------------------|
| <i>instance</i> | module device instance |
| <i>lptmrSrc</i> | LPTMRx clock source selection. |

Returns

Current frequency.

12.50.4.19 uint32_t CLOCK_SYS_GetSlcdFreq (uint32_t *instance*, clock_slcd_src_t *slcdSrc*)

This function gets the Segment LCD clock frequency.

Parameters

| | |
|-----------------|-------------------------------------|
| <i>instance</i> | module device instance |
| <i>slcdSrc</i> | segment lcd clock source selection. |

Returns

Current frequency.

12.50.4.20 uint32_t CLOCK_SYS_GetUartFreq (uint32_t *instance*) [inline]

This function gets the clock frequency for UART module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

Get the UART clock frequency.

This function gets the clock frequency for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

This function gets the UART clock frequency.

Parameters

| | |
|-----------------|--------------|
| <i>instance</i> | IP instance. |
|-----------------|--------------|

Returns

Current frequency.

This function gets the clock frequency for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.21 `static uint32_t CLOCK_SYS_GetAdcAltFreq (uint32_t instance) [inline], [static]`

This function gets the ADC alternate clock frequency.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq Current frequency.

12.50.4.22 static uint32_t CLOCK_SYS_GetGpioFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for GPIO module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.23 static uint32_t CLOCK_SYS_GetEwmFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.24 static uint32_t CLOCK_SYS_GetPdbFreq (uint32_t *instance*) [inline], [static]

This function gets the clock frequency for PDB module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.25 `static uint32_t CLOCK_SYS_GetCrcFreq (uint32_t instance) [inline], [static]`

This function gets the clock frequency for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.26 `static uint32_t CLOCK_SYS_GetSpiFreq (uint32_t instance) [inline], [static]`

This function gets the clock frequency for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.27 `static uint32_t CLOCK_SYS_GetI2cFreq (uint32_t instance) [inline], [static]`

This function gets the clock frequency for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.28 `static uint32_t CLOCK_SYS_GetCmpFreq (uint32_t instance) [inline], [static]`

This function gets the clock frequency for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.29 `static uint32_t CLOCK_SYS_GetPitFreq (uint32_t instance) [inline], [static]`

This function gets the clock frequency for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.30 `static uint32_t CLOCK_SYS_GetFtfFreq (uint32_t instance) [inline], [static]`

(Flash Memory)

This function gets the clock frequency for FTF module. (Flash Memory)

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.31 static void CLOCK_SYS_EnableDmaClock (uint32_t *instance*) [inline], [static]

This function enables the clock for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.32 static void CLOCK_SYS_DisableDmaClock (uint32_t *instance*) [inline], [static]

This function disables the clock for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.33 static bool CLOCK_SYS_GetDmaGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for DMA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.34 static void CLOCK_SYS_EnableDmamuxClock (uint32_t *instance*) [inline], [static]

This function enables the clock for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.35 static void CLOCK_SYS_DisableDmamuxClock (uint32_t *instance*)
[inline], [static]

This function disables the clock for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.36 static bool CLOCK_SYS_GetDmamuxGateCmd (uint32_t *instance*)
[inline], [static]

This function gets the clock gate state for DMAMUX module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.37 void CLOCK_SYS_EnablePortClock (uint32_t *instance*)

This function enables the clock for PORT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.38 void CLOCK_SYS_DisablePortClock (uint32_t *instance*)

This function disables the clock for PORT module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.39 bool CLOCK_SYS_GetPortGateCmd (uint32_t *instance*)

This function gets the clock gate state for PORT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.40 static void CLOCK_SYS_EnableFtfClock (uint32_t *instance*) [inline], [static]

This function enables the clock for FTF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.41 static void CLOCK_SYS_DisableFtfClock (uint32_t *instance*) [inline], [static]

This function disables the clock for FTF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.42 static bool CLOCK_SYS_GetFtfGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for FTF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.43 void CLOCK_SYS_EnableAdcClock (uint32_t *instance*) [inline]

This function enables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.44 void CLOCK_SYS_DisableAdcClock (uint32_t *instance*) [inline]

This function disables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for ADC module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.45 **bool** CLOCK_SYS_GetAdcGateCmd (uint32_t *instance*) [inline]

This function gets the clock gate state for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for ADC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.46 **static void** CLOCK_SYS_EnableCmpClock (uint32_t *instance*) [inline], [static]

This function enables the clock for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.47 static void CLOCK_SYS_DisableCmpClock (uint32_t *instance*) [inline], [static]

This function disables the clock for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.48 static bool CLOCK_SYS_GetCmpGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for CMP module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.49 void CLOCK_SYS_EnablePitClock (uint32_t *instance*)

This function enables the clock for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.50 void CLOCK_SYS_DisablePitClock (uint32_t *instance*)

This function disables the clock for PIT module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.51 bool CLOCK_SYS_GetPitGateCmd (uint32_t *instance*)

This function gets the clock gate state for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for PIT module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.52 static void CLOCK_SYS_EnableLptmrClock (uint32_t *instance*) [inline], [static]

This function enables the clock for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.53 static void CLOCK_SYS_DisableLptmrClock (uint32_t *instance*) [inline], [static]

This function disables the clock for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.54 static bool CLOCK_SYS_GetLptmrGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for LPTIMER module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.55 static void CLOCK_SYS_EnableRtcClock (uint32_t *instance*) [inline], [static]

This function enables the clock for RTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.56 static void CLOCK_SYS_DisableRtcClock (uint32_t *instance*) [inline], [static]

This function disables the clock for RTC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.57 static bool CLOCK_SYS_GetRtcGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for RTC module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.58 static void CLOCK_SYS_EnableRtcRegFileClock (uint32_t *instance*) [inline], [static]

This function enables the clock for RTC_REG_FILE .

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.59 static void CLOCK_SYS_DisableRtcRegFileClock (uint32_t *instance*) [inline], [static]

This function disables the clock for RTC_REG_FILE.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.60 static bool CLOCK_SYS_GetRtcRegFileGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for RTC_REG_FILE.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.61 void CLOCK_SYS_EnableSpiClock (uint32_t *instance*) [inline]

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Enable the clock for USBFS module.

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for USBFS module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Enable the clock for SPI module.

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.62 void CLOCK_SYS_DisableSpiClock (uint32_t *instance*) [inline]

This function disables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for SPI module.

Parameters

KM34Z7

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.63 bool CLOCK_SYS_GetSpiGateCmd (uint32_t *instance*) [inline]

This function gets the clock gate state for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for SPI module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.64 void CLOCK_SYS_EnableUartClock (uint32_t *instance*) [inline]

This function enables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for UART moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.65 void CLOCK_SYS_DisableUartClock (uint32_t *instance*) [inline]

This function disables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for UART moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.66 bool CLOCK_SYS_GetUartGateCmd (uint32_t *instance*) [inline]

This function gets the clock gate state for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

KM34Z7

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for UART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for UART moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.67 void CLOCK_SYS_EnableI2cClock (uint32_t *instance*) [inline]

This function enables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function enables the clock for I2C moudle.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.68 void CLOCK_SYS_DisableI2cClock (uint32_t *instance*) [inline]

This function disables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

This function disables the clock for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.69 bool CLOCK_SYS_GetI2cGateCmd (uint32_t *instance*) [inline]

This function gets the clock gate state for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

KM34Z7

Returns

state true - ungated(Enabled), false - gated (Disabled)

This function will get the clock gate state for I2C module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.70 static void CLOCK_SYS_EnableMmauClock (uint32_t *instance*) [inline], [static]

This function enables the clock for MMAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.71 static void CLOCK_SYS_DisableMmauClock (uint32_t *instance*) [inline], [static]

This function disables the clock for MMAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.72 static bool CLOCK_SYS_GetMmauGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for MMAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.73 static void CLOCK_SYS_EnableCauClock (uint32_t *instance*) [inline], [static]

This function enables the clock for CAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.74 static void CLOCK_SYS_DisableCauClock (uint32_t *instance*) [inline], [static]

This function disables the clock for CAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.75 static bool CLOCK_SYS_GetCauGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for CAU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.76 static void CLOCK_SYS_EnableMpuClock (uint32_t *instance*) [inline], [static]

This function enables the clock for MPU module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.77 static void CLOCK_SYS_DisableMpuClock (uint32_t *instance*) [inline], [static]

This function disables the clock for MPU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.78 static bool CLOCK_SYS_GetMpuGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for MPU module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.79 static void CLOCK_SYS_EnableAfeClock (uint32_t *instance*) [inline], [static]

This function enables the clock for AFE module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.80 static void CLOCK_SYS_DisableAfeClock (uint32_t *instance*) [inline], [static]

This function disables the clock for AFE module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.81 static bool CLOCK_SYS_GetAfeGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for AFE module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.82 static void CLOCK_SYS_EnableXbarClock (uint32_t *instance*) [inline], [static]

This function enables the clock for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.83 static void CLOCK_SYS_DisableXbarClock (uint32_t *instance*) [inline], [static]

This function disables the clock for XBAR module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.84 static bool CLOCK_SYS_GetXbarGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for XBAR module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.85 void CLOCK_SYS_EnableQuadTmrClock (uint32_t *instance*)

This function enables the clock for Quad Timer module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.86 void CLOCK_SYS_DisableQuadTmrClock (uint32_t *instance*)

This function disables the clock for Quad Timer module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.87 bool CLOCK_SYS_GetQuadTmrGateCmd (uint32_t *instance*)

This function gets the clock gate state for Quad Timer module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.88 static void CLOCK_SYS_EnableSlcdClock (uint32_t *instance*) [inline], [static]

This function enables the clock for SLCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.89 static void CLOCK_SYS_DisableSlcdClock (uint32_t *instance*) [inline], [static]

This function disables the clock for SLCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.90 static bool CLOCK_SYS_GetSlcdGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for SLCD module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.91 static void CLOCK_SYS_EnableEwmClock (uint32_t *instance*) [inline], [static]

This function enables the clock for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.92 static void CLOCK_SYS_DisableEwmClock (uint32_t *instance*) [inline], [static]

This function disables the clock for EWM module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.93 static bool CLOCK_SYS_GetEwmGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for EWM module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.94 static void CLOCK_SYS_EnableRngaClock (uint32_t *instance*) [inline], [static]

This function enables the clock for RNGA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.95 static void CLOCK_SYS_DisableRngaClock (uint32_t *instance*) [inline], [static]

This function disables the clock for RNGA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.96 static bool CLOCK_SYS_GetRngaGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for RNGA module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.97 static void CLOCK_SYS_EnableLpuartClock (uint32_t *instance*) [inline], [static]

This function enables the clock for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.98 static void CLOCK_SYS_DisableLpuartClock (uint32_t *instance*) [inline], [static]

This function disables the clock for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.99 static void CLOCK_SYS_SetLpuartSrc (uint32_t *instance*, clock_lpuart_src_t *lpuartSrc*) [inline], [static]

This function sets the clock source for LPUART module.

Parameters

| | |
|------------------|------------------------|
| <i>instance</i> | module device instance |
| <i>lpuartSrc</i> | Clock source. |

12.50.4.100 static clock_lpuart_src_t CLOCK_SYS_GetLpuartSrc (uint32_t *instance*) [inline], [static]

This function gets the clock source for LPUART module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

**12.50.4.101 static bool CLOCK_SYS_GetLpuartGateCmd (uint32_t *instance*)
[inline], [static]**

This function gets the clock gate state for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.102 uint32_t CLOCK_SYS_GetLpuartFreq (uint32_t *instance*)

This function gets the clock frequency for LPUART module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

freq clock frequency for this module

12.50.4.103 uint32_t CLOCK_SYS_GetPIIFllClockFreq (void)

This function gets the frequency of the MCGPLLCLK/MCGFLLCLK/BUS/RTC_OSC.

Returns

Current clock frequency.

**12.50.4.104 static void CLOCK_SYS_EnableCrcClock (uint32_t *instance*) [inline],
[static]**

This function enables the clock for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.105 static void CLOCK_SYS_DisableCrcClock (uint32_t *instance*) [inline], [static]

This function disables the clock for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.106 static bool CLOCK_SYS_GetCrcGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for CRC module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.107 static void CLOCK_SYS_EnablePdbClock (uint32_t *instance*) [inline], [static]

This function enables the clock for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.108 static void CLOCK_SYS_DisablePdbClock (uint32_t *instance*) [inline], [static]

This function disables the clock for PDB module.

KM34Z7

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.109 static bool CLOCK_SYS_GetPdbGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for PDB module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.110 static void CLOCK_SYS_EnableVrefClock (uint32_t *instance*) [inline], [static]

This function enables the clock for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.111 static void CLOCK_SYS_DisableVrefClock (uint32_t *instance*) [inline], [static]

This function disables the clock for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

12.50.4.112 static bool CLOCK_SYS_GetVrefGateCmd (uint32_t *instance*) [inline], [static]

This function gets the clock gate state for VREF module.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | module device instance |
|-----------------|------------------------|

Returns

state true - ungated(Enabled), false - gated (Disabled)

12.50.4.113 static void CLOCK_SYS_SetAfeExternalFreq (uint32_t *srcInstance*, uint32_t *freq*) [inline], [static]

This function sets the AFE external clock frequency (AFE_CLKx).

Parameters

| | |
|--------------------|---------------------------|
| <i>srcInstance</i> | External source instance. |
| <i>freq</i> | Frequency value. |

KV10Z1287

12.51 KV10Z1287

The data structure definition for KV10Z1287 Clock Manager.

12.51.1 Overview

Files

- file [fsl_clock_MKV10Z1287.h](#)

Data Structures

- struct [sim_config_kv10z1287_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 3
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.51.2 Data Structure Documentation

12.51.2.1 struct [sim_config_kv10z1287_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv5](#)
OUTDIV setting.
- bool [outdiv5Enable](#)
OUTDIV5EN.

12.51.2.1.0.66 Field Documentation

12.51.2.1.0.66.1 `clock_er32k_src_t sim_config_kv10z1287_t::er32kSrc`

12.51.2.1.0.66.2 `uint8_t sim_config_kv10z1287_t::outdiv5`

12.51.2.1.0.66.3 `bool sim_config_kv10z1287_t::outdiv5Enable`

12.51.3 Macro Definition Documentation

12.51.3.1 `#define FTM_EXT_CLK_COUNT 3`

12.51.4 Variable Documentation

12.51.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV10Z7

12.52 KV10Z7

The data structure definition for KV10Z7 Clock Manager.

12.52.1 Overview

Files

- file [fsl_clock_MKV10Z7.h](#)

Data Structures

- struct [sim_config_kv10z7_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 3
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.52.2 Data Structure Documentation

12.52.2.1 struct [sim_config_kv10z7_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv5](#)
OUTDIV setting.
- bool [outdiv5Enable](#)
OUTDIV5EN.

12.52.2.1.0.67 Field Documentation

12.52.2.1.0.67.1 `clock_er32k_src_t sim_config_kv10z7_t::er32kSrc`

12.52.2.1.0.67.2 `uint8_t sim_config_kv10z7_t::outdiv5`

12.52.2.1.0.67.3 `bool sim_config_kv10z7_t::outdiv5Enable`

12.52.3 Macro Definition Documentation

12.52.3.1 `#define FTM_EXT_CLK_COUNT 3`

12.52.4 Variable Documentation

12.52.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV11Z7

12.53 KV11Z7

The data structure definition for KV11Z7 Clock Manager.

12.53.1 Overview

Files

- file [fsl_clock_MKV11Z7.h](#)

Data Structures

- struct [sim_config_kv11z7_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 3
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.53.2 Data Structure Documentation

12.53.2.1 struct [sim_config_kv11z7_t](#)

Data Fields

- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv5](#)
OUTDIV setting.
- bool [outdiv5Enable](#)
OUTDIV5EN.

12.53.2.1.0.68 Field Documentation

12.53.2.1.0.68.1 `clock_er32k_src_t sim_config_kv11z7_t::er32kSrc`

12.53.2.1.0.68.2 `uint8_t sim_config_kv11z7_t::outdiv5`

12.53.2.1.0.68.3 `bool sim_config_kv11z7_t::outdiv5Enable`

12.53.3 Macro Definition Documentation

12.53.3.1 `#define FTM_EXT_CLK_COUNT 3`

12.53.4 Variable Documentation

12.53.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV30F12810

12.54 KV30F12810

The data structure definition for KV30F12810 Clock Manager.

12.54.1 Overview

Files

- file [fsl_clock_MKV30F12810.h](#)

Data Structures

- struct [sim_config_kv30f12810_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.54.2 Data Structure Documentation

12.54.2.1 struct [sim_config_kv30f12810_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.54.2.1.0.69 Field Documentation

12.54.2.1.0.69.1 `clock_pllfl_sel_t sim_config_kv30f12810_t::pllFlSel`

12.54.2.1.0.69.2 `clock_er32k_src_t sim_config_kv30f12810_t::er32kSrc`

12.54.2.1.0.69.3 `uint8_t sim_config_kv30f12810_t::outdiv4`

12.54.3 Macro Definition Documentation

12.54.3.1 `#define FTM_EXT_CLK_COUNT 2`

12.54.4 Variable Documentation

12.54.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV31F12810

12.55 KV31F12810

The data structure definition for KV31F12810 Clock Manager.

12.55.1 Overview

Files

- file [fsl_clock_MKV31F12810.h](#)

Data Structures

- struct [sim_config_kv31f12810_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.55.2 Data Structure Documentation

12.55.2.1 struct [sim_config_kv31f12810_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.55.2.1.0.70 Field Documentation

12.55.2.1.0.70.1 `clock_pllfl_sel_t sim_config_kv31f12810_t::pllFlSel`

12.55.2.1.0.70.2 `clock_er32k_src_t sim_config_kv31f12810_t::er32kSrc`

12.55.2.1.0.70.3 `uint8_t sim_config_kv31f12810_t::outdiv4`

12.55.3 Macro Definition Documentation

12.55.3.1 `#define FTM_EXT_CLK_COUNT 2`

12.55.4 Variable Documentation

12.55.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV31F25612

12.56 KV31F25612

The data structure definition for KV31F25612 Clock Manager.

12.56.1 Overview

Files

- file [fsl_clock_MKV31F25612.h](#)

Data Structures

- struct [sim_config_kv31f25612_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.56.2 Data Structure Documentation

12.56.2.1 struct [sim_config_kv31f25612_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.56.2.1.0.71 Field Documentation

12.56.2.1.0.71.1 `clock_pllfl_sel_t sim_config_kv31f25612_t::pllFlSel`

12.56.2.1.0.71.2 `clock_er32k_src_t sim_config_kv31f25612_t::er32kSrc`

12.56.2.1.0.71.3 `uint8_t sim_config_kv31f25612_t::outdiv4`

12.56.3 Macro Definition Documentation

12.56.3.1 `#define FTM_EXT_CLK_COUNT 2`

12.56.4 Variable Documentation

12.56.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KV31F51212

12.57 KV31F51212

The data structure definition for KV31F51212 Clock Manager.

12.57.1 Overview

Files

- file [fsl_clock_MKV31F51212.h](#)

Data Structures

- struct [sim_config_kv31f51212_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.

Variables

- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.57.2 Data Structure Documentation

12.57.2.1 struct [sim_config_kv31f51212_t](#)

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.57.2.1.0.72 Field Documentation

12.57.2.1.0.72.1 `clock_pllfl_sel_t sim_config_kv31f51212_t::pllFlSel`

12.57.2.1.0.72.2 `clock_er32k_src_t sim_config_kv31f51212_t::er32kSrc`

12.57.2.1.0.72.3 `uint8_t sim_config_kv31f51212_t::outdiv4`

12.57.3 Macro Definition Documentation

12.57.3.1 `#define FTM_EXT_CLK_COUNT 2`

12.57.4 Variable Documentation

12.57.4.1 `uint32_t g_ftmClkFreq[FTM_EXT_CLK_COUNT]`

KW20Z4

12.58 KW20Z4

The data structure definition for KW20Z4 Clock Manager.

12.58.1 Overview

Files

- file [fsl_clock_MKW20Z4.h](#)

Data Structures

- struct [sim_config_kw20z4_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [TPM_EXT_CLK_COUNT](#) 2
TPM external clock source count.
- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.

Variables

- uint32_t [g_tpmClkFreq](#) [[TPM_EXT_CLK_COUNT](#)]
TPM external clock frequency(TPM_CLK).

12.58.2 Data Structure Documentation

12.58.2.1 struct sim_config_kw20z4_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.
- [clock_er32k_src_t](#) [er32kSrc](#)
ERCLK32K source selection.
- uint8_t [outdiv4](#)
OUTDIV setting.

12.58.2.1.0.73 Field Documentation

12.58.2.1.0.73.1 `clock_pllfl_sel_t sim_config_kw20z4_t::pllFlSel`

12.58.2.1.0.73.2 `clock_er32k_src_t sim_config_kw20z4_t::er32kSrc`

12.58.2.1.0.73.3 `uint8_t sim_config_kw20z4_t::outdiv4`

12.58.3 Macro Definition Documentation

12.58.3.1 `#define TPM_EXT_CLK_COUNT 2`

12.58.3.2 `#define USB_EXT_CLK_COUNT 1`

KW21D5

12.59 KW21D5

The data structure definition for KW21D5 Clock Manager.

12.59.1 Overview

Files

- file [fsl_clock_MKW21D5.h](#)

Data Structures

- struct [sim_config_kw21d5_t](#)
SIM configuration structure for dynamic clock setting. [More...](#)

Macros

- #define [USB_EXT_CLK_COUNT](#) 1
USB external clock source count.
- #define [FTM_EXT_CLK_COUNT](#) 2
FTM external clock source count.
- #define [CLOCK_CONFIG_NUM](#) 2
Default clock configuration number.
- #define [CLOCK_CONFIG_INDEX_FOR_VLPR](#) 0
Clock configuration index for VLPR mode.
- #define [CLOCK_CONFIG_INDEX_FOR_RUN](#) 1
Clock configuration index for RUN mode.

Variables

- uint32_t [g_usbClkInFreq](#) [[USB_EXT_CLK_COUNT](#)]
USB external clock frequency(USB_CLKIN).
- uint32_t [g_ftmClkFreq](#) [[FTM_EXT_CLK_COUNT](#)]
FTM external clock frequency(FTM_CLK).

12.59.2 Data Structure Documentation

12.59.2.1 struct sim_config_kw21d5_t

Data Fields

- [clock_pllfl_sel_t](#) [pllFlSel](#)
PLL/FLL/IRC48M selection.

- `clock_er32k_src_t er32kSrc`
ERCLK32K source selection.
- `uint8_t outdiv4`
OUTDIV setting.

Chapter 13

Digital-to-Analog Converter (DAC)

13.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Digital-to-Analog Converter block of Kinetis devices.

Modules

- [DAC HAL Driver](#)
- [DAC Peripheral Driver](#)

DAC HAL Driver

13.2 DAC HAL Driver

13.2.1 Overview

This section describes the programming interface of the DAC HAL driver.

Data Structures

- struct `dac_converter_config_t`
Defines the type of structure for configuring the DAC converter. [More...](#)
- struct `dac_buffer_config_t`
Defines the type of structure for configuring the DAC buffer. [More...](#)

Enumerations

- enum `dac_status_t` {
`kStatus_DAC_Success` = 0U,
`kStatus_DAC_InvalidArgument` = 1U,
`kStatus_DAC_Failed` = 2U }
DAC status return codes.
- enum `dac_ref_volt_src_mode_t` {
`kDacRefVoltSrcOfVref1` = 0U,
`kDacRefVoltSrcOfVref2` = 1U }
Defines the type of selection for DAC module's reference voltage source.
- enum `dac_trigger_mode_t` {
`kDacTriggerByHardware` = 0U,
`kDacTriggerBySoftware` = 1U }
Defines the type of selection for DAC module trigger mode.
- enum `dac_buff_watermark_mode_t` {
`kDacBuffWatermarkFromUpperAs1Word` = 0U,
`kDacBuffWatermarkFromUpperAs2Word` = 1U,
`kDacBuffWatermarkFromUpperAs3Word` = 2U,
`kDacBuffWatermarkFromUpperAs4Word` = 3U }
Defines the type of selection for buffer watermark mode.
- enum `dac_buff_work_mode_t` { `kDacBuffWorkAsNormalMode` = 0U }
Defines the type of selection for buffer work mode.

Functions

- void `DAC_HAL_Init` (DAC_Type *base)
Resets all configurable registers to the reset state for DAC.
- void `DAC_HAL_ConfigConverter` (DAC_Type *base, const `dac_converter_config_t` *configPtr)
Configures the converter for DAC.
- void `DAC_HAL_ConfigBuffer` (DAC_Type *base, const `dac_buffer_config_t` *configPtr)
Configures the buffer for DAC.

- void [DAC_HAL_SetBuffValue](#) (DAC_Type *base, uint8_t idx, uint16_t value)
Sets the 12-bit value for the DAC items in the buffer.
- static void [DAC_HAL_ClearBuffIdxUpperFlag](#) (DAC_Type *base)
Clears the flag of the DAC buffer read pointer.
- static bool [DAC_HAL_GetBuffIdxUpperFlag](#) (DAC_Type *base)
Gets the flag of the DAC buffer read pointer when it reaches the bottom position.
- static void [DAC_HAL_ClearBuffIdxStartFlag](#) (DAC_Type *base)
Clears the flag of the DAC buffer read pointer when it reaches the top position.
- static bool [DAC_HAL_GetBuffIdxStartFlag](#) (DAC_Type *base)
Gets the flag of the DAC buffer read pointer when it reaches the top position.
- static void [DAC_HAL_Enable](#) (DAC_Type *base)
Enables the Programmable Reference Generator.
- static void [DAC_HAL_Disable](#) (DAC_Type *base)
Disables the Programmable Reference Generator.
- static void [DAC_HAL_SetSoftTriggerCmd](#) (DAC_Type *base)
Triggers the converter with software.
- static void [DAC_HAL_SetBuffCurIdx](#) (DAC_Type *base, uint8_t idx)
Sets the buffer index for the DAC module.
- static uint8_t [DAC_HAL_GetBuffCurIdx](#) (DAC_Type *base)
Gets the buffer index for the DAC module.

13.2.2 Data Structure Documentation

13.2.2.1 struct dac_converter_config_t

Data Fields

- [dac_ref_volt_src_mode_t](#) dacRefVoltSrc
Select the reference voltage source.
- bool [lowPowerEnable](#)
Enable the low power mode.

13.2.2.2 struct dac_buffer_config_t

Data Fields

- bool [bufferEnable](#)
Enable the buffer function.
- [dac_trigger_mode_t](#) triggerMode
Select the trigger mode.
- bool [idxStartIntEnable](#)
Switcher to enable interrupt when buffer index reaches the start (0).
- bool [idxUpperIntEnable](#)
Switcher to enable interrupt when buffer index reaches the upper limit.
- bool [dmaEnable](#)
Switcher to enable DMA request by original interrupts.
- [dac_buff_work_mode_t](#) buffWorkMode
Selection of buffer's work mode.

DAC HAL Driver

- `uint8_t upperIdx`
Setting of the buffer's upper limit, 0-15.

13.2.2.2.0.79 Field Documentation

13.2.2.2.0.79.1 `dac_buff_work_mode_t` `dac_buffer_config_t::buffWorkMode`

See "`dac_buff_work_mode_t`".

13.2.3 Enumeration Type Documentation

13.2.3.1 `enum dac_status_t`

Enumerator

`kStatus_DAC_Success` Success.
`kStatus_DAC_InvalidArgument` Invalid argument.
`kStatus_DAC_Failed` Execution failed.

13.2.3.2 `enum dac_ref_volt_src_mode_t`

See the appropriate SoC Reference Manual for actual connections.

Enumerator

`kDacRefVoltSrcOfVref1` Select DACREF_1 as the reference voltage.
`kDacRefVoltSrcOfVref2` Select DACREF_2 as the reference voltage.

13.2.3.3 `enum dac_trigger_mode_t`

Enumerator

`kDacTriggerByHardware` Select hardware trigger.
`kDacTriggerBySoftware` Select software trigger.

13.2.3.4 `enum dac_buff_watermark_mode_t`

If the buffer feature for DAC module is enabled, a watermark event occurs when the buffer index reaches the watermark.

Enumerator

`kDacBuffWatermarkFromUpperAs1Word` Select 1 word away from the upper limit of buffer.

- kDacBuffWatermarkFromUpperAs2Word* Select 2 word away from the upper limit of buffer.
- kDacBuffWatermarkFromUpperAs3Word* Select 3 word away from the upper limit of buffer.
- kDacBuffWatermarkFromUpperAs4Word* Select 4 word away from the upper limit of buffer.

13.2.3.5 enum dac_buff_work_mode_t

These are the work modes when the DAC buffer is enabled.

- Normal mode - When the buffer index reaches the upper level, it starts (0) on the next trigger.
- Swing mode - When the buffer index reaches the upper level, it goes backward to the start and is reduced one-by-one on the next trigger. When the buffer index reaches the start, it goes backward to the upper level and increases one-by-one on the next trigger.
- One-Time-Scan mode - The buffer index can only be increased on the next trigger. When the buffer index reaches the upper level, it is not updated by the trigger.
- FIFO mode - In FIFO mode, the buffer is organized as a FIFO. For a valid write to any item, the data is put into the FIFO. The written index in buffer should be an even number; otherwise, the write is ignored.

Enumerator

- kDacBuffWorkAsNormalMode* Buffer works normally.

13.2.4 Function Documentation

13.2.4.1 void DAC_HAL_Init (DAC_Type * base)

This function resets all configurable registers to the reset state for DAC. It should be called before configuring the DAC module.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

13.2.4.2 void DAC_HAL_ConfigConverter (DAC_Type * base, const dac_converter_config_t * configPtr)

This function configures the converter for DAC. The features it covers are a one-time setting in the application.

DAC HAL Driver

Parameters

| | |
|------------------|-------------------------------------|
| <i>base</i> | The DAC peripheral base address. |
| <i>configPtr</i> | The pointer to configure structure. |

13.2.4.3 void DAC_HAL_ConfigBuffer (DAC_Type * *base*, const dac_buffer_config_t * *configPtr*)

This function configures the converter for DAC. The features it covers are used for the buffer.

Parameters

| | |
|------------------|-------------------------------------|
| <i>base</i> | The DAC peripheral base address. |
| <i>configPtr</i> | The pointer to configure structure. |

13.2.4.4 void DAC_HAL_SetBuffValue (DAC_Type * *base*, uint8_t *idx*, uint16_t *value*)

This function sets the value assembled by the low 8 bits and high 4 bits of 12-bit DAC item in the buffer.

Parameters

| | |
|--------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
| <i>idx</i> | Buffer index. |
| <i>value</i> | Setting value. |

13.2.4.5 static void DAC_HAL_ClearBuffIdxUpperFlag (DAC_Type * *base*) [inline], [static]

This function clears the flag of the DAC buffer read pointer when it reaches the bottom position.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

13.2.4.6 static bool DAC_HAL_GetBuffIdxUpperFlag (DAC_Type * *base*) [inline], [static]

This function gets the flag of DAC buffer read pointer when it reaches the bottom position.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

Returns

Assertion of indicated event.

13.2.4.7 static void DAC_HAL_ClearBuffIdxStartFlag (DAC_Type * *base*) [inline], [static]

This function clears the flag of the DAC buffer read pointer when it reaches the top position.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

13.2.4.8 static bool DAC_HAL_GetBuffIdxStartFlag (DAC_Type * *base*) [inline], [static]

This function gets the flag of the DAC buffer read pointer when it reaches the top position.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

Returns

Assertion of indicated event.

13.2.4.9 static void DAC_HAL_Enable (DAC_Type * *base*) [inline], [static]

This function enables the Programmable Reference Generator. Then, the DAC system is enabled.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

DAC HAL Driver

13.2.4.10 `static void DAC_HAL_Disable (DAC_Type * base) [inline], [static]`

This function disables the Programmable Reference Generator. Then, the DAC system is disabled.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

13.2.4.11 `static void DAC_HAL_SetSoftTriggerCmd (DAC_Type * base) [inline], [static]`

This function triggers the converter with software. If the DAC software trigger is selected and buffer enabled, calling this API advances the buffer read pointer once.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The DAC peripheral base address. |
|-------------|----------------------------------|

13.2.4.12 `static void DAC_HAL_SetBuffCurIdx (DAC_Type * base, uint8_t idx) [inline], [static]`

This function sets the current buffer index for the DAC module.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | the DAC peripheral base address. |
| <i>idx</i> | Setting buffer index. |

13.2.4.13 `static uint8_t DAC_HAL_GetBuffCurIdx (DAC_Type * base) [inline], [static]`

This function gets the current buffer index for the DAC module.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | the DAC peripheral base address. |
|-------------|----------------------------------|

Returns

Current index of buffer.

DAC Peripheral Driver

13.3 DAC Peripheral Driver

13.3.1 Overview

This section describes the programming interface of the DAC Peripheral driver. The DAC peripheral driver configures the DAC (Digital-to-Analog Converter). It also handles the module initialization and configuration by converting attributes.

13.3.2 DAC Initialization

To initialize the DAC module, call the `DAC_DRV_Init()` function and pass the configuration data structure, which can be filled by the `DAC_DRV_StructInitUserConfigNormal()` function with the default settings for the converter. After it is initialized, the DAC module can function as a DAC converter.

The DAC module provides advanced features internally with the hardware buffer. To use the advanced features, the API of the `DAC_DRV_ConfigBuffer()` function should be called to initialize the buffer.

13.3.3 DAC Model building

The DAC module provides advanced features with the hardware DAC buffer.

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in `DAT0`, the first item in the buffer, to analog output voltage. If the buffer is enabled, the DAC converts the items in the data buffer to analog output voltage according to the buffer configuration. The data buffer read pointer advances to the next word whenever any hardware or software trigger event occurs. The data buffer can be configured to operate in Normal mode, Swing mode, One-Time Scan mode or FIFO mode:

- Normal mode is the default mode for the buffer. The buffer works as a FIFO buffer. The read pointer increases once triggered. When the read pointer reaches the upper limit, it goes to zero during the next trigger event.
- Swing mode is similar to the FIFO mode. However, when the read pointer reaches the upper limit, it does not go to zero. It descends by 1 in the next trigger event until it reaches and turns back.
- One-time Scan mode. In One-time Scan mode, the read pointer increases by one, after it is triggered. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it increases to the upper address and stops. If the software sets the read pointer to the upper limit, the read pointer does not advance in this mode. When the buffer operation is switched from one mode to another, the read pointer does not change.
- FIFO mode. In FIFO mode, the buffer works like a ring FIFO. Some configurations are different from other modes. The buffer size is set to the max value by default. The previous upper index is a write pointer of the ring FIFO. The previous read pointer points to the tail of the ring FIFO. When the user pushes the data into FIFO, the write pointer increases. When the user triggers the buffer to pop the data, the read pointer increases.

13.3.4 DAC Call diagram

There are four kinds of typical use cases:

- Normal converter mode. Normal converter mode works without the buffer and the trigger. It is the simplest way to use the DAC module.
- Buffer Normal mode. Buffer Normal mode enables the internal buffer and sets it as a normal ring buffer mode.
- Buffer Swing mode. Buffer Swing mode enables the internal buffer and sets it as a swing mode.
- Buffer One-time Scan mode. One-time Scan buffer mode enables the internal buffer and sets it as a one-time scan mode.
- Buffer FIFO mode. Buffer FIFO enables the internal buffer and sets it as a FIFO mode.

These use cases function either on the software trigger or the hardware trigger. To use the hardware trigger, enable the hardware trigger setting in the DAC module. Then, configure the other module that can generate the trigger, such as the PDB.

These are examples to initialize and configure the DAC driver for typical use cases:

Normal converter mode:

```
// dac_test_normal.c //

#include <stdio.h>
#include <stdint.h>
#include <stdbool.h>
#include "fsl_dac_driver.h"
#include "fsl_os_abstraction.h"

#define DAC_TEST_BUFF_SIZE (16U)

volatile uint32_t g_dacInstance = 0U;

static uint16_t g_dacBuffDat[DAC_TEST_BUFF_SIZE];

extern void DAC_TEST_FillBuffDat(uint16_t *buffPtr, uint32_t buffLen);

void DAC_TEST_NormalMode(uint32_t instance)
{
    dac_user_config_t MyDacUserConfigStruct;
    uint8_t i;

    g_dacInstance = instance;
    // Fill values into data buffer. //
    DAC_TEST_FillBuffDat(g_dacBuffDat, DAC_TEST_BUFF_SIZE);

    // Fill the structure with configuration of software trigger. //

```

Enumerations

- enum `dac_flag_t` {
 - `kDacBuffIndexStartFlag = 1U,`
 - `kDacBuffIndexUpperFlag = 2U }`
 Defines the type of event flags.

Functions

- `dac_status_t DAC_DRV_StructInitUserConfigNormal (dac_converter_config_t *userConfigPtr)`
Populates the initial user configuration for the DAC module without interrupt and buffer features.
- `dac_status_t DAC_DRV_Init (uint32_t instance, const dac_converter_config_t *userConfigPtr)`
Initializes the converter.
- `dac_status_t DAC_DRV_Deinit (uint32_t instance)`
De-initializes the DAC module converter.
- `void DAC_DRV_Output (uint32_t instance, uint16_t value)`
Drives the converter to output the DAC value.
- `dac_status_t DAC_DRV_ConfigBuffer (uint32_t instance, const dac_buffer_config_t *configPtr)`
Configures the internal buffer.
- `dac_status_t DAC_DRV_SetBuffValue (uint32_t instance, uint8_t start, uint8_t offset, uint16_t arr[])`
Sets values into the DAC internal buffer.
- `void DAC_DRV_SoftTriggerBuffCmd (uint32_t instance)`
Triggers the buffer by software and returns the current value.
- `void DAC_DRV_ClearBuffFlag (uint32_t instance, dac_flag_t flag)`
Clears the flag for an indicated event causing an interrupt.
- `bool DAC_DRV_GetBuffFlag (uint32_t instance, dac_flag_t flag)`
Gets the flag for an indicated event causing an interrupt.
- `void DAC_DRV_SetBuffCurIdx (uint32_t instance, uint8_t idx)`
Sets the current read pointer in DAC buffer.
- `uint8_t DAC_DRV_GetBuffCurIdx (uint32_t instance)`

DAC Peripheral Driver

Gets the current read pointer in the DAC buffer.

Variables

- DAC_Type *const [g_dacBase](#) []
Table of base addresses for DAC instances.
- const IRQn_Type [g_dacIrqId](#) [DAC_INSTANCE_COUNT]
Table to save DAC IRQ enumeration numbers defined in the CMSIS header file.

13.3.5 Enumeration Type Documentation

13.3.5.1 enum dac_flag_t

Enumerator

- kDacBuffIndexStartFlag*** Event for the buffer index reaching start (0).
- kDacBuffIndexUpperFlag*** Event for the buffer index reaching the upper chapter.

13.3.6 Function Documentation

13.3.6.1 **dac_status_t DAC_DRV_StructInitUserConfigNormal (dac_converter_config_t * userConfigPtr)**

This function populates the initial user configuration without interrupt and buffer features. Calling the initialization function with the populated parameter configures the DAC module to operate as a simple converter. The settings are:

- .dacRefVoltSrc = kDacRefVoltSrcOfVref2; // Vdda
- .lowPowerEnable = false;

Parameters

| | |
|----------------------|---|
| <i>userConfigPtr</i> | Pointer to the user configuration structure. See the "dac_user_config_t". |
|----------------------|---|

Returns

Execution status.

13.3.6.2 **dac_status_t DAC_DRV_Init (uint32_t instance, const dac_converter_config_t * userConfigPtr)**

This function initializes the converter.

Parameters

| | |
|----------------------|---|
| <i>instance</i> | DAC instance ID. |
| <i>userConfigPtr</i> | Pointer to the initialization structure. See the "dac_user_config_t". |

Returns

Execution status.

13.3.6.3 **dac_status_t DAC_DRV_Deinit (uint32_t *instance*)**

This function de-initializes the converter. It disables the DAC module and shuts down the clock to reduce the power consumption.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | DAC instance ID. |
|-----------------|------------------|

Returns

Execution status.

13.3.6.4 **void DAC_DRV_Output (uint32_t *instance*, uint16_t *value*)**

This function drives the converter to output the DAC value. It forces the buffer index to be the first one and load the setting value to this item. Then, the converter outputs the voltage indicated by the indicated value immediately.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | DAC instance ID. |
| <i>value</i> | Setting value for DAC. |

13.3.6.5 **dac_status_t DAC_DRV_ConfigBuffer (uint32_t *instance*, const dac_buffer_config_t * *configPtr*)**

This function configures the feature of the internal buffer for the DAC module. By default, the buffer feature is disabled. Calling this API enables the buffer and configures it.

DAC Peripheral Driver

Parameters

| | |
|------------------|--|
| <i>instance</i> | DAC instance ID. |
| <i>configPtr</i> | Pointer to the configuration structure. See the "dac_buff_config_t". |

Returns

Execution status.

13.3.6.6 **dac_status_t DAC_DRV_SetBuffValue (uint32_t instance, uint8_t start, uint8_t offset, uint16_t arr[])**

This function sets values into the DAC internal buffer. Note that the buffer size is defined by the "FSL_FEATURE_DAC_BUFFER_SIZE" macro and the available value is 12 bits.

Parameters

| | |
|-----------------|----------------------------------|
| <i>instance</i> | DAC instance ID. |
| <i>start</i> | Start index of setting values. |
| <i>offset</i> | Length of setting values' array. |
| <i>arr</i> | Setting values' array. |

Returns

Execution status.

13.3.6.7 **void DAC_DRV_SoftTriggerBuffCmd (uint32_t instance)**

This function triggers the buffer by software and returns the current value. After it is triggered, the buffer index updates according to work mode. Then, the value kept inside the pointed item is immediately output.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | DAC instance ID. |
|-----------------|------------------|

13.3.6.8 **void DAC_DRV_ClearBuffFlag (uint32_t instance, dac_flag_t flag)**

This function clears the flag for an indicated event causing an interrupt.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | DAC instance ID. |
| <i>flag</i> | Indicated flag. See "dac_flag_t". |

13.3.6.9 bool DAC_DRV_GetBuffFlag (uint32_t *instance*, dac_flag_t *flag*)

This function gets the flag for an indicated event causing an interrupt. If the event occurs, the return value is asserted.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | DAC instance ID. |
| <i>flag</i> | Indicated flag. See "dac_flag_t". |

Returns

Assertion of indicated event.

13.3.6.10 void DAC_DRV_SetBuffCurIdx (uint32_t *instance*, uint8_t *idx*)

This function sets the current read pointer in DAC buffer.

Parameters

| | |
|-----------------|-----------------------------------|
| <i>instance</i> | DAC instance ID. |
| <i>idx</i> | Index for read pointer in buffer. |

13.3.6.11 uint8_t DAC_DRV_GetBuffCurIdx (uint32_t *instance*)

This function gets the current read pointer in DAC buffer.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | DAC instance ID. |
|-----------------|------------------|

Returns

Index for current read pointer in buffer.

DAC Peripheral Driver

13.3.7 Variable Documentation

13.3.7.1 `DAC_Type* const g_dacBase[]`

13.3.7.2 `const IRQn_Type g_dacIrqId[DAC_INSTANCE_COUNT]`

Chapter 14

Utilities for the Kinetis SDK

This part describes the programming interface of the debug console driver.

14.1 Debug Console Initialization

To initialize the DbgConsole module, call the DbgConsole_Init() function and pass in the user configuration structure. This function automatically enables the module and the clock. After the DbgConsole_Init() function is called and returned, stdout and stdin are connected to the selected UART/LPUART.

Pass a user configuration debug_console_device_type_t shown here:

Debug console state is stored in debug_console_state_t structure:

This example shows how to call the DbgConsole_Init() given the user configuration structure and the instance number.

```
DbgConsole_Init(BOARD_DEBUG_UART_INSTANCE, BOARD_DEBUG_UART_BAUD, kDebugConsoleUART);
```

Debug Console formatted IO

Debug console has its own printf/scanf/putchar/getchar functions which are defined in the header:

```
int debug_printf(const char *fmt_s, ...);
int debug_putchar(int ch);
int debug_scanf(const char *fmt_ptr, ...);
int debug_getchar(void);
```

Choose toolchain's printf/scanf or the KSDK version printf/scanf:

```
#if (defined (FSL_RTOS_MQX) && (MQX_COMMON_CONFIG != MQX_LITE_CONFIG))
#define PRINTF          printf
#define SCANF           scanf
#define PUTCHAR        putchar
#define GETCHAR        getchar
#else
/*Configuration for toolchain's printf/scanf or KSDK version printf/scanf
#define PRINTF          debug_printf
//#define PRINTF        printf
#define SCANF           debug_scanf
//#define SCANF         scanf
#define PUTCHAR        debug_putchar
//#define PUTCHAR       putchar
#define GETCHAR        debug_getchar
//#define GETCHAR       getchar
#endif
```

Debug Console Initialization

Print out failure messages using KSDK's `assert_func`:

```
void assert_func(const char *file, int line, const char *func, const char *failedExpr)
{
    PRINTF("ASSERT ERROR \" %s \": file \"%s\" Line \"%d\" function name \"%s\" \n", failedExpr, file ,
        line, func);

    for (;;)
    {}
}
```

Function `_doprint` outputs its parameters according to a formatted string. I/O is performed by calling a given function pointer using `(*func_ptr)(c,farg)`.

```
int _doprint(void *farg, PUTCHAR_FUNC func_ptr, int max_count, char *fmt, va_list ap)
```

Function `scan_prv` converts an input line of ASCII characters based on a provided string format.

```
int scan_prv(const char *line_ptr, char *format, va_list args_ptr)
```

Function `mknumstr` converts a radix number to a string and returns its length.

```
static int32_t mknumstr (char *numstr, void *nump, int32_t neg, int32_t radix, bool use_caps);
```

Function `mkfloatnumstr` converts a floating radix number to a string and returns its length.

```
static int32_t mkfloatnumstr (char *numstr, void *nump, int32_t radix, uint32_t precision_width);
```

Chapter 15

Direct Memory Access (DMA)

15.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Direct Memory Access block of Kinetis devices.

Modules

- [DMA HAL driver](#)
- [DMA driver](#)
- [DMA request](#)
- [DMAMUX HAL driver](#)

DMA HAL driver

15.2 DMA HAL driver

15.2.1 Overview

This section describes the programming interface of the DMA HAL driver.

Data Structures

- struct [dma_channel_link_config_t](#)
Data structure for data structure configuration. [More...](#)
- struct [dma_error_status_t](#)
Data structure to get status of the DMA channel status. [More...](#)

Enumerations

- enum [dma_status_t](#) { ,
[kStatus_DMA_InvalidArgument](#) = 1U,
[kStatus_DMA_Fail](#) = 2U }
DMA status.
- enum [dma_transfer_size_t](#) {
[kDmaTransfersize32bits](#) = 0x0U,
[kDmaTransfersize8bits](#) = 0x1U,
[kDmaTransfersize16bits](#) = 0x2U }
DMA transfer size type.
- enum [dma_modulo_t](#)
Configuration type for the DMA modulo.
- enum [dma_channel_link_type_t](#) {
[kDmaChannelLinkDisable](#) = 0x0U,
[kDmaChannelLinkChan1AndChan2](#) = 0x1U,
[kDmaChannelLinkChan1](#) = 0x2U,
[kDmaChannelLinkChan1AfterBCRO](#) = 0x3U }
DMA channel link type.
- enum [dma_transfer_type_t](#) {
[kDmaPeripheralToMemory](#),
[kDmaMemoryToPeripheral](#),
[kDmaMemoryToMemory](#),
[kDmaPeripheralToPeripheral](#) }
Type for DMA transfer.

DMA HAL channel configuration

- void [DMA_HAL_Init](#) (DMA_Type *base, uint32_t channel)
Sets all registers of the channel to 0.
- void [DMA_HAL_ConfigTransfer](#) (DMA_Type *base, uint32_t channel, [dma_transfer_size_t](#) size, [dma_transfer_type_t](#) type, uint32_t sourceAddr, uint32_t destAddr, uint32_t length)

- Basic DMA transfer configuration.*

 - static void [DMA_HAL_SetSourceAddr](#) (DMA_Type *base, uint32_t channel, uint32_t address)
Configures the source address.
 - static void [DMA_HAL_SetDestAddr](#) (DMA_Type *base, uint32_t channel, uint32_t address)
Configures the source address.
 - static void [DMA_HAL_SetTransferCount](#) (DMA_Type *base, uint32_t channel, uint32_t count)
Configures the bytes to be transferred.
 - static uint32_t [DMA_HAL_GetUnfinishedByte](#) (DMA_Type *base, uint32_t channel)
Gets the left bytes not to be transferred.
 - static void [DMA_HAL_SetIntCmd](#) (DMA_Type *base, uint8_t channel, bool enable)
Enables the interrupt for the DMA channel after the work is done.
 - static void [DMA_HAL_SetCycleStealCmd](#) (DMA_Type *base, uint8_t channel, bool enable)
Configures the DMA transfer mode to cycle steal or continuous modes.
 - static void [DMA_HAL_SetAutoAlignCmd](#) (DMA_Type *base, uint8_t channel, bool enable)
Configures the auto-align feature.
 - static void [DMA_HAL_SetAsyncDmaRequestCmd](#) (DMA_Type *base, uint8_t channel, bool enable)
Configures the a-sync DMA request feature.
 - static void [DMA_HAL_SetSourceIncrementCmd](#) (DMA_Type *base, uint32_t channel, bool enable)
Enables/disables the source increment.
 - static void [DMA_HAL_SetDestIncrementCmd](#) (DMA_Type *base, uint32_t channel, bool enable)
Enables/disables destination increment.
 - static void [DMA_HAL_SetSourceTransferSize](#) (DMA_Type *base, uint32_t channel, [dma_transfer_size_t](#) transfersize)
Configures the source transfer size.
 - static void [DMA_HAL_SetDestTransferSize](#) (DMA_Type *base, uint32_t channel, [dma_transfer_size_t](#) transfersize)
Configures the destination transfer size.
 - static void [DMA_HAL_SetTriggerStartCmd](#) (DMA_Type *base, uint32_t channel, bool enable)
Triggers the start.
 - static void [DMA_HAL_SetSourceModulo](#) (DMA_Type *base, uint32_t channel, [dma_modulo_t](#) modulo)
Configures the modulo for the source address.
 - static void [DMA_HAL_SetDestModulo](#) (DMA_Type *base, uint32_t channel, [dma_modulo_t](#) modulo)
Configures the modulo for the destination address.
 - static void [DMA_HAL_SetDmaRequestCmd](#) (DMA_Type *base, uint32_t channel, bool enable)
Enables/disables the DMA request.
 - static void [DMA_HAL_SetDisableRequestAfterDoneCmd](#) (DMA_Type *base, uint32_t channel, bool enable)
Configures the DMA request state after the work is done.
 - void [DMA_HAL_SetChanLink](#) (DMA_Type *base, uint8_t channel, [dma_channel_link_config_t](#) *mode)
Configures the channel link feature.
 - static void [DMA_HAL_ClearStatus](#) (DMA_Type *base, uint8_t channel)
Clears the status of the DMA channel.
 - [dma_error_status_t](#) [DMA_HAL_GetStatus](#) (DMA_Type *base, uint8_t channel)
Gets the DMA controller channel status.

DMA HAL driver

15.2.2 Data Structure Documentation

15.2.2.1 struct dma_channel_link_config_t

Data Fields

- [dma_channel_link_type_t linkType](#)
Channel link type.
- [uint32_t channel1](#)
Channel 1 configuration.
- [uint32_t channel2](#)
Channel 2 configuration.

15.2.2.2 struct dma_error_status_t

Data Fields

- [uint32_t dmaBytesToBeTransffered](#)
Bytes to be transferred.
- [bool dmaTransDone](#)
DMA channel transfer is done.
- [bool dmaBusy](#)
DMA is running.
- [bool dmaPendingRequest](#)
A transfer remains.
- [bool dmaDestBusError](#)
Bus error on destination address.
- [bool dmaSourceBusError](#)
Bus error on source address.
- [bool dmaConfigError](#)
Configuration error.

15.2.2.2.0.80 Field Documentation

15.2.2.2.0.80.1 [bool dma_error_status_t::dmaTransDone](#)

15.2.2.2.0.80.2 [bool dma_error_status_t::dmaBusy](#)

15.2.2.2.0.80.3 [bool dma_error_status_t::dmaPendingRequest](#)

15.2.3 Enumeration Type Documentation

15.2.3.1 enum dma_status_t

Enumerator

kStatus_DMA_InvalidArgument Parameter is not available for the current configuration.

kStatus_DMA_Fail Function operation failed.

15.2.3.2 enum dma_transfer_size_t

Enumerator

- kDmaTransfersize32bits* 32 bits are transferred for every read/write
- kDmaTransfersize8bits* 8 bits are transferred for every read/write
- kDmaTransfersize16bits* 16 bits are transferred for every read/write

15.2.3.3 enum dma_channel_link_type_t

Enumerator

- kDmaChannelLinkDisable* No channel link.
- kDmaChannelLinkChan1AndChan2* Perform a link to channel 1 after each cycle-steal transfer followed by a link and to channel 2 after the BCR decrements to zeros.
- kDmaChannelLinkChan1* Perform a link to channel 1 after each cycle-steal transfer.
- kDmaChannelLinkChan1AfterBCR0* Perform a link to channel 1 after the BCR decrements to zero.

15.2.3.4 enum dma_transfer_type_t

Enumerator

- kDmaPeripheralToMemory* Transfer from the peripheral to memory.
- kDmaMemoryToPeripheral* Transfer from the memory to peripheral.
- kDmaMemoryToMemory* Transfer from the memory to memory.
- kDmaPeripheralToPeripheral* Transfer from the peripheral to peripheral.

15.2.4 Function Documentation

15.2.4.1 void DMA_HAL_Init (DMA_Type * *base*, uint32_t *channel*)

Parameters

| | |
|----------------|--------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |

15.2.4.2 void DMA_HAL_ConfigTransfer (DMA_Type * *base*, uint32_t *channel*, dma_transfer_size_t *size*, dma_transfer_type_t *type*, uint32_t *sourceAddr*, uint32_t *destAddr*, uint32_t *length*)

DMA HAL driver

Parameters

| | |
|-------------------|--|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>size</i> | Size to be transferred on each DMA write/read. Source/Dest share the same write/read size. |
| <i>type</i> | Transfer type. |
| <i>sourceAddr</i> | Source address. |
| <i>destAddr</i> | Destination address. |
| <i>length</i> | Bytes to be transferred. |

15.2.4.3 `static void DMA_HAL_SetSourceAddr (DMA_Type * base, uint32_t channel, uint32_t address) [inline], [static]`

Each SAR contains the byte address used by the DMA to read data. The SAR_n is typically aligned on a 0-modulo-size boundary—that is on the natural alignment of the source data. Bits 31-20 of this register must be written with one of the only four allowed values. Each of these allowed values corresponds to a valid region of the devices' memory map. The allowed values are: 0x000x_xxxx 0x1FFx_xxxx 0x200x_xxxx 0x400x_xxxx After they are written with one of the allowed values, bits 31-20 read back as the written value. After they are written with any other value, bits 31-20 read back as an indeterminate value.

This function enables the request for a specified channel.

Parameters

| | |
|----------------|--|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>address</i> | memory address pointing to the source address. |

15.2.4.4 `static void DMA_HAL_SetDestAddr (DMA_Type * base, uint32_t channel, uint32_t address) [inline], [static]`

Each DAR contains the byte address used by the DMA to read data. The DAR_n is typically aligned on a 0-modulo-size boundary—that is on the natural alignment of the source data. Bits 31-20 of this register must be written with one of the only four allowed values. Each of these allowed values corresponds to a valid region of the devices' memory map. The allowed values are: 0x000x_xxxx 0x1FFx_xxxx 0x200x_xxxx 0x400x_xxxx After they are written with one of the allowed values, bits 31-20 read back as the written value. After they are written with any other value, bits 31-20 read back as an indeterminate value.

This function enables the request for specified channel.

Parameters

| | |
|----------------|----------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>address</i> | Destination address. |

15.2.4.5 static void DMA_HAL_SetTransferCount (DMA_Type * *base*, uint32_t *channel*, uint32_t *count*) [inline], [static]

Transfer bytes must be written with a value equal to or less than 0F_FFFFh. After being written with a value in this range, bits 23-20 of the BCR read back as 1110b. A write to the BCR with a value greater than 0F_FFFFh causes a configuration error when the channel starts to execute. After they are written with a value in this range, bits 23-20 of BCR read back as 1111b.

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>count</i> | bytes to be transferred. |

15.2.4.6 static uint32_t DMA_HAL_GetUnfinishedByte (DMA_Type * *base*, uint32_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |

Returns

unfinished bytes.

15.2.4.7 static void DMA_HAL_SetIntCmd (DMA_Type * *base*, uint8_t *channel*, bool *enable*) [inline], [static]

This function enables the request for specified channel.

DMA HAL driver

Parameters

| | |
|----------------|---|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | True means enable interrupt, false means disable. |

15.2.4.8 static void DMA_HAL_SetCycleStealCmd (DMA_Type * *base*, uint8_t *channel*, bool *enable*) [inline], [static]

If continuous mode is enabled, DMA continuously makes write/read transfers until BCR decrement to 0. If continuous mode is disabled, DMA write/read is only triggered on every request. s

Parameters

| | |
|----------------|--|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | 1 means cycle-steal mode, 0 means continuous mode. |

15.2.4.9 static void DMA_HAL_SetAutoAlignCmd (DMA_Type * *base*, uint8_t *channel*, bool *enable*) [inline], [static]

If auto-align is enabled, the appropriate address register increments, regardless of whether it is a source increment or a destination increment.

Parameters

| | |
|----------------|--|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | 0 means disable auto-align. 1 means enable auto-align. |

15.2.4.10 static void DMA_HAL_SetAsyncDmaRequestCmd (DMA_Type * *base*, uint8_t *channel*, bool *enable*) [inline], [static]

Enables/disables the a-synchronization mode in a STOP mode for each DMA channel.

Parameters

| | |
|----------------|---|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | 0 means disable DMA request a-sync. 1 means enable DMA request -. |

15.2.4.11 static void DMA_HAL_SetSourceIncrementCmd (DMA_Type * *base*, uint32_t *channel*, bool *enable*) [inline], [static]

Controls whether the source address increments after each successful transfer. If enabled, the SAR increments by 1,2,4 as determined by the transfer size.

Parameters

| | |
|----------------|----------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | Enabled/Disable increment. |

15.2.4.12 static void DMA_HAL_SetDestIncrementCmd (DMA_Type * *base*, uint32_t *channel*, bool *enable*) [inline], [static]

Controls whether the destination address increments after each successful transfer. If enabled, the DAR increments by 1,2,4 as determined by the transfer size.

Parameters

| | |
|----------------|----------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | Enabled/Disable increment. |

15.2.4.13 static void DMA_HAL_SetSourceTransferSize (DMA_Type * *base*, uint32_t *channel*, dma_transfer_size_t *transfersize*) [inline], [static]

Parameters

| | |
|-------------|-----------|
| <i>base</i> | DMA base. |
|-------------|-----------|

DMA HAL driver

| | |
|---------------------|------------------------------|
| <i>channel</i> | DMA channel. |
| <i>transfersize</i> | enum type for transfer size. |

15.2.4.14 `static void DMA_HAL_SetDestTransferSize (DMA_Type * base, uint32_t channel, dma_transfer_size_t transfersize) [inline], [static]`

Parameters

| | |
|---------------------|------------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>transfersize</i> | enum type for transfer size. |

15.2.4.15 `static void DMA_HAL_SetTriggerStartCmd (DMA_Type * base, uint32_t channel, bool enable) [inline], [static]`

When the DMA begins the transfer, the START bit is cleared automatically after one module clock and always reads as logic 0.

Parameters

| | |
|----------------|-------------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | Enable/disable trigger start. |

15.2.4.16 `static void DMA_HAL_SetSourceModulo (DMA_Type * base, uint32_t channel, dma_modulo_t modulo) [inline], [static]`

Parameters

| | |
|----------------|-----------------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>modulo</i> | enum data type for source modulo. |

15.2.4.17 `static void DMA_HAL_SetDestModulo (DMA_Type * base, uint32_t channel, dma_modulo_t modulo) [inline], [static]`

Parameters

| | |
|----------------|---------------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>modulo</i> | enum data type for dest modulo. |

15.2.4.18 `static void DMA_HAL_SetDmaRequestCmd (DMA_Type * base, uint32_t channel, bool enable) [inline], [static]`

Parameters

| | |
|----------------|-----------------------------|
| <i>base</i> | DMA base. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | Enable/disable dma request. |

15.2.4.19 `static void DMA_HAL_SetDisableRequestAfterDoneCmd (DMA_Type * base, uint32_t channel, bool enable) [inline], [static]`

Disables/enables the DMA request after a DMA DONE is generated. If it works in the loop mode, this bit should not be set.

Parameters

| | |
|----------------|---|
| <i>base</i> | DMA base address. |
| <i>channel</i> | DMA channel. |
| <i>enable</i> | 0 means DMA request would not be disabled after work done. 1 means disable. |

15.2.4.20 `void DMA_HAL_SetChanLink (DMA_Type * base, uint8_t channel, dma_channel_link_config_t * mode)`

DMA HAL driver

Parameters

| | |
|----------------|------------------------------|
| <i>base</i> | DMA base address. |
| <i>channel</i> | DMA channel. |
| <i>mode</i> | Mode of channel link in DMA. |

15.2.4.21 static void DMA_HAL_ClearStatus (DMA_Type * *base*, uint8_t *channel*) [inline], [static]

This function clears the status for a specified DMA channel. The error status and done status are cleared.

Parameters

| | |
|----------------|-------------------|
| <i>base</i> | DMA base address. |
| <i>channel</i> | DMA channel. |

15.2.4.22 dma_error_status_t DMA_HAL_GetStatus (DMA_Type * *base*, uint8_t *channel*)

Gets the status of the DMA channel. The user can get the error status, as to whether the descriptor is finished or there are bytes left.

Parameters

| | |
|----------------|-------------------|
| <i>base</i> | DMA base address. |
| <i>channel</i> | DMA channel. |

Returns

Status of the DMA channel.

15.3 DMA driver

15.3.1 Overview

This chapter describes the programming interface of the DMA Peripheral driver. The DMA driver requests, configures, and uses the DMA hardware. It supports module initialization and DMA channel configuration.

Data Structures

- struct `dma_channel_t`
Data structure for the DMA channel management. [More...](#)
- struct `dma_state_t`
Data structure for the DMA controller management. [More...](#)

Typedefs

- typedef void(* `dma_callback_t`)(void *parameter, `dma_channel_status_t` status)
A definition for the DMA channel callback function.

Enumerations

- enum `dma_channel_status_t` {
 `kDmaIdle`,
 `kDmaNormal`,
 `kDmaError` }
Channel status for the DMA channel.
- enum `dma_channel_type_t` {
 `kDmaInvalidChannel` = 0xFFU,
 `kDmaAnyChannel` = 0xFEU }
Type for the DMA channel, which is used for the DMA channel allocation.

Variables

- DMA_Type *const `g_dmaBase` [DMA_INSTANCE_COUNT]
Array for eDMA module register base address.
- DMAMUX_Type *const `g_dmamuxBase` [DMAMUX_INSTANCE_COUNT]
Array for DMAMUX module register base address.
- const IRQn_Type `g_dmaIrqId` [DMA_INSTANCE_COUNT][FSL_FEATURE_DMA_DMAMUX_CHANNELS]
Two-dimensional array for eDMA channel interrupt vector number.

DMA driver

DMA Driver

- [dma_status_t DMA_DRV_Init](#) ([dma_state_t](#) *state)
Initializes the DMA.
- [dma_status_t DMA_DRV_Deinit](#) (void)
De-initializes the DMA.
- [dma_status_t DMA_DRV_SetDestTransferSize](#) ([dma_channel_t](#) *chn, [uint32_t](#) transferSize)
Updates the DMA destination transfer size.
- [dma_status_t DMA_DRV_SetSourceTransferSize](#) ([dma_channel_t](#) *chn, [uint32_t](#) transferSize)
Updates the DMA source transfer size.
- [dma_status_t DMA_DRV_RegisterCallback](#) ([dma_channel_t](#) *chn, [dma_callback_t](#) callback, void *para)
Registers the callback function and a parameter.
- [uint32_t DMA_DRV_GetUnfinishedBytes](#) ([dma_channel_t](#) *chn)
Gets the number of unfinished bytes.
- [dma_status_t DMA_DRV_ClaimChannel](#) ([uint32_t](#) channel, [dma_request_source_t](#) source, [dma_channel_t](#) *chn)
Claims a DMA channel.
- [uint32_t DMA_DRV_RequestChannel](#) ([uint32_t](#) channel, [dma_request_source_t](#) source, [dma_channel_t](#) *chn)
Requests a DMA channel.
- [dma_status_t DMA_DRV_FreeChannel](#) ([dma_channel_t](#) *chn)
Frees DMA channel hardware and software resource.
- [dma_status_t DMA_DRV_StartChannel](#) ([dma_channel_t](#) *chn)
Starts a DMA channel.
- [dma_status_t DMA_DRV_StopChannel](#) ([dma_channel_t](#) *chn)
Stops a DMA channel.
- [dma_status_t DMA_DRV_ConfigTransfer](#) ([dma_channel_t](#) *chn, [dma_transfer_type_t](#) type, [uint32_t](#) size, [uint32_t](#) sourceAddr, [uint32_t](#) destAddr, [uint32_t](#) length)
Configures a transfer for the DMA.
- [dma_status_t DMA_DRV_ConfigChanLink](#) ([dma_channel_t](#) *chn, [dma_channel_link_config_t](#) *link_config)
Configures the channel link feature.
- void [DMA_DRV_IRQhandler](#) ([uint32_t](#) channel)
DMA IRQ handler for both an interrupt and an error.

15.3.2 Data Structure Documentation

15.3.2.1 struct dma_channel_t

Data Fields

- [uint8_t channel](#)
Channel number.
- [uint8_t dmamuxModule](#)
DMAMUX module index.
- [uint8_t dmamuxChannel](#)
DMAMUX module channel.

- [dma_callback_t](#) callback
Callback function for this channel.
- void * [parameter](#)
Parameter for the callback function.
- volatile [dma_channel_status_t](#) status
Channel status.

15.3.2.2 struct dma_state_t

15.3.3 Typedef Documentation

15.3.3.1 typedef void(* dma_callback_t)(void *parameter, dma_channel_status_t status)

A prototype for the callback function registered into the DMA driver.

15.3.4 Enumeration Type Documentation

15.3.4.1 enum dma_channel_status_t

A structure describing the status of the DMA channel. The user can get the status from the channel callback function.

Enumerator

- kDmaIdle* DMA channel is idle.
- kDmaNormal* DMA channel is occupied.
- kDmaError* Error occurs in the DMA channel.

15.3.4.2 enum dma_channel_type_t

Enumerator

- kDmaInvalidChannel* Macros indicating the failure of the channel request.
- kDmaAnyChannel* Macros used when requesting a channel. kEdmaAnyChannel means a request of dynamic channel allocation.

15.3.5 Function Documentation

15.3.5.1 dma_status_t DMA_DRV_Init (dma_state_t * state)

DMA driver

Parameters

| | |
|--------------|--|
| <i>state</i> | DMA state structure used for the DMA internal logic. |
|--------------|--|

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.2 `dma_status_t DMA_DRV_Deinit (void)`

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.3 `dma_status_t DMA_DRV_SetDestTransferSize (dma_channel_t * chn, uint32_t transferSize)`

Parameters

| | |
|---------------------|--------------------------------------|
| <i>chn</i> | A handler for the DMA channel |
| <i>transferSize</i> | Size of destination at each transfer |

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.4 `dma_status_t DMA_DRV_SetSourceTransferSize (dma_channel_t * chn, uint32_t transferSize)`

Parameters

| | |
|---------------------|---------------------------------|
| <i>chn</i> | A handler for the DMA channel |
| <i>transferSize</i> | Size of source at each transfer |

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.5 dma_status_t DMA_DRV_RegisterCallback (dma_channel_t * *chn*, dma_callback_t *callback*, void * *para*)

The user registers the callback function and a parameter for a specified DMA channel. When the channel interrupt or a channel error happens, the callback and the parameter are called. The user parameter is also provided to give a channel status.

Parameters

| | |
|-----------------|------------------------------------|
| <i>chn</i> | A handler for the DMA channel |
| <i>callback</i> | Callback function |
| <i>para</i> | A parameter for callback functions |

Returns

If successful, returns the kStatus_DMA_Success. Otherwise, it returns an error.

15.3.5.6 uint32_t DMA_DRV_GetUnfinishedBytes (dma_channel_t * *chn*)

Gets the bytes that remain to be transferred.

Parameters

| | |
|------------|-------------------------------|
| <i>chn</i> | A handler for the DMA channel |
|------------|-------------------------------|

Returns

If successful, returns the kStatus_DMA_Success. Otherwise, it returns an error.

15.3.5.7 dma_status_t DMA_DRV_ClaimChannel (uint32_t *channel*, dma_request_source_t *source*, dma_channel_t * *chn*)

Parameters

| | |
|----------------|-------------------------------------|
| <i>channel</i> | Channel index which needs to claim. |
| <i>source</i> | DMA request source. |

DMA driver

| | |
|------------|-------------------------------|
| <i>chn</i> | A handler for the DMA channel |
|------------|-------------------------------|

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.8 `uint32_t DMA_DRV_RequestChannel (uint32_t channel, dma_request_source_t source, dma_channel_t * chn)`

This function provides two ways to allocate a DMA channel: static and dynamic allocation. To allocate a channel dynamically, set the channel parameter with the value of `kDmaAnyChannel`. The driver searches all available free channels and assigns the first channel to the user. To allocate the channel statically, set the channel parameter with the value of a specified channel. If the channel is available, the driver assigns the channel. Notes: The user must provide a handler memory for the DMA channel. The driver initializes the handler and configures the handler memory.

Parameters

| | |
|----------------|---|
| <i>channel</i> | A DMA channel number. If a channel is assigned with a valid channel number, the DMA driver tries to assign a specified channel. If a channel is assigned with <code>kDmaAnyChannel</code> , the DMA driver searches all available channels and assigns the first channel to the user. |
| <i>source</i> | A DMA hardware request. |
| <i>chn</i> | Memory pointing to DMA channel. The user must ensure that the handler memory is valid and that it will not be released or changed by any other code before the channel <code>dma_free_channel()</code> operation. |

Returns

If the channel allocation is successful, the return value indicates the requested channel. If not, the driver returns a `kDmaInvalidChannel` value to indicate that the request operation has failed.

15.3.5.9 `dma_status_t DMA_DRV_FreeChannel (dma_channel_t * chn)`

This function frees the relevant software and hardware resources. Both the request and the free operations need to be called as a pair.

Parameters

| | |
|------------|---------------------------------|
| <i>chn</i> | Memory pointing to DMA channel. |
|------------|---------------------------------|

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.10 dma_status_t DMA_DRV_StartChannel (dma_channel_t * *chn*)

Starts a DMA channel. The driver starts a DMA channel by enabling the DMA request. A software start bit is not used in the DMA Peripheral driver.

Parameters

| | |
|------------|-------------------------------------|
| <i>chn</i> | Memory pointing to the DMA channel. |
|------------|-------------------------------------|

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.11 dma_status_t DMA_DRV_StopChannel (dma_channel_t * *chn*)

Parameters

| | |
|------------|-------------------------------------|
| <i>chn</i> | Memory pointing to the DMA channel. |
|------------|-------------------------------------|

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

**15.3.5.12 dma_status_t DMA_DRV_ConfigTransfer (dma_channel_t * *chn*,
dma_transfer_type_t *type*, uint32_t *size*, uint32_t *sourceAddr*, uint32_t
destAddr, uint32_t *length*)**

Configures a transfer for the DMA.

DMA driver

Parameters

| | |
|-------------------|--|
| <i>chn</i> | Memory pointing to the DMA channel. |
| <i>type</i> | Transfer type. |
| <i>size</i> | Size to be transferred on each DMA write/read. Source/Dest share the same write/read size. |
| <i>sourceAddr</i> | Source address. |
| <i>destAddr</i> | Destination address. |
| <i>length</i> | Bytes to be transferred. |

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.13 `dma_status_t DMA_DRV_ConfigChanLink (dma_channel_t * chn, dma_channel_link_config_t * link_config)`

Parameters

| | |
|--------------------|-------------------------------------|
| <i>chn</i> | Memory pointing to the DMA channel. |
| <i>link_config</i> | Configure of channel link in DMA. |

Returns

If successful, returns the `kStatus_DMA_Success`. Otherwise, it returns an error.

15.3.5.14 `void DMA_DRV_IRQhandler (uint32_t channel)`

Parameters

| | |
|----------------|---------------------|
| <i>channel</i> | DMA channel number. |
|----------------|---------------------|

15.3.6 Variable Documentation

15.3.6.1 `DMA_Type* const g_dmaBase[DMA_INSTANCE_COUNT]`

15.3.6.2 `DMAMUX_Type* const g_dmamuxBase[DMAMUX_INSTANCE_COUNT]`

15.3.6.3 `const IRQn_Type g_dmalrqld[DMA_INSTANCE_COUNT][FSL_FEATURE_DMA_DMAMUX_CHANNELS]`

15.4 DMA request

This section provides the DMA request resource.

15.4.1 DMA Initialization

To initialize the DMA module, call the `dma_init()` function. Configuration data structure does not need to be passed. This function enables the DMA module and clock automatically.

15.4.2 DMA Channel concept

DMA module consists of many channels. The DMA Peripheral driver is designed based on the channel concept. All tasks should start by requesting a DMA channel and end by freeing a DMA channel. By getting a channel allocated, the user can configure and run operations on the DMA module. If a channel is not allocated, a system error may occur.

15.4.3 DMA request concept

DMA request triggers a DMA transfer. The DMA request table is available in the device configuration chapters in a Reference Manual.

15.4.4 DMA Memory allocation

DMA peripheral driver does not allocate memory dynamically. The user must provide the allocated memory pointer for the driver and ensure that the memory is valid. Otherwise, a system error occurs. The user needs to provide the memory for the `[dma_channel_t]`. The driver must store the status data for every channel and the `dma_channel_t` is designed for this purpose.

15.4.5 DMA Call diagram

To use the DMA driver, follow these steps:

1. Initialize the DMA module: `dma_init()`.
2. Request a DMA channel: `dma_request_channel()`.
3. Configure the TCD: `dma_config_transfer()`.
4. Register callback function: `dma_register_callback()`.
5. Start the DMA channel: `dma_start_channel()`.
6. [OPTION] Stop the DMA channel: `dma_stop_channel()`.
7. Free the DMA channel: `dma_free_channel()`.

This example shows how to initialize and configure a memory-to-memory transfer:

DMA request

```

uint32_t j, temp;
dma_channel_t chan_handler;
uint8_t *srcAddr, *destAddr;
fsl_rtos_status syncStatus;

srcAddr = malloc(kDmaTestBufferSize);
destAddr = malloc(kDmaTestBufferSize);
if (((uint32_t)srcAddr == 0x0U) & ((uint32_t)destAddr == 0x0U))
{
    printf("Fali to allocate memory for test! \r\n");
    goto error;
}

// Init the memory buffer. //
for (j = 0; j < kDmaTestBufferSize; j++)
{
    srcAddr[j] = j;
    destAddr[j] = 0;
}

temp = dma_request_channel(channel, kDmaRequestMux0AlwaysOn62, &chan_handler);
if (temp != channel)
{
    printf("Failed to request channel %d !\r\n", channel);
    goto error;
}

dma_config_transfer(&chan_handler, kDmaMemoryToMemory,
                   0x1U,
                   (uint32_t)srcAddr, (uint32_t)destAddr,
                   kDmaTestBufferSize);

dma_register_callback(&chan_handler, test_callback, &chan_handler);

dma_start_channel(&chan_handler);
//Wait until channel complete...
dma_stop_channel(&chan_handler);
dma_free_channel(&chan_handler);

```

15.5 DMAMUX HAL driver

15.5.1 Overview

This section describes the programming interface of the DMAMUX HAL module.

Enumerations

- enum `dmamux_dma_request_source` { `kDmamuxDmaRequestSource = 64U` }
A constant for the length of the DMA hardware source.

DMAMUX HAL function

- void `DMAMUX_HAL_Init` (DMAMUX_Type *base)
Initializes the DMAMUX module to the reset state.
- static void `DMAMUX_HAL_SetChannelCmd` (DMAMUX_Type *base, uint32_t channel, bool enable)
Enables/Disables the DMAMUX channel.
- static void `DMAMUX_HAL_SetTriggerSource` (DMAMUX_Type *base, uint32_t channel, uint8_t source)
Configures the DMA request for the DMAMUX channel.

15.5.2 Enumeration Type Documentation

15.5.2.1 enum dmamux_dma_request_source

This structure is used inside the DMA driver.

Enumerator

kDmamuxDmaRequestSource Maximum number of the DMA requests allowed for the DMA mux.

15.5.3 Function Documentation

15.5.3.1 void DMAMUX_HAL_Init (DMAMUX_Type * base)

Initializes the DMAMUX module to the reset state.

Parameters

DMAMUX HAL driver

| | |
|-------------|--|
| <i>base</i> | Register base address for DMAMUX module. |
|-------------|--|

15.5.3.2 static void DMAMUX_HAL_SetChannelCmd (DMAMUX_Type * *base*, uint32_t *channel*, bool *enable*) [inline], [static]

Enables the hardware request. If enabled, the hardware request is sent to the corresponding DMA channel.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for DMAMUX module. |
| <i>channel</i> | DMAMUX channel number. |
| <i>enable</i> | Enables (true) or Disables (false) DMAMUX channel. |

15.5.3.3 static void DMAMUX_HAL_SetTriggerSource (DMAMUX_Type * *base*, uint32_t *channel*, uint8_t *source*) [inline], [static]

Sets the trigger source for the DMA channel. The trigger source is in the file fsl_dma_request.h.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for DMAMUX module. |
| <i>channel</i> | DMAMUX channel number. |
| <i>source</i> | DMA request source. |

Chapter 16

Serial Peripheral Interface (DSPI)

16.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Serial Peripheral Interface (DSPI) block of Kinetis K- and V-series devices. For L-series Kinetis devices, see the SPI module driver.

Modules

- [DSPI HAL driver](#)
- [DSPI Master Driver](#)
- [DSPI Shared IRQ Driver](#)
- [DSPI Slave Driver](#)

DSPI HAL driver

16.2 DSPI HAL driver

16.2.1 Overview

This section describes the programming interface of the DSPI HAL driver.

Files

- file [fsl_dspi_hal.h](#)

Data Structures

- struct [dspi_data_format_config_t](#)
DSPI data format settings configuration structure. [More...](#)
- struct [dspi_baud_rate_divisors_t](#)
DSPI baud rate divisors settings configuration structure. [More...](#)
- struct [dspi_command_config_t](#)
DSPI command and data configuration structure. [More...](#)

Enumerations

- enum [dspi_status_t](#) { ,
kStatus_DSPI_SlaveTxUnderrun,
kStatus_DSPI_SlaveRxOverrun,
kStatus_DSPI_Timeout,
kStatus_DSPI_Busy,
kStatus_DSPI_NoTransferInProgress,
kStatus_DSPI_InvalidBitCount,
kStatus_DSPI_InvalidInstanceNumber,
kStatus_DSPI_OutOfRange,
kStatus_DSPI_InvalidParameter,
kStatus_DSPI_NonInit,
kStatus_DSPI_Initialized,
kStatus_DSPI_DMACHannelInvalid,
kStatus_DSPI_Error,
kStatus_DSPI_EdmaStcdUnaligned32Error }
Error codes for the DSPI driver.
- enum [dspi_master_slave_mode_t](#) {
kDspiMaster = 1,
kDspiSlave = 0 }
DSPI master or slave configuration.
- enum [dspi_clock_polarity_t](#) {
kDspiClockPolarity_ActiveHigh = 0,
kDspiClockPolarity_ActiveLow = 1 }

- DSPI clock polarity configuration for a given CTAR.*

 - enum `dspi_clock_phase_t` {
`kDspiClockPhase_FirstEdge` = 0,
`kDspiClockPhase_SecondEdge` = 1 }
- DSPI clock phase configuration for a given CTAR.*

 - enum `dspi_shift_direction_t` {
`kDspiMsbFirst` = 0,
`kDspiLsbFirst` = 1 }
- DSPI data shifter direction options for a given CTAR.*

 - enum `dspi_ctar_selection_t` {
`kDspiCtar0` = 0,
`kDspiCtar1` = 1 }
- DSPI Clock and Transfer Attributes Register (CTAR) selection.*

 - enum `dspi_pcs_polarity_config_t` {
`kDspiPcs_ActiveHigh` = 0,
`kDspiPcs_ActiveLow` = 1 }
- DSPI Peripheral Chip Select (PCS) Polarity configuration.*

 - enum `dspi_which_pcs_config_t` {
`kDspiPcs0` = 1 << 0,
`kDspiPcs1` = 1 << 1,
`kDspiPcs2` = 1 << 2,
`kDspiPcs3` = 1 << 3,
`kDspiPcs4` = 1 << 4,
`kDspiPcs5` = 1 << 5 }
- DSPI Peripheral Chip Select (PCS) configuration (which PCS to configure)*

 - enum `dspi_master_sample_point_t` {
`kDspiSckToSin_0Clock` = 0,
`kDspiSckToSin_1Clock` = 1,
`kDspiSckToSin_2Clock` = 2 }
- DSPI Sample Point: Controls when the DSPI master samples SIN in Modified Transfer Format.*

 - enum `dspi_dma_or_int_mode_t` {
`kDspiGenerateIntReq` = 0,
`kDspiGenerateDmaReq` = 1 }
- DSPI Tx FIFO Fill and Rx FIFO Drain DMA or Interrupt configuration.*

 - enum `dspi_status_and_interrupt_request_t` {
`kDspiTxComplete` = SPI_RSER_TCF_RE_SHIFT,
`kDspiTxAndRxStatus` = SPI_SR_TXRXS_SHIFT,
`kDspiEndOfQueue` = SPI_RSER_EOQF_RE_SHIFT,
`kDspiTxFifoUnderflow` = SPI_RSER_TFUF_RE_SHIFT,
`kDspiTxFifoFillRequest` = SPI_RSER_TFFF_RE_SHIFT,
`kDspiRxFifoOverflow` = SPI_RSER_RFOF_RE_SHIFT,
`kDspiRxFifoDrainRequest` = SPI_RSER_RFDF_RE_SHIFT }
- DSPI status flags and interrupt request enable.*

 - enum `dspi_delay_type_t` {
`kDspiPcsToSck` = 1,
`kDspiLastSckToPcs` = 2,
`kDspiAfterTransfer` = 3 }

DSPI HAL driver

DSPI delay type selection.

Configuration

- void **DSPI_HAL_Init** (SPI_Type *base)
Restores the DSPI to reset the configuration.
- static void **DSPI_HAL_Enable** (SPI_Type *base)
Enables the DSPI peripheral and sets the MCR MDIS to 0.
- static void **DSPI_HAL_Disable** (SPI_Type *base)
Disables the DSPI peripheral, sets MCR MDIS to 1.
- uint32_t **DSPI_HAL_SetBaudRate** (SPI_Type *base, **dspi_ctar_selection_t** whichCtar, uint32_t bitsPerSec, uint32_t sourceClockInHz)
Sets the DSPI baud rate in bits per second.
- void **DSPI_HAL_SetBaudDivisors** (SPI_Type *base, **dspi_ctar_selection_t** whichCtar, const **dspi_baud_rate_divisors_t** *divisors)
Configures the baud rate divisors manually.
- static void **DSPI_HAL_SetMasterSlaveMode** (SPI_Type *base, **dspi_master_slave_mode_t** mode)
Configures the DSPI for master or slave.
- static bool **DSPI_HAL_IsMaster** (SPI_Type *base)
Returns whether the DSPI module is in master mode.
- static void **DSPI_HAL_SetContinuousSckCmd** (SPI_Type *base, bool enable)
Configures the DSPI for the continuous SCK operation.
- static void **DSPI_HAL_SetRxFifoOverwriteCmd** (SPI_Type *base, bool enable)
Configures the DSPI received FIFO overflow overwrite enable.
- void **DSPI_HAL_SetPcsPolarityMode** (SPI_Type *base, **dspi_which_pcs_config_t** pcs, **dspi_pcs_polarity_config_t** activeLowOrHigh)
Configures the DSPI peripheral chip select polarity.
- void **DSPI_HAL_SetFifoCmd** (SPI_Type *base, bool enableTxFifo, bool enableRxFifo)
Enables (or disables) the DSPI FIFOs.
- void **DSPI_HAL_SetFlushFifoCmd** (SPI_Type *base, bool enableFlushTxFifo, bool enableFlushRxFifo)
Flushes the DSPI FIFOs.
- static void **DSPI_HAL_SetDatainSamplepointMode** (SPI_Type *base, **dspi_master_sample_point_t** samplePnt)
Configures the time when the DSPI master samples SIN in the Modified Transfer Format.
- static void **DSPI_HAL_StartTransfer** (SPI_Type *base)
Starts the DSPI transfers, clears HALT bit in MCR.
- static void **DSPI_HAL_StopTransfer** (SPI_Type *base)
Stops (halts) DSPI transfers, sets HALT bit in MCR.
- **dspi_status_t** **DSPI_HAL_SetDataFormat** (SPI_Type *base, **dspi_ctar_selection_t** whichCtar, const **dspi_data_format_config_t** *config)
Configures the data format for a particular CTAR.
- void **DSPI_HAL_SetDelay** (SPI_Type *base, **dspi_ctar_selection_t** whichCtar, uint32_t prescaler, uint32_t scaler, **dspi_delay_type_t** whichDelay)
Manually configures the delay prescaler and scaler for a particular CTAR.
- uint32_t **DSPI_HAL_CalculateDelay** (SPI_Type *base, **dspi_ctar_selection_t** whichCtar, **dspi_delay_type_t** whichDelay, uint32_t sourceClockInHz, uint32_t delayInNanoSec)
Calculates the delay prescaler and scaler based on the desired delay input in nanoseconds.
- static uint32_t **DSPI_HAL_GetMasterPushrRegAddr** (SPI_Type *base)

- Gets the DSPI master PUSHHR data register address for DMA operation.*
 - static uint32_t **DSPI_HAL_GetSlavePushrRegAddr** (SPI_Type *base)
- Gets the DSPI slave PUSHHR data register address for DMA operation.*
 - static uint32_t **DSPI_HAL_GetPoprRegAddr** (SPI_Type *base)
- Gets the DSPI POPR data register address for DMA operation.*

Interrupts

- void **DSPI_HAL_SetTxFifoFillDmaIntMode** (SPI_Type *base, **dspi_dma_or_int_mode_t** mode, bool enable)
 - Configures the DSPI Tx FIFO fill request to generate DMA or interrupt requests.*
- void **DSPI_HAL_SetRxFifoDrainDmaIntMode** (SPI_Type *base, **dspi_dma_or_int_mode_t** mode, bool enable)
 - Configures the DSPI Rx FIFO Drain request to generate DMA or interrupt requests.*
- void **DSPI_HAL_SetIntMode** (SPI_Type *base, **dspi_status_and_interrupt_request_t** interruptSrc, bool enable)
 - Configures the DSPI interrupts.*
- static bool **DSPI_HAL_GetIntMode** (SPI_Type *base, **dspi_status_and_interrupt_request_t** interruptSrc)
 - Gets DSPI interrupt configuration, returns if interrupt request is enabled or disabled.*

Status

- static bool **DSPI_HAL_GetStatusFlag** (SPI_Type *base, **dspi_status_and_interrupt_request_t** statusFlag)
 - Gets the DSPI status flag state.*
- static void **DSPI_HAL_ClearStatusFlag** (SPI_Type *base, **dspi_status_and_interrupt_request_t** statusFlag)
 - Clears the DSPI status flag.*

Data transfer

- static uint32_t **DSPI_HAL_ReadData** (SPI_Type *base)
 - Reads data from the data buffer.*
- static void **DSPI_HAL_WriteDataSlavemode** (SPI_Type *base, uint32_t data)
 - Writes data into the data buffer, slave mode.*
- void **DSPI_HAL_WriteDataSlavemodeBlocking** (SPI_Type *base, uint32_t data)
 - Writes data into the data buffer, slave mode and waits till data was transmitted and return.*
- void **DSPI_HAL_WriteDataMastermode** (SPI_Type *base, **dspi_command_config_t** *command, uint16_t data)
 - Writes data into the data buffer, master mode.*
- void **DSPI_HAL_WriteDataMastermodeBlocking** (SPI_Type *base, **dspi_command_config_t** *command, uint16_t data)
 - Writes data into the data buffer, master mode and waits till complete to return.*
- static void **DSPI_HAL_WriteCmdDataMastermode** (SPI_Type *base, uint32_t data)
 - Writes a 32-bit data word (16-bit command appended with 16-bit data) into the data buffer, master mode.*

DSPI HAL driver

- void [DSPI_HAL_WriteCmdDataMastermodeBlocking](#) (SPI_Type *base, uint32_t data)
Writes a 32-bit data word (16-bit command appended with 16-bit data) into the data buffer, master mode and waits till complete to return.
- static uint32_t [DSPI_HAL_GetTransferCount](#) (SPI_Type *base)
Gets the transfer count.
- static void [DSPI_HAL_PresetTransferCount](#) (SPI_Type *base, uint16_t presetValue)
Pre-sets the transfer count.
- uint32_t [DSPI_HAL_GetFormattedCommand](#) (SPI_Type *base, [dspi_command_config_t](#) *command)
Returns the DSPI command word formatted to the PUSHHR data register bit field.

16.2.2 Data Structure Documentation

16.2.2.1 struct dspi_data_format_config_t

This structure contains the data format settings. These settings apply to a specific CTARn register, which the user must provide in this structure.

Data Fields

- uint32_t [bitsPerFrame](#)
Bits per frame, minimum 4, maximum 16.
- [dspi_clock_polarity_t](#) [clkPolarity](#)
Active high or low clock polarity.
- [dspi_clock_phase_t](#) [clkPhase](#)
Clock phase setting to change and capture data.
- [dspi_shift_direction_t](#) [direction](#)
MSB or LSB data shift direction This setting relevant only in master mode and can be ignored in slave mode.

16.2.2.2 struct dspi_baud_rate_divisors_t

Note: These settings are relevant only in master mode. This structure contains the baud rate divisor settings, which provides the user with the option to explicitly set these baud rate divisors. In addition, the user must also set the CTARn register with the divisor settings.

Data Fields

- bool [doubleBaudRate](#)
Double Baud rate parameter setting.
- uint32_t [prescaleDivisor](#)
Baud Rate Pre-scalar parameter setting.
- uint32_t [baudRateDivisor](#)
Baud Rate scaler parameter setting.

16.2.2.3 struct `dspi_command_config_t`

Note: This structure is used with the PUSH register, which provides the means to write to the Tx FIFO. Data written to this register is transferred to the Tx FIFO. Eight or sixteen-bit write accesses to the PUSH register transfer all 32 register bits to the Tx FIFO. The register structure is different in master and slave modes. In master mode, the register provides 16-bit command and 16-bit data to the Tx FIFO. In slave mode only 16-bit data may be written (this may be contrary to some older documentation which erroneously states that a 32-bit value may be written).

Data Fields

- bool `isChipSelectContinuous`
Option to enable the continuous assertion of chip select between transfers.
- `dspi_ctar_selection_t` `whichCtar`
The desired Clock and Transfer Attributes Register (CTAR) to use for CTAS.
- `dspi_which_pcs_config_t` `whichPcs`
The desired PCS signal to use for the data transfer.
- bool `isEndOfQueue`
Signals that the current transfer is the last in the queue.
- bool `clearTransferCount`
Clears SPI_TCNT field; cleared before transmission starts.

16.2.3 Enumeration Type Documentation

16.2.3.1 enum `dspi_status_t`

Enumerator

- `kStatus_DSPI_SlaveTxUnderrun`** DSPI Slave Tx Under run error.
- `kStatus_DSPI_SlaveRxOverrun`** DSPI Slave Rx Overrun error.
- `kStatus_DSPI_Timeout`** DSPI transfer timed out.
- `kStatus_DSPI_Busy`** DSPI instance is already busy performing a transfer.
- `kStatus_DSPI_NoTransferInProgress`** Attempt to abort a transfer when no transfer was in progress.

- `kStatus_DSPI_InvalidBitCount`** bits-per-frame value not valid
- `kStatus_DSPI_InvalidInstanceNumber`** DSPI instance number does not match current count.
- `kStatus_DSPI_OutOfRange`** DSPI out-of-range error.
- `kStatus_DSPI_InvalidParameter`** DSPI invalid parameter error.
- `kStatus_DSPI_NonInit`** DSPI driver does not initialize, not ready.
- `kStatus_DSPI_Initialized`** DSPI driver has initialized, cannot re-initialize.
- `kStatus_DSPI_DMACHannelInvalid`** DSPI driver could not request DMA channel(s)
- `kStatus_DSPI_Error`** DSPI driver error.
- `kStatus_DSPI_EdmaStcdUnaligned32Error`** DSPI Edma driver STCD unaligned to 32byte error.

DSPI HAL driver

16.2.3.2 enum dspi_master_slave_mode_t

Enumerator

kDspiMaster DSPI peripheral operates in master mode.

kDspiSlave DSPI peripheral operates in slave mode.

16.2.3.3 enum dspi_clock_polarity_t

Enumerator

kDspiClockPolarity_ActiveHigh Active-high DSPI clock (idles low)

kDspiClockPolarity_ActiveLow Active-low DSPI clock (idles high)

16.2.3.4 enum dspi_clock_phase_t

Enumerator

kDspiClockPhase_FirstEdge Data is captured on the leading edge of the SCK and changed on the following edge.

kDspiClockPhase_SecondEdge Data is changed on the leading edge of the SCK and captured on the following edge.

16.2.3.5 enum dspi_shift_direction_t

Enumerator

kDspiMsbFirst Data transfers start with most significant bit.

kDspiLsbFirst Data transfers start with least significant bit.

16.2.3.6 enum dspi_ctar_selection_t

Enumerator

kDspiCtar0 CTAR0 selection option for master or slave mode.

kDspiCtar1 CTAR1 selection option for master mode only.

16.2.3.7 enum dspi_pcs_polarity_config_t

Enumerator

kDspiPcs_ActiveHigh PCS Active High (idles low)

kDspiPcs_ActiveLow PCS Active Low (idles high)

16.2.3.8 enum dsp_i_which_pcs_config_t

Enumerator

kDspiPcs0 PCS[0].
kDspiPcs1 PCS[1].
kDspiPcs2 PCS[2].
kDspiPcs3 PCS[3].
kDspiPcs4 PCS[4].
kDspiPcs5 PCS[5].

16.2.3.9 enum dsp_i_master_sample_point_t

This field is valid only when CPHA bit in CTAR register is 0.

Enumerator

kDspiSckToSin_0Clock 0 system clocks between SCK edge and SIN sample
kDspiSckToSin_1Clock 1 system clock between SCK edge and SIN sample
kDspiSckToSin_2Clock 2 system clocks between SCK edge and SIN sample

16.2.3.10 enum dsp_i_dma_or_int_mode_t

Enumerator

kDspiGenerateIntReq Desired flag generates an Interrupt request.
kDspiGenerateDmaReq Desired flag generates a DMA request.

16.2.3.11 enum dsp_i_status_and_interrupt_request_t

Enumerator

kDspiTxComplete TCF status/interrupt enable.
kDspiTxAndRxStatus TXRXS status only, no interrupt.
kDspiEndOfQueue EOQF status/interrupt enable.
kDspiTxFifoUnderflow TFUF status/interrupt enable.
kDspiTxFifoFillRequest TFFF status/interrupt enable.
kDspiRxFifoOverflow RFOF status/interrupt enable.
kDspiRxFifoDrainRequest RFDF status/interrupt enable.

DSPI HAL driver

16.2.3.12 enum dspi_delay_type_t

Enumerator

- kDspiPcsToSck* PCS-to-SCK delay.
- kDspiLastSckToPcs* Last SCK edge to PCS delay.
- kDspiAfterTransfer* Delay between transfers.

16.2.4 Function Documentation

16.2.4.1 void DSPI_HAL_Init (SPI_Type * *base*)

This function basically resets all of the DSPI registers to their default setting including disabling the module.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

16.2.4.2 static void DSPI_HAL_Enable (SPI_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

16.2.4.3 static void DSPI_HAL_Disable (SPI_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

16.2.4.4 uint32_t DSPI_HAL_SetBaudRate (SPI_Type * *base*, dspi_ctar_selection_t *whichCtar*, uint32_t *bitsPerSec*, uint32_t *sourceClockInHz*)

This function takes in the desired bitsPerSec (baud rate) and calculates the nearest possible baud rate without exceeding the desired baud rate, and returns the calculated baud rate in bits-per-second. It requires that the caller also provide the frequency of the module source clock (in Hertz).

Parameters

| | |
|-------------------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>whichCtar</i> | The desired Clock and Transfer Attributes Register (CTAR) of the type dspi_ctar_selection_t |
| <i>bitsPerSec</i> | The desired baud rate in bits per second |
| <i>sourceClockIn-Hz</i> | Module source input clock in Hertz |

Returns

The actual calculated baud rate

16.2.4.5 void DSPI_HAL_SetBaudDivisors (SPI_Type * *base*, dspi_ctar_selection_t *whichCtar*, const dspi_baud_rate_divisors_t * *divisors*)

This function allows the caller to manually set the baud rate divisors in the event that these dividers are known and the caller does not wish to call the DSPI_HAL_SetBaudRate function.

Parameters

| | |
|------------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>whichCtar</i> | The desired Clock and Transfer Attributes Register (CTAR) of type dspi_ctar_selection_t |
| <i>divisors</i> | Pointer to a structure containing the user defined baud rate divisor settings |

16.2.4.6 static void DSPI_HAL_SetMasterSlaveMode (SPI_Type * *base*, dspi_master_slave_mode_t *mode*) [inline], [static]

Parameters

| | |
|-------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>mode</i> | Mode setting (master or slave) of type dspi_master_slave_mode_t |

16.2.4.7 static bool DSPI_HAL_IsMaster (SPI_Type * *base*) [inline], [static]

DSPI HAL driver

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

Returns true if the module is in master mode or false if the module is in slave mode.

16.2.4.8 static void DSPI_HAL_SetContinuousSckCmd (SPI_Type * *base*, bool *enable*) [inline], [static]

Parameters

| | |
|---------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>enable</i> | Enables (true) or disables(false) continuous SCK operation. |

16.2.4.9 static void DSPI_HAL_SetRxFifoOverwriteCmd (SPI_Type * *base*, bool *enable*) [inline], [static]

When enabled, this function allows incoming receive data to overwrite the existing data in the receive shift register when the Rx FIFO is full. Otherwise when disabled, the incoming data is ignored when the RX FIFO is full.

Parameters

| | |
|---------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>enable</i> | If enabled (true), allows incoming data to overwrite Rx FIFO contents when full, else incoming data is ignored. |

16.2.4.10 void DSPI_HAL_SetPcsPolarityMode (SPI_Type * *base*, dsp_i_which_pcs_config_t *pcs*, dsp_i_pcs_polarity_config_t *activeLowOrHigh*)

This function takes in the desired peripheral chip select (PCS) and it's corresponding desired polarity and configures the PCS signal to operate with the desired characteristic.

Parameters

| | |
|------------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>pcs</i> | The particular peripheral chip select (parameter value is of type dspi_which_pcs_-config_t) for which we wish to apply the active high or active low characteristic. |
| <i>activeLowOrHigh</i> | The setting for either "active high, inactive low (0)" or "active low, inactive high(1)" of type dspi_pcs_polarity_config_t. |

16.2.4.11 void DSPI_HAL_SetFifoCmd (SPI_Type * *base*, bool *enableTxFifo*, bool *enableRxFifo*)

This function allows the caller to disable/enable the Tx and Rx FIFOs (independently). Note that to disable, the caller must pass in a logic 0 (false) for the particular FIFO configuration. To enable, the caller must pass in a logic 1 (true).

Parameters

| | |
|---------------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>enableTxFifo</i> | Disables (false) the TX FIFO, else enables (true) the TX FIFO |
| <i>enableRxFifo</i> | Disables (false) the RX FIFO, else enables (true) the RX FIFO |

16.2.4.12 void DSPI_HAL_SetFlushFifoCmd (SPI_Type * *base*, bool *enableFlushTxFifo*, bool *enableFlushRxFifo*)

Parameters

| | |
|--------------------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>enableFlushTxFifo</i> | Flushes (true) the Tx FIFO, else do not flush (false) the Tx FIFO |
| <i>enableFlushRxFifo</i> | Flushes (true) the Rx FIFO, else do not flush (false) the Rx FIFO |

16.2.4.13 static void DSPI_HAL_SetDataInSamplepointMode (SPI_Type * *base*, dspi_master_sample_point_t *samplePnt*) [inline], [static]

This function controls when the DSPI master samples SIN (data in) in the Modified Transfer Format. Note that this is valid only when the CPHA bit in the CTAR register is 0.

DSPI HAL driver

Parameters

| | |
|------------------|---|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>samplePnt</i> | selects when the data in (SIN) is sampled, of type dsp_i_master_sample_point_t. This value selects either 0, 1, or 2 system clocks between the SCK edge and the SIN (data in) sample. |

16.2.4.14 static void DSPI_HAL_StartTransfer (SPI_Type * *base*) [inline], [static]

This function call called whenever the module is ready to begin data transfers in either master or slave mode.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

16.2.4.15 static void DSPI_HAL_StopTransfer (SPI_Type * *base*) [inline], [static]

This function call stops data transfers in either master or slave mode.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

16.2.4.16 dsp_i_status_t DSPI_HAL_SetDataFormat (SPI_Type * *base*, dsp_i_ctar_selection_t *whichCtar*, const dsp_i_data_format_config_t * *config*)

This function configures the bits-per-frame, polarity, phase, and shift direction for a particular CTAR. An example use case is as follows:

```

dsp_i_data_format_config_t dataFormat;
dataFormat.bitsPerFrame = 16;
dataFormat.clkPolarity = kDspiClockPolarity_ActiveLow;
dataFormat.clkPhase = kDspiClockPhase_FirstEdge;
dataFormat.direction = kDspiMsbFirst;
DSPI_HAL_SetDataFormat(instance, kDspiCtar0, &dataFormat);

```

Parameters

| | |
|------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>whichCtar</i> | The desired Clock and Transfer Attributes Register (CTAR) of type dspicatar_selection_t. |
| <i>config</i> | Pointer to structure containing user defined data format configuration settings. |

Returns

An error code or kStatus_DSPI_Success

16.2.4.17 void DSPI_HAL_SetDelay (SPI_Type * *base*, dspicatar_selection_t *whichCtar*, uint32_t *prescaler*, uint32_t *scaler*, dspidelay_type_t *whichDelay*)

This function configures the PCS to SCK delay pre-scalar (PCSSCK) and scalar (CSSCK), after SCK delay pre-scalar (PASC) and scalar (ASC), and the delay after transfer pre-scalar (PDT) and scalar (DT).

These delay names are available in type dspidelay_type_t.

The user passes which delay they want to configure along with the prescaler and scaler value. This allows the user to directly set the prescaler/scaler values if they have pre-calculated them or if they simply wish to manually increment either value.

Parameters

| | |
|-------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>whichCtar</i> | The desired Clock and Transfer Attributes Register (CTAR) of type dspicatar_selection_t. |
| <i>prescaler</i> | The prescaler delay value (can be an integer 0, 1, 2, or 3). |
| <i>scaler</i> | The scaler delay value (can be any integer between 0 to 15). |
| <i>whichDelay</i> | The desired delay to configure, must be of type dspidelay_type_t |

16.2.4.18 uint32_t DSPI_HAL_CalculateDelay (SPI_Type * *base*, dspicatar_selection_t *whichCtar*, dspidelay_type_t *whichDelay*, uint32_t *sourceClockInHz*, uint32_t *delayInNanoSec*)

This function calculates the values for: PCS to SCK delay pre-scalar (PCSSCK) and scalar (CSSCK), or After SCK delay pre-scalar (PASC) and scalar (ASC), or Delay after transfer pre-scalar (PDT) and scalar (DT).

These delay names are available in type dspidelay_type_t.

The user passes which delay they want to configure along with the desired delay value in nanoseconds. The function calculates the values needed for the prescaler and scaler and returning the actual calculated

DSPI HAL driver

delay as an exact delay match may not be possible. In this case, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. It is to the higher level peripheral driver to alert the user of an out of range delay input.

Parameters

| | |
|-------------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>whichCtar</i> | The desired Clock and Transfer Attributes Register (CTAR) of type dspic_tar_selection_t. |
| <i>whichDelay</i> | The desired delay to configure, must be of type dspic_delay_type_t |
| <i>sourceClockIn-Hz</i> | Module source input clock in Hertz |
| <i>delayInNano-Sec</i> | The desired delay value in nanoseconds. |

Returns

The actual calculated delay value.

16.2.4.19 static uint32_t DSPI_HAL_GetMasterPushrRegAddr (SPI_Type * *base*) [inline], [static]

This function gets the DSPI master PUSHR data register address as this value is needed for DMA operation.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

The DSPI master PUSHR data register address.

16.2.4.20 static uint32_t DSPI_HAL_GetSlavePushrRegAddr (SPI_Type * *base*) [inline], [static]

This function gets the DSPI slave PUSHR data register address as this value is needed for DMA operation.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

The DSPI slave PUSHHR data register address.

16.2.4.21 static uint32_t DSPI_HAL_GetPoprRegAddr (SPI_Type * *base*) [inline], [static]

This function gets the DSPI POPR data register address as this value is needed for DMA operation.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

The DSPI POPR data register address.

16.2.4.22 void DSPI_HAL_SetTxFifoFillDmaIntMode (SPI_Type * *base*, dsp_i_dma_or_int_mode_t *mode*, bool *enable*)

This function configures the DSPI Tx FIFO Fill flag to generate either an interrupt or DMA request. The user passes in which request they'd like to generate of type dsp_i_dma_or_int_mode_t and whether or not they wish to enable this request. Note, when disabling the request, the request type is don't care.

```

DSPI_HAL_SetTxFifoFillDmaIntMode(base,
    kDspiGenerateDmaReq, true); <- to enable DMA
DSPI_HAL_SetTxFifoFillDmaIntMode(base,
    kDspiGenerateIntReq, true); <- to enable Interrupt
DSPI_HAL_SetTxFifoFillDmaIntMode(base,
    kDspiGenerateIntReq, false); <- to disable
    
```

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

DSPI HAL driver

| | |
|---------------|--|
| <i>mode</i> | Configures the DSPI Tx FIFO Fill to generate an interrupt or DMA request |
| <i>enable</i> | Enable (true) or disable (false) the DSPI Tx FIFO Fill flag to generate requests |

16.2.4.23 void DSPI_HAL_SetRxFifoDrainDmaIntMode (SPI_Type * *base*, dsp_i_dma_or_int_mode_t *mode*, bool *enable*)

This function configures the DSPI Rx FIFO Drain flag to generate either an interrupt or a DMA request. The user passes in which request they'd like to generate of type `ds_pi_dma_or_int_mode_t` and whether or not they wish to enable this request. Note, when disabling the request, the request type is don't care.

```
DSPI_HAL_SetRxFifoDrainDmaIntMode(base,
    kDspiGenerateDmaReq, true); <- to enable DMA
DSPI_HAL_SetRxFifoDrainDmaIntMode(base,
    kDspiGenerateIntReq, true); <- to enable Interrupt
DSPI_HAL_SetRxFifoDrainDmaIntMode(base,
    kDspiGenerateIntReq, false); <- to disable
```

Parameters

| | |
|---------------|--|
| <i>base</i> | Module base pointer of type <code>SPI_Type</code> . |
| <i>mode</i> | Configures the Rx FIFO Drain to generate an interrupt or DMA request |
| <i>enable</i> | Enable (true) or disable (false) the Rx FIFO Drain flag to generate requests |

16.2.4.24 void DSPI_HAL_SetIntMode (SPI_Type * *base*, dsp_i_status_and_interrupt_request_t *interruptSrc*, bool *enable*)

This function configures the various interrupt sources of the DSPI. The parameters are base, interrupt source, and enable/disable setting. The interrupt source is a typedef enumeration whose value is the bit position of the interrupt source setting within the RSER register. In the DSPI, all interrupt configuration settings are in one register. The typedef enum equates each interrupt source to the bit position defined in the device header file. The function uses these bit positions in its algorithm to enable/disable the interrupt source, where interrupt source is the `ds_pi_status_and_interrupt_request_t` type. Note, for Tx FIFO Fill and Rx FIFO Drain requests, use the functions: `DSPI_HAL_SetTxFifoFillDmaIntMode` and `DSPI_HAL_SetRxFifoDrainDmaIntMode` respectively as these requests can generate either an interrupt or DMA request.

```
DSPI_HAL_SetIntMode(base, kDspiTxComplete, true); <- example use-case
```

Parameters

| | |
|---------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>interruptSrc</i> | The interrupt source, of type dsp_i_status_and_interrupt_request_t |
| <i>enable</i> | Enable (true) or disable (false) the interrupt source to generate requests |

16.2.4.25 static bool DSPI_HAL_GetIntMode (SPI_Type * *base*, dsp_i_status_and_interrupt_request_t *interruptSrc*) [inline], [static]

This function returns the requested interrupt source setting (enabled or disabled, of type bool). The parameters to pass in are base and interrupt source. It utilizes the same enumeration definitions for the interrupt sources as described in the interrupt config function. The function uses these bit positions in its algorithm to obtain the desired interrupt source setting. Note, for Tx FIFO Fill and Rx FIFO Drain requests, this returns whether or not their requests are enabled.

```
getInterruptSetting = DSPI_HAL_GetIntMode(base,
    kDspiTxComplete);
```

Parameters

| | |
|---------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>interruptSrc</i> | The interrupt source, of type dsp_i_status_and_interrupt_request_t |

Returns

Configuration of interrupt request: enable (true) or disable (false).

16.2.4.26 static bool DSPI_HAL_GetStatusFlag (SPI_Type * *base*, dsp_i_status_and_interrupt_request_t *statusFlag*) [inline], [static]

The status flag is defined in the same enumeration as the interrupt source enable because the bit position of the interrupt source and corresponding status flag are the same in the RSER and SR registers. The function uses these bit positions in its algorithm to obtain the desired flag state, similar to the dsp_i_get_interrupt_config function.

```
getStatus = DSPI_HAL_GetStatusFlag(base, kDspiTxComplete);
```

DSPI HAL driver

Parameters

| | |
|-------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>statusFlag</i> | The status flag, of type dspi_status_and_interrupt_request_t |

Returns

State of the status flag: asserted (true) or not-asserted (false)

16.2.4.27 static void DSPI_HAL_ClearStatusFlag (SPI_Type * *base*, dspi_status_and_interrupt_request_t *statusFlag*) [inline], [static]

This function clears the desired status bit by using a write-1-to-clear. The user passes in the base and the desired status bit to clear. The list of status bits is defined in the dspi_status_and_interrupt_request_t. The function uses these bit positions in its algorithm to clear the desired flag state. Example usage:

```
DSPI_HAL_ClearStatusFlag(base, kDspiTxComplete);
```

Parameters

| | |
|-------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>statusFlag</i> | The status flag, of type dspi_status_and_interrupt_request_t |

16.2.4.28 static uint32_t DSPI_HAL_ReadData (SPI_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

The data from the read data buffer

16.2.4.29 static void DSPI_HAL_WriteDataSlavemode (SPI_Type * *base*, uint32_t *data*) [inline], [static]

In slave mode, up to 16-bit words may be written.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>data</i> | The data to send |

16.2.4.30 void DSPI_HAL_WriteDataSlavemodeBlocking (SPI_Type * *base*, uint32_t *data*)

In slave mode, up to 16-bit words may be written. The function first clears transmit complete flag then writes data into data register, and finally wait tills the data is transmitted.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>data</i> | The data to send |

16.2.4.31 void DSPI_HAL_WriteDataMastermode (SPI_Type * *base*, dspicommandconfig_t * *command*, uint16_t *data*)

In master mode, the 16-bit data is appended to the 16-bit command info. The command portion provides characteristics of the data such as: optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example:

```

dspicommandconfig_t commandConfig;
commandConfig.isChipSelectContinuous = true;
commandConfig.whichCtar = kDspiCtar0;
commandConfig.whichPcs = kDspiPcs1;
commandConfig.clearTransferCount = false;
commandConfig.isEndOfQueue = false;
DSPI_HAL_WriteDataMastermode(base, &commandConfig, dataWord);

```

Parameters

| | |
|----------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>command</i> | Pointer to command structure |

DSPI HAL driver

| | |
|-------------|--------------------------|
| <i>data</i> | The data word to be sent |
|-------------|--------------------------|

16.2.4.32 void DSPI_HAL_WriteDataMastermodeBlocking (SPI_Type * *base*, dspi_command_config_t * *command*, uint16_t *data*)

In master mode, the 16-bit data is appended to the 16-bit command info. The command portion provides characteristics of the data such as: optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example:

```
dspi_command_config_t commandConfig;
commandConfig.isChipSelectContinuous = true;
commandConfig.whichCtar = kDspiCtar0;
commandConfig.whichPcs = kDspiPcs1;
commandConfig.clearTransferCount = false;
commandConfig.isEndOfQueue = false;
DSPI_HAL_WriteDataMastermodeBlocking(base, &commandConfig, dataWord);
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running in order to transmit data (MCR[MDIS] & [HALT] = 0). Since the SPI is a synchronous protocol, receive data is available when transmit completes.

Parameters

| | |
|----------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>command</i> | Pointer to command structure |
| <i>data</i> | The data word to be sent |

16.2.4.33 static void DSPI_HAL_WriteCmdDataMastermode (SPI_Type * *base*, uint32_t *data*) [inline], [static]

In this function, the user must append the 16-bit data to the 16-bit command info then provide the total 32-bit word as the data to send. The command portion provides characteristics of the data such as: optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). The user is responsible for appending this command with the data to send. This is an example:

```
dataWord = <16-bit command> | <16-bit data>;
DSPI_HAL_WriteCmdDataMastermode(base, dataWord);
```

Parameters

| | |
|-------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>data</i> | The data word (command and data combined) to be sent |

16.2.4.34 void DSPI_HAL_WriteCmdDataMastermodeBlocking (SPI_Type * *base*, uint32_t *data*)

In this function, the user must append the 16-bit data to the 16-bit command info then provide the total 32-bit word as the data to send. The command portion provides characteristics of the data such as: optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). The user is responsible for appending this command with the data to send. This is an example:

```
dataWord = <16-bit command> | <16-bit data>;
DSPI_HAL_WriteCmdDataMastermodeBlocking(base, dataWord);
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running in order to transmit data (MCR[MDIS] & [HALT] = 0). Since the SPI is a synchronous protocol, receive data is available when transmit completes.

Parameters

| | |
|-------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>data</i> | The data word (command and data combined) to be sent |

16.2.4.35 static uint32_t DSPI_HAL_GetTransferCount (SPI_Type * *base*) [inline], [static]

This function returns the current value of the DSPI Transfer Count Register.

Parameters

| | |
|-------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
|-------------|---------------------------------------|

Returns

The current transfer count

DSPI HAL driver

16.2.4.36 `static void DSPI_HAL_PresetTransferCount (SPI_Type * base, uint16_t presetValue) [inline], [static]`

This function allows the caller to pre-set the DSI Transfer Count Register to a desired value up to 65535; Incrementing past this resets the counter back to 0.

Parameters

| | |
|--------------------|--|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>presetValue</i> | The desired pre-set value for the transfer counter |

**16.2.4.37 uint32_t DSPI_HAL_GetFormattedCommand (SPI_Type * *base*,
dspi_command_config_t * *command*)**

This function allows the caller to pass in the data command structure and returns the command word formatted according to the DSPI PUSHR register bit field placement. The user can then "OR" the returned command word with the desired data to send and use the function DSPI_HAL_WriteCmdDataMastermode or DSPI_HAL_WriteCmdDataMastermodeBlocking to write the entire 32-bit command data word to the PUSHR. This helps improve performance in cases where the command structure is constant. For example, the user calls this function before starting a transfer to generate the command word. When they are ready to transmit the data, they would OR this formatted command word with the desired data to transmit. This process increases transmit performance when compared to calling send functions such as DSPI_HAL_WriteDataMastermode which format the command word each time a data word is to be sent.

Parameters

| | |
|----------------|---------------------------------------|
| <i>base</i> | Module base pointer of type SPI_Type. |
| <i>command</i> | Pointer to command structure |

Returns

The command word formatted to the PUSHR data register bit field

DSPI Master Driver

16.3 DSPI Master Driver

16.3.1 Overview

This section describes the programming interface of the DSPI master mode peripheral driver. The DSPI master mode peripheral driver transfers data to and from external devices on the DSPI bus in master mode. It supports transferring data buffers with a single function call.

16.3.2 DSPI Introduction

The driver is separated into two implementations: interrupt-driven and DMA-driven. The interrupt-driven driver uses interrupts to alert the CPU that the DSPI module needs to service the SPI data transmit and receive operations. The enhanced DMA (eDMA)-driven driver uses the eDMA module to transfer data between the buffers located in memory and the DSPI module transmit/receive buffers/FIFOs. In the subsequent chapters the enhanced DMA-driven driver is referred to as the DMA-driven driver. The interrupt-driven and DMA-driven driver APIs are distinguished with the keyword "edma" in the source file name and by the keyword "Edma" in the API name. Each set of drivers have the same API functionality and are described in the following chapters. Note that the DMA driven driver also uses interrupts to alert the CPU that the DMA has completed its transfer or that one final piece of data still needs to be received which is handled by the IRQ handler in the DMA driven driver. In both the interrupt and DMA drivers, the SPI module interrupts are enabled in the NVIC. In addition, the DMA driven-driver requests channels from the eDMA module. Also, these chapters refer to either set of drivers as the "DSPI master driver" when discussing items that pertain to either driver. Note, when using the DMA driven DSPI driver, initialize the eDMA module. An example is shown in the Initialization chapter.

This is a step-by-step process to initialize and transfer the SPI data. For API specific examples, see the examples below. The example uses the interrupt-driven APIs and a blocking transfer to illustrate a high-level step-by-step usage. The usage of eDMA driver is similar to the interrupt-driven driver. Keep in mind that using interrupt and eDMA drivers in the same runtime application is not recommended because the SPI interrupt handler needs to be changed. The interrupt driver calls the [DSPI_DRV_IRQHandler\(\)](#) function and the eDMA driver calls the [DSPI_DRV_EdmaIRQHandler\(\)](#) function. See files `fsl_dspi_irq.c` and `fsl_dspi_edma_irq.c` for an example of these function calls.

```
// Initializes the DSPI
DSPI_DRV_MasterInit(masterInstance, &dspiMasterState, &userConfig);
// Configure the SPI bus
DSPI_DRV_MasterConfigureBus(masterInstance, &spiDevice, &calculatedBaudRate);
// Optional; Normally the user does not need to adjust delays, but depends on the slave device:
DSPI_DRV_MasterSetDelay(masterInstance, kDspiPcsToSck, delayInNanoSec,
    &calculatedDelay);
// Perform the transfer
DSPI_DRV_MasterTransferBlocking(masterInstance, NULL, s_dspiSourceBuffer,
    s_dspiSinkBuffer, 32, 1000);
// Do other transfers. When done with the DSPI, de-initialize to shut it down.
DSPI_DRV_MasterDeinit(masterInstance);
```

Note that it is not recommended to mix interrupt and DMA driven drivers in the same application. However, should the user decide to do so, separately set up and initialize another instance for DMA operations.

The user can also de-initialize the current interrupt-driven DSPI instance and re-initialize it for DMA operations. Note, that, because the DMA driven driver also uses interrupts, the user must direct the IRQ handler from the vector table to the desired driver's IRQ handler. See files `fsl_dspi_irq.c` and `fsl_dspi_edma_irq.c` for examples on how to re-direct the IRQ handlers from the vector table to the interrupt-driven and DMA-driven driver IRQ handlers. Such files need to be included in the application project to direct the DSPI interrupt vectors to the proper IRQ handlers. The `fsl_dspi_shared_function.c` and `fsl_dspi_edma_shared_function.c` files direct the interrupts from the vector table to the appropriate master or slave driver interrupt handler by checking the DSPI mode via the HAL function `DSPI_HAL_IsMaster(base-Addr)`. Note that the interrupt driver calls the `DSPI_DRV_IRQHandler()` function and the eDMA driver calls the `DSPI_DRV_EdmaIRQHandler()` function. See files `fsl_dspi_irq.c` and `fsl_dspi_edma_irq.c` for an example of these function calls.

When using the DSPI driver with the eDMA some DSPI instances do not support separate DMA requests for transmit and receive channels. In those cases with a single shared DMA request for transmit and receive DMA channels, the driver links one channel to the other to still take advantage of DMA transfers. However, the drawback to using an instance with shared DMA requests limits the maximum amount of data the driver can transfer. This limit depends on the bits/frame setting.

For DSPI instances with separate transmit and receive DMA requests, the maximum number of bytes that can be transferred is: 8-bit setting: 32767 bytes 16-bit setting: 65534 bytes

For DSPI instances with a shared transmit and receive DMA request, the maximum number of bytes that can be transferred is: 8-bit setting: 511 bytes 16-bit setting: 1022 bytes

See the microcontroller-specific documentation to see which DSPI instance have separate or shared transmit and receive DMA requests. Additionally, see the microcontroller-specific feature header file to see which DSPI instance have separate or shared transmit and receive DMA requests.

16.3.3 DSPI Run-time state structures

The DSPI master driver uses a run-time state structure to track the ongoing data transfers. The state structure for the interrupt-driven driver is called the `dspi_master_state_t`. The structure for the DMA driven driver is called the `dspi_edma_master_state_t`. This structure holds data that the DSPI master peripheral driver uses to communicate between the transfer function and the interrupt handler and other driver functions. The interrupt handler in the interrupt driven also uses this information to keep track of its progress. The user is only required to pass the memory for the run-time state structure. The DSPI master driver populates the members.

16.3.4 DSPI User configuration structures

The DSPI master driver uses instances of the user configuration structure for the DSPI master driver. The user configuration structure for the interrupt-driven driver is called the `dspi_master_user_config_t`. The user configuration structure for the DMA driven driver is called the `dspi_edma_master_user_config_t`. This structure allows the user to configure the most common settings of the DSPI peripheral with a single function call. The user configuration structure is passed into the master driver initialization function

DSPI Master Driver

(DSPI_DRV_MasterInit or DSPI_DRV_EdmaMasterInit). The user configuration structure consists of whichCtar (generally set this to kDspiCtar0), option for continuous clock and peripheral chip select, the desired peripheral chip select to use, and the polarity of the peripheral chip select settings. An example of this is provided in the Initialization section.

16.3.5 DSPI Device structures

The DSPI master driver uses instances of the [dspi_device_t](#) or [dspi_edma_device_t](#) structure to represent the SPI bus configuration required to communicate to an external device that is connected to the bus.

The device structure can be passed into the DSPI_DRV_MasterConfigureBus or DSPI_DRV_EdmaMasterConfigureBus functions to manually configure the bus for a particular device. For example, if there is only one device connected to the bus, the user might configure it only once. Alternatively, the device structure can be passed to the data transfer functions where the bus is reconfigured before the transfer is started. The device structure consists of bitsPerSec (baud rate in Hz) and the dataBusConfig structure which consists of bits per frame, clock polarity and phase, and data shift direction (MSB or LSB).

16.3.6 DSPI Initialization

To initialize the DSPI master driver, call the [DSPI_DRV_MasterInit\(\)](#) or the [DSPI_DRV_EdmaMasterInit](#) functions and pass the instance number of the DSPI peripheral, the memory allocation for the run-time state structure used by the master driver to keep track of data transfers, and the user configuration ([dspi_master_user_config_t](#) or [dspi_edma_master_user_config_t](#)). For the DMA driven driver, the memory allocation for the stdcSrc2CmdDataLast structure needs to be passed. Note that the pointer to this structure needs to be aligned to a 32-byte boundary.

First call the DSPI master initialization to initialize the DSPI module. Then, call the DSPI master configuration bus to configure the module for the specific device on the SPI bus. For the interrupt-driven case, while the [DSPI_DRV_MasterInit\(\)](#) function initializes the DSPI peripheral, the [DSPI_DRV_MasterConfigureBus\(\)](#) function configures the SPI bus parameters such as bits/frame, clock characteristics, data shift direction, baud rate, and desired chip select. The DMA-driven case follows the same logic, except that it uses the EDMA API names. Both examples are provided below. The interrupt driven example is provided first followed by the DMA example.

This is an example code to initialize and configure the DSPI master interrupt-driven driver including setting up the user configuration and device structures:

```
// Set up and initialize the master //
uint32_t masterInstance = 1; // example using DSPI instance 1
dspi_master_state_t dspiMasterState; // simply allocate memory for this
uint32_t calculatedBaudRate;

// configure the members of the user configuration //
dspi_master_user_config_t userConfig;
userConfig.isChipSelectContinuous = false;
userConfig.isSckContinuous = false;
userConfig.pcsPolarity = kDspiPcs_ActiveLow;
userConfig.whichCtar = kDspiCtar0;
```

```

userConfig.whichPcs = kDspiPcs1;

// Initialize the DSPI module //
DSPI_DRV_MasterInit(masterInstance, &dspiMasterState, &userConfig);

// Define the bus configuration
dspi_device_t spiDevice;
spiDevice.dataBusConfig.bitsPerFrame = 16;
spiDevice.dataBusConfig.clkPhase = kDspiClockPhase_FirstEdge;
spiDevice.dataBusConfig.clkPolarity = kDspiClockPolarity_ActiveHigh
;
spiDevice.dataBusConfig.direction = kDspiMsbFirst;
spiDevice.bitsPerSec = 500000;

// Configure the SPI bus //
DSPI_DRV_MasterConfigureBus(masterInstance, &spiDevice, &calculatedBaudRate);

```

This is an example code to initialize and configure the DSPI master DMA-driven driver including setting up the user configuration and device structures:

```

// Declare 32-byte aligned software transfer control descriptor (eDMA requirement)
// This example uses IAR preprocessor pragma syntax. Other methods also include declaring
// a 64-byte region and then aligning the pointer within that region to a 32-byte boundary,
// but this would waste 32-bytes of memory
#pragma data_alignment=32
    edma_software_tcd_t stcdTransferCntTest;

// First, initialize the eDMA peripheral driver.
// NOTE: THIS IS NOT PART OF THE DSPI DRIVER. THIS PART INITIALIZES THE EDMA DRIVER SO
// THAT THE DSPI EDMA DRIVER CAN WORK.
edma_state_t state; // <- The user allocates memory for this structure.
edma_user_config_t edmaUserConfig; // <- The user fills out members for this structure.

edmaUserConfig.chnArbitration = kEDMAChnArbitrationRoundrobin;
edmaUserConfig.notHaltOnError = false;

// Actual EDMA initialization
EDMA_DRV_Init(&state, &edmaUserConfig);

// Set up and initialize the master //
uint32_t masterInstance = 0; // example using DSPI instance 0
dspi_edma_master_state_t dspiMasterState; // simply allocate memory for this
uint32_t calculatedBaudRate;

// Configure the members of the user configuration //
dspi_edma_master_user_config_t userConfig;
userConfig.isChipSelectContinuous = false;
userConfig.isSckContinuous = false;
userConfig.pcsPolarity = kDspiPcs_ActiveLow;
userConfig.whichCtar = kDspiCtar0;
userConfig.whichPcs = kDspiPcs1;

// Initialize the DSPI module //
DSPI_DRV_EdmaMasterInit(masterInstance, &dspiMasterState, &userConfig, &
    stcdTransferCntTest);

// Define the bus configuration
dspi_edma_device_t spiDevice;
spiDevice.dataBusConfig.bitsPerFrame = 16;
spiDevice.dataBusConfig.clkPhase = kDspiClockPhase_FirstEdge;
spiDevice.dataBusConfig.clkPolarity = kDspiClockPolarity_ActiveHigh
;
spiDevice.dataBusConfig.direction = kDspiMsbFirst;
spiDevice.bitsPerSec = 500000;

```

DSPI Master Driver

```
// Configure the SPI bus //
DSPI_DRV_EdmaMasterConfigureBus(masterInstance, &spiDevice, &
    calculatedBaudRate);
```

The DSPI also offers an optional API to configure various bus timing delays. This function involves the DSPI module delay options to "fine tune" some of the signal timings and match the timing needs of a slower peripheral device. This is an optional function that can be called after the DSPI module is initialized for master mode. The bus timing delays that can be adjusted are listed here:

PCS to SCK Delay: Adjustable delay option between the assertion of the PCS signal to the first SCK edge.

After SCK Delay: Adjustable delay option between the last edge of SCK to the de-assertion of the PCS signal.

Delay after Transfer: Adjustable delay option between the de-assertion of the PCS signal for a frame to the assertion of the PCS signal for the next frame. Note that this is not adjustable for continuous clock mode because this delay is fixed at one SCK period.

This function takes in as a parameter the desired delay type and the delay value (in nanoseconds) and calculates the values needed for the prescaler and scaler. Returning the actual calculated delay as an exact delay match may not be possible. In this situation, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. In addition, the function returns an out-of-range status.

This is an example that shows how to use the set the bus timings delay function:

```
uint32_t delayInNanoSec = 200; // example, 200ns
uint32_t calculatedDelay;

// Interrupt example
// kDspiPcsToSck: PCS to SCK Delay option, delayInNanoSec is the user's passed in delay in ns
DSPI_DRV_MasterSetDelay(masterInstance, kDspiPcsToSck, delayInNanoSec,
    &calculatedDelay);

// eDMA example
// kDspiPcsToSck: PCS to SCK Delay option, delayInNanoSec is the user's passed in delay in ns
DSPI_DRV_EdmaMasterSetDelay(masterInstance,
    kDspiPcsToSck, delayInNanoSec, &calculatedDelay);
```

16.3.7 DSPI Transfers

The driver supports two different modes for transferring data: blocking and non-blocking (async). The blocking transfer function waits until the transfer is complete before returning. A timeout parameter is passed into the blocking function. A non-blocking (async) function returns immediately after starting the transfer. The user is required to get the transfer status during the transfer to ascertain when the transfer is complete. Additional functions provided to aid in non-blocking transfers are get transfer status and abort transfer. If there is a cache for memory, when using DMA to transfer data, ensure that the data is consistent. In other words, when reading the data from memory, application should ensure that the data to/from the memory device is current and is not not cached.

Blocking transfer function APIs (interrupt and DMA driven):

```

dspi_status_t DSPI_DRV_MasterTransferBlocking(uint32_t instance
,
                                     const dspi_device_t * restrict device,
                                     const uint8_t * sendBuffer,
                                     uint8_t * receiveBuffer,
                                     size_t transferByteCount,
                                     uint32_t timeout);

dspi_status_t DSPI_DRV_EdmaMasterTransferBlocking(uint32_t
instance,
                                     const dspi_edma_device_t * restrict
device,
                                     const uint8_t * sendBuffer,
                                     uint8_t * receiveBuffer,
                                     size_t transferByteCount,
                                     uint32_t timeout);

```

Non-blocking function APIs and associated functions (interrupt and DMA-driven):

```

// Interrupt-driven transfer function
dspi_status_t DSPI_DRV_MasterTransfer(uint32_t instance,
                                     const dspi_device_t * restrict device,
                                     const uint8_t * sendBuffer,
                                     uint8_t * receiveBuffer,
                                     size_t transferByteCount);

// Returns whether the previous transfer is completed (interrupt-driven )
dspi_status_t DSPI_DRV_MasterGetTransferStatus(uint32_t
instance, uint32_t * framesTransferred);

// Terminates an asynchronous transfer early (interrupt-driven )
dspi_status_t DSPI_DRV_MasterAbortTransfer(uint32_t instance);

// DMA-driven transfer function
dspi_status_t DSPI_DRV_EdmaMasterTransfer(uint32_t instance,
                                     const dspi_edma_device_t * restrict device,
                                     const uint8_t * sendBuffer,
                                     uint8_t * receiveBuffer,
                                     size_t transferByteCount);

// Returns whether the previous transfer is completed (DMA-driven)
dspi_status_t DSPI_DRV_EdmaMasterGetTransferStatus(
uint32_t instance, uint32_t * framesTransferred);

// Terminates an asynchronous transfer early (DMA-driven)
dspi_status_t DSPI_DRV_EdmaMasterAbortTransfer(uint32_t
instance);

```

Example of a blocking transfer (interrupt and DMA-driven). Note that the peripheral driver must be initialized first. See the Initialization Section for initialization information.

```

// Example blocking transfer function call (interrupt)
// Note: providing another device structure is optional and for this example, the assumption is that
// the DSPI_DRV_MasterConfigureBus was sufficient and NULL is passed for the device
// structure. Also, this example shows that 32 bytes are transferred with a timeout of 1000 µs.
DSPI_DRV_MasterTransferBlocking(masterInstance, NULL, s_dspiSourceBuffer,
s_dspiSinkBuffer, 32, 1000);

// Example blocking transfer function call (DMA)
// Note: providing another device structure is optional and for this example, the assumption is that
// the DSPI_DRV_MasterConfigureBus was sufficient and NULL is passed for the device
// structure. Also, this example shows that 32 bytes are transferred with a timeout of 1000 µs.
DSPI_DRV_EdmaMasterTransferBlocking(masterInstance, NULL,
s_dspiSourceBuffer,
s_dspiSinkBuffer, 32, 1000);

```

DSPI Master Driver

Example of a non-blocking transfer (interrupt and DMA-driven). Note that the peripheral driver must be initialized first. See the Initialization Section for initialization information.

```
// Interrupt Example
uint32_t framesXfer;
// Example non-blocking transfer function call
// Note: providing another device structure is optional and for this example, the assumption is that
// the DSPI_DRV_MasterConfigureBus was sufficient and NULL is passed for the device
// structure. Also, this example shows that 32 bytes is transferred.
DSPI_DRV_MasterTransfer(masterInstance, NULL, s_dspiSourceBuffer, s_dspiSinkBuffer,
    32);

// For non-blocking/async transfers, check back to get transfer status. For example,
// where framesXfer returns the number of frames transferred //
DSPI_DRV_MasterGetTransferStatus(masterInstance, &framesXfer);

// This is an example to terminate the on-going transfer:
DSPI_DRV_MasterAbortTransfer(masterInstance);

// DMA Example
// Example non-blocking transfer function call
// Note: providing another device structure is optional and for this example, the assumption is that
// the DSPI_DRV_MasterConfigureBus was sufficient and NULL is passed for the device
// structure. Also, this example shows that 32 bytes is transferred.
DSPI_DRV_EdmaMasterTransfer(masterInstance, NULL, s_dspiSourceBuffer,
    s_dspiSinkBuffer, 32);

// For non-blocking/async transfers, check back to get transfer status. For example,
// where framesXfer returns the number of frames transferred //
DSPI_DRV_EdmaMasterGetTransferStatus(masterInstance, &framesXfer);

// This is an example to terminate the on-going transfer:
DSPI_DRV_EdmaMasterAbortTransfer(masterInstance);
```

16.3.8 DSPI De-initialization

To deinitialize and shut down the DSPI module, call this function:

```
// interrupt-driven
void DSPI_DRV_MasterDeinit(masterInstance);

// DMA-driven
void DSPI_DRV_EdmaMasterDeinit(masterInstance);
```

Data Structures

- struct [dspi_dma_device_t](#)
Data structure containing information about a device on the SPI bus with DMA. [More...](#)
- struct [dspi_dma_master_state_t](#)
Runtime state structure for the DSPI master driver with DMA. [More...](#)
- struct [dspi_dma_master_user_config_t](#)
The user configuration structure for the DSPI master driver with DMA. [More...](#)
- struct [dspi_edma_device_t](#)
Data structure containing information about a device on the SPI bus with EDMA. [More...](#)
- struct [dspi_edma_master_state_t](#)

- *Runtime state structure for the DSPI master driver with EDMA. [More...](#)*
- struct [dspi_edma_master_user_config_t](#)
The user configuration structure for the DSPI master driver with EDMA. [More...](#)
- struct [dspi_device_t](#)
Data structure containing information about a device on the SPI bus. [More...](#)
- struct [dspi_master_state_t](#)
Runtime state structure for the DSPI master driver. [More...](#)
- struct [dspi_master_user_config_t](#)
The user configuration structure for the DSPI master driver. [More...](#)

Variables

- SPI_Type *const [g_dspiBase](#) [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type [g_dspiIrqId](#) [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.
- SPI_Type *const [g_dspiBase](#) [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type [g_dspiIrqId](#) [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.
- SPI_Type *const [g_dspiBase](#) [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type [g_dspiIrqId](#) [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.

Initialization and shutdown

- [dspi_status_t DSPI_DRV_DmaMasterInit](#) (uint32_t instance, [dspi_dma_master_state_t](#) *dspiDmaState, const [dspi_dma_master_user_config_t](#) *userConfig)
Initializes a DSPI instance for master mode operation to work with DMA.
- [dspi_status_t DSPI_DRV_DmaMasterDeinit](#) (uint32_t instance)
Shuts down a DSPI instance with the DMA support.
- [dspi_status_t DSPI_DRV_DmaMasterSetDelay](#) (uint32_t instance, [dspi_delay_type_t](#) whichDelay, uint32_t delayInNanoSec, uint32_t *calculatedDelay)
Configures the DSPI master mode bus timing delay options with the DMA support.

Bus configuration

- [dspi_status_t DSPI_DRV_DmaMasterConfigureBus](#) (uint32_t instance, const [dspi_dma_device_t](#) *device, uint32_t *calculatedBaudRate)
Configures the DSPI port physical parameters to access a device on the bus with the DMA support.

DSPI Master Driver

Blocking transfers

- [dspi_status_t DSPI_DRV_DmaMasterTransferBlocking](#) (uint32_t instance, const [dspi_dma_device_t](#) *device, const uint8_t *sendBuffer, uint8_t *receiveBuffer, size_t transferByteCount, uint32_t timeout)
Performs a blocking SPI master mode transfer with the DMA support.

Non-blocking transfers

- [dspi_status_t DSPI_DRV_DmaMasterTransfer](#) (uint32_t instance, const [dspi_dma_device_t](#) *device, const uint8_t *sendBuffer, uint8_t *receiveBuffer, size_t transferByteCount)
Performs a non-blocking SPI master mode transfer with the DMA support.
- [dspi_status_t DSPI_DRV_DmaMasterGetTransferStatus](#) (uint32_t instance, uint32_t *framesTransferred)
Returns whether the previous transfer is completed with the DMA support.
- [dspi_status_t DSPI_DRV_DmaMasterAbortTransfer](#) (uint32_t instance)
Terminates an asynchronous transfer early with the DMA support.

Initialization and shutdown

- [dspi_status_t DSPI_DRV_EdmaMasterInit](#) (uint32_t instance, [dspi_edma_master_state_t](#) *dspiEdmaState, const [dspi_edma_master_user_config_t](#) *userConfig, [edma_software_tcd_t](#) *stcdSrc2CmdDataLast)
Initializes a DSPI instance for master mode operation to work with EDMA.
- [dspi_status_t DSPI_DRV_EdmaMasterDeinit](#) (uint32_t instance)
Shuts down a DSPI instance with the EDMA support.
- [dspi_status_t DSPI_DRV_EdmaMasterSetDelay](#) (uint32_t instance, [dspi_delay_type_t](#) whichDelay, uint32_t delayInNanoSec, uint32_t *calculatedDelay)
Configures the DSPI master mode bus timing delay options with the EDMA support.

Bus configuration

- [dspi_status_t DSPI_DRV_EdmaMasterConfigureBus](#) (uint32_t instance, const [dspi_edma_device_t](#) *device, uint32_t *calculatedBaudRate)
Configures the DSPI port physical parameters to access a device on the bus with the EDMA support.

Blocking transfers

- [dspi_status_t DSPI_DRV_EdmaMasterTransferBlocking](#) (uint32_t instance, const [dspi_edma_device_t](#) *device, const uint8_t *sendBuffer, uint8_t *receiveBuffer, size_t transferByteCount, uint32_t timeout)
Performs a blocking SPI master mode transfer with the EDMA support.

Non-blocking transfers

- `dspi_status_t DSPI_DRV_EdmaMasterTransfer` (`uint32_t` instance, `const dspi_edma_device_t *device`, `const uint8_t *sendBuffer`, `uint8_t *receiveBuffer`, `size_t transferByteCount`)
Performs a non-blocking SPI master mode transfer with the EDMA support.
- `dspi_status_t DSPI_DRV_EdmaMasterGetTransferStatus` (`uint32_t` instance, `uint32_t *frames-Transferred`)
Returns whether the previous transfer is completed with the EDMA support.
- `dspi_status_t DSPI_DRV_EdmaMasterAbortTransfer` (`uint32_t` instance)
Terminates an asynchronous transfer early with the EDMA support.
- `void DSPI_DRV_EdmaMasterIRQHandler` (`uint32_t` instance)
Interrupt handler for DSPI master mode.

Initialization and shutdown

- `dspi_status_t DSPI_DRV_MasterInit` (`uint32_t` instance, `dspi_master_state_t *dspiState`, `const dspi-_master_user_config_t *userConfig`)
Initializes a DSPI instance for master mode operation.
- `dspi_status_t DSPI_DRV_MasterDeinit` (`uint32_t` instance)
Shuts down a DSPI instance.
- `dspi_status_t DSPI_DRV_MasterSetDelay` (`uint32_t` instance, `dspi_delay_type_t whichDelay`, `uint32_t delayInNanoSec`, `uint32_t *calculatedDelay`)
Configures the DSPI master mode bus timing delay options.

Bus configuration

- `dspi_status_t DSPI_DRV_MasterConfigureBus` (`uint32_t` instance, `const dspi_device_t *device`, `uint32_t *calculatedBaudRate`)
Configures the DSPI port physical parameters to access a device on the bus.

Blocking transfers

- `dspi_status_t DSPI_DRV_MasterTransferBlocking` (`uint32_t` instance, `const dspi_device_t *device`, `const uint8_t *sendBuffer`, `uint8_t *receiveBuffer`, `size_t transferByteCount`, `uint32_t timeout`)
Performs a blocking SPI master mode transfer.

Non-blocking transfers

- `dspi_status_t DSPI_DRV_MasterTransfer` (`uint32_t` instance, `const dspi_device_t *device`, `const uint8_t *sendBuffer`, `uint8_t *receiveBuffer`, `size_t transferByteCount`)
Performs a non-blocking SPI master mode transfer.
- `dspi_status_t DSPI_DRV_MasterGetTransferStatus` (`uint32_t` instance, `uint32_t *frames-Transferred`)
Returns whether the previous transfer is completed.

DSPI Master Driver

- [dspi_status_t DSPI_DRV_MasterAbortTransfer](#) (uint32_t instance)
Terminates an asynchronous transfer early.
- void [DSPI_DRV_MasterIRQHandler](#) (uint32_t instance)
Interrupt handler for DSPI master mode.

16.3.9 Data Structure Documentation

16.3.9.1 struct dspi_dma_device_t

The user must populate the members to set up the DSPI master with DMA and properly communicate with the SPI device.

Data Fields

- uint32_t [bitsPerSec](#)
Baud rate in bits per second.

16.3.9.1.0.81 Field Documentation

16.3.9.1.0.81.1 uint32_t dspi_dma_device_t::bitsPerSec

16.3.9.2 struct dspi_dma_master_state_t

This structure holds data used by the DSPI master Peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. The user passes the memory for this run-time state structure. The DSPI master driver populates the members.

Data Fields

- [dspi_ctar_selection_t whichCtar](#)
Desired Clock and Transfer Attributes Register (CTAR)
- uint32_t [bitsPerFrame](#)
Desired number of bits per frame.
- [dspi_which_pcs_config_t whichPcs](#)
Desired Peripheral Chip Select (pcs)
- bool [isChipSelectContinuous](#)
Option to enable the continuous assertion of chip select between transfers.
- uint32_t [dspiSourceClock](#)
Module source clock.
- volatile bool [isTransferInProgress](#)
True if there is an active transfer.
- volatile bool [isTransferBlocking](#)
True if transfer is a blocking transaction.
- [semaphore_t irqSync](#)
Used to wait for ISR to complete its business.
- [dma_channel_t dmaTxDataChannel](#)

- *Structure definition for the DMA channel.*
[dma_channel_t dmaTxCmdChannel](#)
- *Structure definition for the DMA channel.*
[dma_channel_t dmaRxChannel](#)
- *Structure definition for the DMA channel.*
 bool [extraByte](#)
Flag used for 16-bit transfers with odd byte count.
- [uint8_t * rxBuffer](#)
The buffer into which received bytes are placed.
- [uint32_t rxTransferByteCnt](#)
Number of bytes to receive.

16.3.9.2.0.82 Field Documentation

16.3.9.2.0.82.1 volatile bool [dspi_dma_master_state_t::isTransferInProgress](#)

16.3.9.2.0.82.2 volatile bool [dspi_dma_master_state_t::isTransferBlocking](#)

16.3.9.2.0.82.3 semaphore_t [dspi_dma_master_state_t::irqSync](#)

16.3.9.2.0.82.4 uint8_t* [dspi_dma_master_state_t::rxBuffer](#)

16.3.9.2.0.82.5 uint32_t [dspi_dma_master_state_t::rxTransferByteCnt](#)

16.3.9.3 struct [dspi_dma_master_user_config_t](#)

Use an instance of this structure with the [DSPI_DRV_DmaMasterInit\(\)](#) function. This allows the user to configure the most common settings of the DSPI peripheral with a single function call.

Data Fields

- [dspi_ctar_selection_t whichCtar](#)
Desired Clock and Transfer Attributes Register(CTAR)
- bool [isSckContinuous](#)
Disable or Enable continuous SCK operation.
- bool [isChipSelectContinuous](#)
Option to enable the continuous assertion of chip select between transfers.
- [dspi_which_pcs_config_t whichPcs](#)
Desired Peripheral Chip Select (pcs)
- [dspi_pcs_polarity_config_t pcsPolarity](#)
Peripheral Chip Select (pcs) polarity setting.

16.3.9.3.0.83 Field Documentation

16.3.9.3.0.83.1 [dspi_pcs_polarity_config_t dspi_dma_master_user_config_t::pcsPolarity](#)

16.3.9.4 struct [dspi_edma_device_t](#)

The user must populate the members to set up the DSPI master with EDMA and properly communicate with the SPI device.

DSPI Master Driver

Data Fields

- `uint32_t bitsPerSec`
Baud rate in bits per second.

16.3.9.4.0.84 Field Documentation

16.3.9.4.0.84.1 `uint32_t dsp_i_edma_device_t::bitsPerSec`

16.3.9.5 `struct dsp_i_edma_master_state_t`

This structure holds data used by the DSPI master Peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. The user passes the memory for this run-time state structure. The DSPI master driver populates the members.

Data Fields

- `dspi_ctar_selection_t whichCtar`
Desired Clock and Transfer Attributes Register (CTAR)
- `uint32_t bitsPerFrame`
Desired number of bits per frame.
- `dspi_which_pcs_config_t whichPcs`
Desired Peripheral Chip Select (pcs)
- `bool isChipSelectContinuous`
Option to enable the continuous assertion of chip select between transfers.
- `uint32_t dsp_i_sourceClock`
Module source clock.
- `volatile bool isTransferInProgress`
True if there is an active transfer.
- `volatile bool isTransferBlocking`
True if transfer is a blocking transaction.
- `semaphore_t irqSync`
Used to wait for ISR to complete its business.
- `edma_chn_state_t dmaCmdData2Fifo`
Structure definition for the eDMA channel.
- `edma_chn_state_t dmaSrc2CmdData`
Structure definition for the eDMA channel.
- `edma_chn_state_t dmaFifo2Receive`
Structure definition for the eDMA channel.
- `edma_software_tcd_t * stcdSrc2CmdDataLast`
Pointer to SW TCD in memory.
- `bool extraByte`
Flag used for 16-bit transfers with odd byte count.
- `uint8_t * rxBuffer`
The buffer into which received bytes are placed.
- `uint32_t rxTransferByteCnt`
Number of bytes to receive.

16.3.9.5.0.85 Field Documentation**16.3.9.5.0.85.1** `volatile bool dsp_i_edma_master_state_t::isTransferInProgress`**16.3.9.5.0.85.2** `volatile bool dsp_i_edma_master_state_t::isTransferBlocking`**16.3.9.5.0.85.3** `semaphore_t dsp_i_edma_master_state_t::irqSync`**16.3.9.5.0.85.4** `uint8_t* dsp_i_edma_master_state_t::rxBuffer`**16.3.9.5.0.85.5** `uint32_t dsp_i_edma_master_state_t::rxTransferByteCnt`**16.3.9.6 struct dsp_i_edma_master_user_config_t**

Use an instance of this structure with the `DSPI_DRV_EdmaMasterInit()` function. This allows the user to configure the most common settings of the DSPI peripheral with a single function call.

Data Fields

- `dsp_i_ctar_selection_t whichCtar`
Desired Clock and Transfer Attributes Register(CTAR)
- `bool isSckContinuous`
Disable or Enable continuous SCK operation.
- `bool isChipSelectContinuous`
Option to enable the continuous assertion of chip select between transfers.
- `dsp_i_which_pcs_config_t whichPcs`
Desired Peripheral Chip Select (pcs)
- `dsp_i_pcs_polarity_config_t pcsPolarity`
Peripheral Chip Select (pcs) polarity setting.

16.3.9.6.0.86 Field Documentation**16.3.9.6.0.86.1** `dsp_i_pcs_polarity_config_t dsp_i_edma_master_user_config_t::pcsPolarity`**16.3.9.7 struct dsp_i_device_t**

The user must populate these members to set up the DSPI master and properly communicate with the SPI device.

Data Fields

- `uint32_t bitsPerSec`
Baud rate in bits per second.

DSPI Master Driver

16.3.9.7.0.87 Field Documentation

16.3.9.7.0.87.1 uint32_t dspi_device_t::bitsPerSec

16.3.9.8 struct dspi_master_state_t

This structure holds data that is used by the DSPI master peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. The user must pass the memory for this run-time state structure. The DSPI master driver populates the members.

Data Fields

- [dspi_ctar_selection_t](#) [whichCtar](#)
Desired Clock and Transfer Attributes Register (CTAR)
- uint32_t [bitsPerFrame](#)
Desired number of bits per frame.
- [dspi_which_pcs_config_t](#) [whichPcs](#)
Desired Peripheral Chip Select (pcs)
- bool [isChipSelectContinuous](#)
Option to enable the continuous assertion of chip select between transfers.
- uint32_t [dspiSourceClock](#)
Module source clock.
- volatile bool [isTransferInProgress](#)
True if there is an active transfer.
- const uint8_t * [sendBuffer](#)
The buffer from which transmitted bytes are taken.
- uint8_t * [receiveBuffer](#)
The buffer into which received bytes are placed.
- volatile size_t [remainingSendByteCount](#)
Number of bytes remaining to send.
- volatile size_t [remainingReceiveByteCount](#)
Number of bytes remaining to receive.
- volatile bool [isTransferBlocking](#)
True if transfer is a blocking transaction.
- [semaphore_t](#) [irqSync](#)
Used to wait for ISR to complete its business.
- bool [extraByte](#)
Flag used for 16-bit transfers with odd byte count.

16.3.9.8.0.88 Field Documentation

- 16.3.9.8.0.88.1 `volatile bool dsp_i_master_state_t::isTransferInProgress`
- 16.3.9.8.0.88.2 `const uint8_t* dsp_i_master_state_t::sendBuffer`
- 16.3.9.8.0.88.3 `uint8_t* dsp_i_master_state_t::receiveBuffer`
- 16.3.9.8.0.88.4 `volatile size_t dsp_i_master_state_t::remainingSendByteCount`
- 16.3.9.8.0.88.5 `volatile size_t dsp_i_master_state_t::remainingReceiveByteCount`

- 16.3.9.8.0.88.7 `semaphore_t dsp_i_master_state_t::irqSync`

16.3.9.9 struct `dspi_master_user_config_t`

Use an instance of this structure with the `DSPI_DRV_MasterInit()` function. This allows the user to configure the most common settings of the DSPI peripheral with a single function call.

Data Fields

- `dspi_ctar_selection_t whichCtar`
Desired Clock and Transfer Attributes Register (CTAR)
- `bool isSckContinuous`
Disable or Enable continuous SCK operation.
- `bool isChipSelectContinuous`
Option to enable the continuous assertion of chip select between transfers.
- `dspi_which_pcs_config_t whichPcs`
Desired Peripheral Chip Select (pcs)
- `dspi_pcs_polarity_config_t pcsPolarity`
Peripheral Chip Select (pcs) polarity setting.

16.3.10 Function Documentation

- 16.3.10.1 `dspi_status_t DSPI_DRV_DmaMasterInit (uint32_t instance, dsp_i_dma_master_state_t * dsp_iDmaState, const dsp_i_dma_master_user_config_t * userConfig)`

This function uses a DMA-driven method for transferring data. This function initializes the run-time state structure to track the ongoing transfers, ungates the clock to the DSPI module, resets the DSPI module, initializes the module to user-defined settings and default settings, configures the IRQ state structure, enables the module-level interrupt to the core, and enables the DSPI module. The CTAR parameter is special in that it allows the user to have different SPI devices connected to the same DSPI module instance in addition to different peripheral chip selects. Each CTAR contains the bus attributes associated with that particular SPI device. For most use cases, where only one SPI device is connected per DSPI module

DSPI Master Driver

instance, use CTAR0. This is an example to set up and call the DSPI_DRV_DmaMasterInit function by passing in these parameters:

```
dspi_dma_master_state_t dspiDmaState; <- the user allocates memory for this
    structure
uint32_t calculatedBaudRate;
dspi_dma_master_user_config_t userConfig; <- the user populates members for
    this structure
userConfig.isChipSelectContinuous = false;
userConfig.isSckContinuous = false;
userConfig.pcsPolarity = kDspiPcs_ActiveLow;
userConfig.whichCtar = kDspiCtar0;
userConfig.whichPcs = kDspiPcs0;
DSPI_DRV_DmaMasterInit(masterInstance, &dspiDmaState, &userConfig);
```

Parameters

| | |
|-----------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiDmaState</i> | The pointer to the DSPI DMA master driver state structure. The user passes the memory for the run-time state structure. The DSPI master driver populates the members. The run-time state structure keeps track of the transfer in progress. |
| <i>userConfig</i> | The <code>dspi_dma_master_user_config_t</code> user configuration structure. The user populates the members of this structure and passes the pointer of the structure into the function. |
| <i>stcdSrc2Cmd-DataLast</i> | This is a pointer to a structure of the <code>stcdSrc2CmdDataLast</code> type. It needs to be aligned to a 32-byte boundary. Some compilers allow you to use a <code>#pragma</code> directive to align a variable to a desired boundary. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.2 dspi_status_t DSPI_DRV_DmaMasterDeinit (uint32_t instance)

This function resets the DSPI peripheral, gates its clock, disables any used interrupts to the core, and releases any used DMA channels.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization

16.3.10.3 dspi_status_t DSPI_DRV_DmaMasterSetDelay (uint32_t *instance*, dspi_delay_type_t *whichDelay*, uint32_t *delayInNanoSec*, uint32_t * *calculatedDelay*)

This function uses the DSPI module delay options to "fine tune" some of the signal timings and match the timing needs of a slower peripheral device. This is an optional function that can be called after the DSPI module has been initialized for master mode. The bus timing delays that can be adjusted are listed below:

PCS to SCK Delay: Adjustable delay option between the assertion of the PCS signal to the first SCK edge.

After SCK Delay: Adjustable delay option between the last edge of SCK to the de-assertion of the PCS signal.

Delay after Transfer: Adjustable delay option between the de-assertion of the PCS signal for a frame to the assertion of the PCS signal for the next frame. Note that this is not adjustable for continuous clock mode because this delay is fixed at one SCK period.

Each of the above delay parameters use both a pre-scalar and scalar value to calculate the needed delay. This function takes in as a parameter the desired delay type and the delay value (in nanoseconds), calculates the values needed for the prescaler and scaler. Returning the actual calculated delay as an exact delay match may not be possible. In this case, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. In addition, the function returns an out-of-range status.

Parameters

| | |
|------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>whichDelay</i> | The desired delay to configure, must be of type dspi_delay_type_t |
| <i>delayInNanoSec</i> | The desired delay value in nano-seconds. |
| <i>calculatedDelay</i> | The calculated delay that best matches the desired delay (in nano-seconds). |

Returns

Either kStatus_DSPI_Success or kStatus_DSPI_OutOfRange if the desired delay exceeds the capability of the device.

16.3.10.4 dspi_status_t DSPI_DRV_DmaMasterConfigureBus (uint32_t *instance*, const dspi_dma_device_t * *device*, uint32_t * *calculatedBaudRate*)

The term "device" is used to indicate the SPI device for which the DSPI master is communicating. The user has two options to configure the device parameters: pass in the pointer to the device configuration structure to the desired transfer function (see DSPI_DRV_DmaMasterTransferBlocking or DSPI_DRV_DmaMasterTransfer) or pass it in to the DSPI_DRV_DmaMasterConfigureBus function. The user can

DSPI Master Driver

pass in a device structure to the transfer function which contains the parameters for the bus (the transfer function then calls this function). However, the user has the option to call this function directly especially to get the calculated baud rate, at which point they may pass in NULL for the device structure in the transfer function (assuming they have called this configure bus function first). This is an example to set up the `dspi_device_t` structure to call the `DSPI_DRV_DmaMasterConfigureBus` function by passing in these parameters:

```
dspi_dma_device_t spiDevice;
spiDevice.dataBusConfig.bitsPerFrame = 16;
spiDevice.dataBusConfig.clkPhase = kDspiClockPhase_FirstEdge;
spiDevice.dataBusConfig.clkPolarity = kDspiClockPolarity_ActiveHigh
;
spiDevice.dataBusConfig.direction = kDspiMsbFirst;
spiDevice.bitsPerSec = 50000;
DSPI_DRV_DmaMasterConfigureBus(instance, &spiDevice, &calculatedBaudRate);
```

Parameters

| | |
|----------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration. The device parameters are the desired baud rate (in bits-per-sec), and the data format field which consists of bits-per-frame, clock polarity and phase, and data shift direction. |
| <i>calculated-BaudRate</i> | The calculated baud rate passed back to the user to determine if the calculated baud rate is close enough to meet the needs. The baud rate never exceeds the desired baud rate. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.5 `dspi_status_t DSPI_DRV_DmaMasterTransferBlocking (uint32_t instance, const dspi_dma_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount, uint32_t timeout)`

This function simultaneously sends and receives data on the SPI bus, because the SPI is naturally a full-duplex bus. The function does not return until the transfer is complete.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the DSPI_DRV_DmaMasterConfigureBus function. |
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter and bytes with a value of 0 (zero) is sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |
| <i>timeout</i> | A timeout for the transfer in milliseconds. If the transfer takes longer than this amount of time, the transfer is aborted and a kStatus_SPI_Timeout error returned. |

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_Busy Cannot perform transfer because a transfer is already in progress, or kStatus_DSPI_Timeout The transfer timed out and was aborted.

16.3.10.6 `dspi_status_t DSPI_DRV_DmaMasterTransfer (uint32_t instance, const dspi_dma_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount)`

This function returns immediately. The user must check back whether the transfer is complete (using the DSPI_DRV_DmaMasterGetTransferStatus function). This function simultaneously sends and receives data on the SPI bus because the SPI is a full-duplex bus.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the DSPI_DRV_DmaMasterConfigureBus function. |

DSPI Master Driver

| | |
|---------------------------|--|
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter, in which case bytes with a value of 0 (zero) are sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_Busy Cannot perform transfer because a transfer is already in progress.

16.3.10.7 dspi_status_t DSPI_DRV_DmaMasterGetTransferStatus (uint32_t instance, uint32_t * framesTransferred)

When performing an a-sync transfer, the user can call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to now.

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value populated with the number of frames that have been sent during the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. framesTransferred is filled with the number of words that have been transferred so far.

16.3.10.8 dspi_status_t DSPI_DRV_DmaMasterAbortTransfer (uint32_t instance)

During an a-sync transfer, the user has the option to terminate the transfer early if the transfer is still in progress.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_NoTransferInProgress No transfer is currently in progress.

**16.3.10.9 dspi_status_t DSPI_DRV_EdmaMasterInit (uint32_t instance, dspi_edma-
_master_state_t * dspiEdmaState, const dspi_edma_master_user_config_t *
userConfig, edma_software_tcd_t * stcdSrc2CmdDataLast)**

This function uses a DMA-driven method for transferring data. This function initializes the run-time state structure to track the ongoing transfers, ungates the clock to the DSPI module, resets the DSPI module, initializes the module to user-defined settings and default settings, configures the IRQ state structure, enables the module-level interrupt to the core, and enables the DSPI module. The CTAR parameter is special in that it allows the user to have different SPI devices connected to the same DSPI module instance in addition to different peripheral chip selects. Each CTAR contains the bus attributes associated with that particular SPI device. For most use cases, where only one SPI device is connected per DSPI module instance, use CTAR0. This is an example to set up and call the DSPI_DRV_EdmaMasterInit function by passing in these parameters:

```
dspi_edma_master_state_t dspiEdmaState; <- the user allocates memory for this
    structure
uint32_t calculatedBaudRate;
dspi_edma_master_user_config_t userConfig; <- the user populates members for
    this structure
userConfig.isChipSelectContinuous = false;
userConfig.isSckContinuous = false;
userConfig.pcsPolarity = kDspiPcs_ActiveLow;
userConfig.whichCtar = kDspiCtar0;
userConfig.whichPcs = kDspiPcs0;
DSPI_DRV_EdmaMasterInit(masterInstance, &dspiEdmaState, &userConfig);
```

Parameters

| | |
|----------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiEdmaState</i> | The pointer to the DSPI EDMA master driver state structure. The user passes the memory for the run-time state structure. The DSPI master driver populates the members. The run-time state structure keeps track of the transfer in progress. |

DSPI Master Driver

| | |
|-----------------------------|--|
| <i>userConfig</i> | The <code>dspi_edma_master_user_config_t</code> user configuration structure. The user populates the members of this structure and passes the pointer of the structure into the function. |
| <i>stcdSrc2Cmd-DataLast</i> | This is a pointer to a structure of the <code>stcdSrc2CmdDataLast</code> type. It needs to be aligned to a 32-byte boundary. Some compilers allow you to use a <code>#pragma</code> directive to align a variable to a desired boundary. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.10 `dspi_status_t DSPI_DRV_EdmaMasterDeinit (uint32_t instance)`

This function resets the DSPI peripheral, gates its clock, disables any used interrupts to the core, and releases any used DMA channels.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization

16.3.10.11 `dspi_status_t DSPI_DRV_EdmaMasterSetDelay (uint32_t instance, dspi_delay_type_t whichDelay, uint32_t delayInNanoSec, uint32_t * calculatedDelay)`

This function uses the DSPI module delay options to "fine tune" some of the signal timings and match the timing needs of a slower peripheral device. This is an optional function that can be called after the DSPI module has been initialized for master mode. The bus timing delays that can be adjusted are listed below:

PCS to SCK Delay: Adjustable delay option between the assertion of the PCS signal to the first SCK edge.

After SCK Delay: Adjustable delay option between the last edge of SCK to the de-assertion of the PCS signal.

Delay after Transfer: Adjustable delay option between the de-assertion of the PCS signal for a frame to the assertion of the PCS signal for the next frame. Note that this is not adjustable for continuous clock mode because this delay is fixed at one SCK period.

Each of the above delay parameters uses both a pre-scalar and scalar value to calculate the needed delay. This function takes the desired delay type as a parameter and the delay value (in nanoseconds), calculates the values needed for the prescaler and scalar. Returning the actual calculated delay as an exact delay

match may not be possible. In this situation, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. In addition, the function returns an out-of-range status.

Parameters

| | |
|-------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>whichDelay</i> | The desired delay to configure, must be of type <code>dspi_delay_type_t</code> |
| <i>delayInNanoSec</i> | The desired delay value in nanoseconds. |
| <i>calculated-Delay</i> | The calculated delay that best matches the desired delay (in nanoseconds). |

Returns

Either `kStatus_DSPI_Success` or `kStatus_DSPI_OutOfRange` if the desired delay exceeds the capability of the device.

16.3.10.12 `dspi_status_t DSPI_DRV_EdmaMasterConfigureBus (uint32_t instance, const dspi_edma_device_t * device, uint32_t * calculatedBaudRate)`

The term "device" describes the SPI device for which the DSPI master is communicating. The user has two options to configure the device parameters: pass in the pointer to the device configuration structure to the desired transfer function (see `DSPI_DRV_EdmaMasterTransferBlocking` or `DSPI_DRV_EdmaMasterTransfer`) or pass it in to the `DSPI_DRV_EdmaMasterConfigureBus` function. The user can pass in a device structure to the transfer function which contains the parameters for the bus (the transfer function then calls this function). However, the user has the option to call this function directly to get the calculated baud rate, at which point, the user may pass in `NULL` for the device structure in the transfer function (assuming they have called this configure bus function first). This is an example to set up the `dspi_device_t` structure to call the `DSPI_DRV_EdmaMasterConfigureBus` function by passing in these parameters:

```
dspi_edma_device_t spiDevice;
spiDevice.dataBusConfig.bitsPerFrame = 16;
spiDevice.dataBusConfig.clkPhase = kDspiClockPhase_FirstEdge;
spiDevice.dataBusConfig.clkPolarity = kDspiClockPolarity_ActiveHigh
;
spiDevice.dataBusConfig.direction = kDspiMsbFirst;
spiDevice.bitsPerSec = 50000;
DSPI_DRV_EdmaMasterConfigureBus(instance, &spiDevice, &calculatedBaudRate);
```

DSPI Master Driver

Parameters

| | |
|----------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration. The device parameters are the desired baud rate (in bits-per-sec), and the data format field which consists of bits-per-frame, clock polarity and phase, and data shift direction. |
| <i>calculated-BaudRate</i> | The calculated baud rate passed back to the user to determine if the calculated baud rate is close enough to meet the needs. The baud rate never exceeds the desired baud rate. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.13 `dspi_status_t DSPI_DRV_EdmaMasterTransferBlocking (uint32_t instance, const dspi_edma_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount, uint32_t timeout)`

This function simultaneously sends and receives data on the SPI bus, because the SPI is naturally a full-duplex bus. The function does not return until the transfer is complete.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the <code>DSPI_DRV_EdmaMasterConfigureBus</code> function. |
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter and bytes with a value of 0 (zero) is sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

| | |
|----------------|---|
| <i>timeout</i> | A timeout for the transfer in milliseconds. If the transfer takes longer than this amount of time, the transfer is aborted and a <code>kStatus_SPI_Timeout</code> error returned. |
|----------------|---|

Returns

`kStatus_DSPI_Success` The transfer was successful, or `kStatus_DSPI_Busy` Cannot perform transfer because a transfer is already in progress, or `kStatus_DSPI_Timeout` The transfer timed out and was aborted.

16.3.10.14 `dspi_status_t DSPI_DRV_EdmaMasterTransfer (uint32_t instance, const dspi_edma_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount)`

This function returns immediately. The user must check back whether the transfer is complete (using the `DSPI_DRV_EdmaMasterGetTransferStatus` function). This function simultaneously sends and receives data on the SPI bus because the SPI is a full-duplex bus.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the <code>DSPI_DRV_EdmaMasterConfigureBus</code> function. |
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter, in which case bytes with a value of 0 (zero) are sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

`kStatus_DSPI_Success` The transfer was successful, or `kStatus_DSPI_Busy` Cannot perform transfer because a transfer is already in progress.

16.3.10.15 `dspi_status_t DSPI_DRV_EdmaMasterGetTransferStatus (uint32_t instance, uint32_t * framesTransferred)`

When performing an a-sync transfer, the user can call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to now.

DSPI Master Driver

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value populated with the number of frames that have been sent during the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. framesTransferred is filled with the number of words that have been transferred so far.

16.3.10.16 `dspi_status_t DSPI_DRV_EdmaMasterAbortTransfer (uint32_t instance)`

During an a-sync transfer, the user has the option to terminate the transfer early if the transfer is still in progress.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_NoTransferInProgress No transfer is currently in progress.

16.3.10.17 `void DSPI_DRV_EdmaMasterIRQHandler (uint32_t instance)`

This handler uses the buffers stored in the [dspi_master_state_t](#) structures to transfer data.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

16.3.10.18 `dspi_status_t DSPI_DRV_MasterInit (uint32_t instance, dspi_master_state_t * dspState, const dspi_master_user_config_t * userConfig)`

This function uses a CPU interrupt driven method for transferring data. This function initializes the run-time state structure to track the ongoing transfers, un-gates the clock to the DSPI module, resets the DSPI module, initializes the module to user defined settings and default settings, configures the IRQ state structure, enables the module-level interrupt to the core, and enables the DSPI module. The CTAR

parameter is special in that it allows the user to have different SPI devices connected to the same DSPI module instance in addition to different peripheral device selects. Each CTAR contains the bus attributes associated with that particular SPI device. For most use cases where only one SPI device is connected per DSPI module instance, use CTAR0. This is an example to set up the `dspi_master_state_t` and the `dspi_master_user_config_t` parameters and to call the `DSPI_DRV_MasterInit` function by passing in these parameters:

```
dspi_master_state_t dspiMasterState; <- the user allocates memory for this structure
uint32_t calculatedBaudRate;
dspi_master_user_config_t userConfig; <- the user populates members for this
    structure
userConfig.isChipSelectContinuous = false;
userConfig.isSckContinuous = false;
userConfig.pcsPolarity = kDspiPcs_ActiveLow;
userConfig.whichCtar = kDspiCtar0;
userConfig.whichPcs = kDspiPcs0;
DSPI_DRV_MasterInit(masterInstance, &dspiMasterState, &userConfig);
```

Parameters

| | |
|-------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiState</i> | The pointer to the DSPI master driver state structure. The user passes the memory for this run-time state structure. The DSPI master driver populates the members. This run-time state structure keeps track of the transfer in progress. |
| <i>userConfig</i> | The <code>dspi_master_user_config_t</code> user configuration structure. The user populates the members of this structure and passes the pointer of this structure to the function. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.19 dspi_status_t DSPI_DRV_MasterDeinit (uint32_t instance)

This function resets the DSPI peripheral, gates its clock, and disables the interrupt to the core.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization

DSPI Master Driver

16.3.10.20 `dspi_status_t DSPI_DRV_MasterSetDelay (uint32_t instance, dspi_delay_type_t whichDelay, uint32_t delayInNanoSec, uint32_t * calculatedDelay)`

This function involves the DSPI module's delay options to "fine tune" some of the signal timings and match the timing needs of a slower peripheral device. This is an optional function that can be called after the DSPI module has been initialized for master mode. The bus timing delays that can be adjusted are listed below:

PCS to SCK Delay: Adjustable delay option between the assertion of the PCS signal to the first SCK edge.

After SCK Delay: Adjustable delay option between the last edge of SCK to the de-assertion of the PCS signal.

Delay after Transfer: Adjustable delay option between the de-assertion of the PCS signal for a frame to the assertion of the PCS signal for the next frame. Note that this is not adjustable for continuous clock mode because this delay is fixed at one SCK period.

Each of the above delay parameters use both a pre-scalar and scalar value to calculate the needed delay. This function takes in as a parameter the desired delay type and the delay value (in nanoseconds), calculates the values needed for the prescaler and scaler. Returning the actual calculated delay as an exact delay match may not be possible. In this case, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. In addition, the function returns an out-of-range status.

Parameters

| | |
|-------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>whichDelay</i> | The desired delay to configure, must be of type <code>dspi_delay_type_t</code> |
| <i>delayInNanoSec</i> | The desired delay value in nanoseconds. |
| <i>calculated-Delay</i> | The calculated delay that best matches the desired delay (in nanoseconds). |

Returns

Either `kStatus_DSPI_Success` or `kStatus_DSPI_OutOfRange` if the desired delay exceeds the capability of the device.

16.3.10.21 `dspi_status_t DSPI_DRV_MasterConfigureBus (uint32_t instance, const dspi_device_t * device, uint32_t * calculatedBaudRate)`

The term "device" is used to indicate the SPI device for which the DSPI master is communicating. The user has two options to configure the device parameters: either pass in the pointer to the device configuration structure to the desired transfer function (see `DSPI_DRV_MasterTransferBlocking` or `DSPI_DR-`

V_MasterTransfer) or pass it in to the DSPI_DRV_MasterConfigureBus function. The user can pass in a device structure to the transfer function which contains the parameters for the bus (the transfer function then calls this function). However, the user has the option to call this function directly especially to get the calculated baud rate, at which point they may pass in NULL for the device structure in the transfer function (assuming they have called this configure bus function first). This is an example to set up the `dspi_device_t` structure to call the DSPI_DRV_MasterConfigureBus function by passing in these parameters:

```
dspi_device_t spiDevice;
spiDevice.dataBusConfig.bitsPerFrame = 16;
spiDevice.dataBusConfig.clkPhase = kDspiClockPhase_FirstEdge;
spiDevice.dataBusConfig.clkPolarity = kDspiClockPolarity_ActiveHigh
;
spiDevice.dataBusConfig.direction = kDspiMsbFirst;
spiDevice.bitsPerSec = 50000;
DSPI_DRV_MasterConfigureBus(instance, &spiDevice, &calculatedBaudRate);
```

Parameters

| | |
|----------------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration. The device parameters are the desired baud rate (in bits-per-sec), and the data format field which consists of bits-per-frame, clock polarity and phase, and data shift direction. |
| <i>calculated-BaudRate</i> | The calculated baud rate passed back to the user to determine if the calculated baud rate is close enough to meet the needs. The baud rate never exceeds the desired baud rate. |

Returns

An error code or `kStatus_DSPI_Success`.

16.3.10.22 `dspi_status_t DSPI_DRV_MasterTransferBlocking (uint32_t instance, const dspi_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount, uint32_t timeout)`

This function simultaneously sends and receives data on the SPI bus, as SPI is naturally a full-duplex bus. The function does not return until the transfer is complete.

Parameters

DSPI Master Driver

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the DSPI_DRV_MasterConfigureBus function. |
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter and bytes with a value of 0 (zero) is sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |
| <i>timeout</i> | A timeout for the transfer in milliseconds. If the transfer takes longer than this amount of time, the transfer is aborted and a kStatus_SPI_Timeout error returned. |

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_Busy Cannot perform transfer because a transfer is already in progress, or kStatus_DSPI_Timeout The transfer timed out and was aborted.

16.3.10.23 dspi_status_t DSPI_DRV_MasterTransfer (uint32_t instance, const dspi_device_t * device, const uint8_t * sendBuffer, uint8_t * receiveBuffer, size_t transferByteCount)

This function returns immediately. The user needs to check whether the transfer is complete using the DSPI_DRV_MasterGetTransferStatus function. This function simultaneously sends and receives data on the SPI bus because the SPI is naturally a full-duplex bus.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>device</i> | Pointer to the device information structure. This structure contains the settings for the SPI bus configuration in this transfer. You may pass NULL for this parameter, in which case the current bus configuration is used unmodified. The device can be configured separately by calling the DSPI_DRV_MasterConfigureBus function. |

| | |
|---------------------------|--|
| <i>sendBuffer</i> | The pointer to the data buffer of the data to send. You may pass NULL for this parameter, in which case bytes with a value of 0 (zero) are sent. |
| <i>receiveBuffer</i> | Pointer to the buffer where the received bytes are stored. If you pass NULL for this parameter, the received bytes are ignored. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_Busy Cannot perform transfer because a transfer is already in progress.

16.3.10.24 **dspi_status_t DSPI_DRV_MasterGetTransferStatus (uint32_t instance, uint32_t * framesTransferred)**

When performing an a-sync transfer, the user can call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to now.

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value that is filled in with the number of frames that have been sent in the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. framesTransferred is filled with the number of words that have been transferred so far.

16.3.10.25 **dspi_status_t DSPI_DRV_MasterAbortTransfer (uint32_t instance)**

During an a-sync transfer, the user has the option to terminate the transfer early if the transfer is still in progress.

DSPI Master Driver

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

kStatus_DSPI_Success The transfer was successful, or kStatus_DSPI_NoTransferInProgress No transfer is currently in progress.

16.3.10.26 void DSPI_DRV_MasterIRQHandler (uint32_t *instance*)

This handler uses the buffers stored in the [dspirqlid](#) structs to transfer data.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

16.4 DSPI Shared IRQ Driver

16.4.1 Overview

This section describes the programming interface of the DSPI shared IRQ driver for master and slave Peripheral drivers.

Functions

- void [DSPI_DRV_EdmaIRQHandler](#) (uint32_t instance)
The function DSPI_DRV_EdmaIRQHandler passes IRQ control to either the master or slave driver.
- void [DSPI_DRV_IRQHandler](#) (uint32_t instance)
The function DSPI_DRV_IRQHandler passes IRQ control to either the master or slave driver.

Variables

- SPI_Type *const [g_dspiBase](#) [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type [g_dspiIrqId](#) [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.
- SPI_Type *const [g_dspiBase](#) [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type [g_dspiIrqId](#) [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.

16.4.2 Function Documentation

16.4.2.1 void DSPI_DRV_EdmaIRQHandler (uint32_t instance)

The address of the IRQ handlers are checked to make sure they are non-zero before they are called. If the IRQ handler's address is zero, it means that driver was not present in the link (because the IRQ handlers are marked as weak). This would actually be a program error, because it means the master/slave config for the IRQ was set incorrectly.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

16.4.2.2 void DSPI_DRV_IRQHandler (uint32_t instance)

The address of the IRQ handlers are checked to make sure they are non-zero before they are called. If the IRQ handler's address is zero, it means that driver was not present in the link (because the IRQ handlers are

DSPI Shared IRQ Driver

marked as weak). This would actually be a program error, because it means the master/slave configuration for the IRQ was set incorrectly.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

DSPI Slave Driver

16.5 DSPI Slave Driver

16.5.1 Overview

This chapter describes the programming interface of the DSPI slave mode peripheral driver. The DSPI slave peripheral driver supports using the SPI peripheral in slave mode. It supports transferring buffers of data with a single function call. When the DSPI is configured for slave mode operations, it must first be set up to perform a transfer and then wait for the master to initiate the transfer.

The driver is separated into two implementations: interrupt driven and DMA driven. The interrupt driven driver uses interrupts to alert the CPU that the DSPI module needs to service the SPI data transmit and receive operations. The enhanced DMA (eDMA) driven driver uses the eDMA module to transfer data between the buffers located in memory and the DSPI module transmit/receive buffers/FIFOs. In the subsequent chapters, the enhanced DMA-driven driver is referred to as the DMA-driven driver. The interrupt-driven and DMA-driven driver APIs are distinguished by the keyword "edma" in the source file name and by the keyword "Edma" in the API name. Each set of drivers have the same API functionality and are described in the following chapters. Note that the DMA-driven driver also uses interrupts to alert the CPU that the DMA has completed its transfer or that one final piece of data still needs to be received which is handled by the IRQ handler in the DMA driven driver. In both the interrupt and DMA drivers, the SPI module interrupts are enabled in the NVIC. In addition, the DMA driven-driver requests channels from the eDMA module. In the subsequent chapters, either set of drivers is referred to as the "DSPI slave driver" when discussing items that pertain to either driver. Note, when using the DMA driven DSPI driver, eDMA module needs to be initialized. An example is shown in the Initialization chapter.

This is a step-by-step overview to set up the DSPI for SPI slave mode operations. For API specific examples, see the examples below. This example uses the interrupt-driven APIs and a blocking transfer to illustrate a high-level step-by-step usage. The usage of eDMA driver is similar to interrupt-driven driver. Keep in mind that using interrupt and eDMA drivers in the same runtime application is not recommended because the SPI interrupt handler needs to be changed. The interrupt driver calls the [DSPI_DRV_IRQ_Handler\(\)](#) function and the eDMA driver calls the [DSPI_DRV_EdmaIRQHandler\(\)](#) function. See files `fsl_dspi_irq.c` and `fsl_dspi_edma_irq.c` for an example of these function calls.

```
// Initialize the DSPI
DSPI_DRV_SlaveInit(slaveInstance, &dspiSlaveState, &userConfig);
// Perform the transfer (however, waits for master to initiate the transfer)
DSPI_DRV_SlaveTransferBlocking(slaveInstance, s_dspiSourceBuffer,
    s_dspiSinkBuffer, 32, 1000);
// Do other transfers. When done with the DSPI, deinitialize to shut it down
DSPI_DRV_SlaveDeinit(slaveInstance);
```

Note that it is not normally recommended to mix interrupt and DMA-driven drivers in the same application. However, should the user decide to do so, separately set up and initialize another instance for DMA operations. The user can also de-initialize the current interrupt-driven DSPI instance and re-initialize it for DMA operations. Note, that, because the DMA-driven driver also uses interrupts, direct the IRQ handler from the vector table to the desired driver's IRQ handler. See files `fsl_dspi_irq.c` and `fsl_dspi_edma_irq.c` for examples to re-direct the IRQ handlers from the vector table to the interrupt-driven and DMA-driven driver IRQ handlers. These files need to be included in the applications project in order to direct the DSPI interrupt vectors to the proper IRQ handlers. The `fsl_dspi_shared_function.c` and `fsl_dspi_edma_shared_`

function.c files direct the interrupts from the vector table to the appropriate master or slave driver interrupt handler by checking the DSPI mode via the HAL function `DSPI_HAL_IsMaster(baseAddr)`.

When using the DSPI driver with the eDMA, some DSPI instances do not support separate DMA requests for transmit and receive channels. In those cases, with a single shared DMA request for transmit and receive DMA channels, the driver links one channel to the other in order to take advantage of DMA transfers. However, the drawback to using an instance with shared DMA requests limits the maximum amount of data the driver can transfer. This limit depends on the bits/frame setting.

For DSPI instances with separate transmit and receive DMA requests, the maximum number of bytes that can be transferred are: 8-bit setting: 32767 bytes 16-bit setting: 65534 bytes

For DSPI instances with a shared transmit and receive DMA request, the maximum number of bytes that can be transferred are: 8-bit setting: 511 bytes 16-bit setting: 1022 bytes

See the microcontroller-specific documentation to see which DSPI instance have separate or shared TX and RX DMA requests. Additionally, see the microcontroller-specific feature header file to see which DSPI instance have separate or shared transmit and receive DMA requests.

16.5.2 DSPI Runtime state of the DSPI slave driver

The DSPI slave driver uses a run-time state structure to track the ongoing data transfers. The state structure for the interrupt-driven driver is called the `dspi_slave_state_t`. The state structure for the DMA driven driver is called the `dspi_edma_slave_state_t`. The structure holds data that the DSPI slave peripheral driver uses to communicate between the transfer function and the interrupt handler and other driver functions. The interrupt handler also uses this information to keep track of its progress. The user is only responsible to pass the memory for this run-time state structure. The DSPI slave driver fills out the members.

16.5.3 DSPI User configuration structures

The DSPI slave driver uses instances of the user configuration structure for the DSPI slave driver. The user configuration structure for the interrupt driven driver is called the `dspi_slave_user_config_t`. The user configuration structure for the DMA driven driver is called the `dspi_edma_slave_user_config_t`. For this reason, the user can configure the most common settings of the DSPI peripheral with a single function call.

16.5.4 DSPI Setup and Initialization

To initialize the DSPI slave driver, first create and fill in a `dspi_slave_user_config_t` structure for the interrupt-driven driver or the `dspi_edma_slave_user_config_t` structure for the DMA-driven driver. This structure defines the data format settings for the SPI peripheral. The structure is not required after the driver is initialized and can be allocated on the stack. The user also must pass the memory for the run-time state structure.

This is an example code to initialize and configure the driver for interrupt and DMA operations:

DSPI Slave Driver

```

// Declare the module instance
uint32_t instance = 1;
uint32_t bitCount = 16;

// Interrupt-driven
dsppi_slave_state_t dsppiSlaveState;
// Update configurations
dsppi_slave_user_config_t slaveUserConfig;
slaveUserConfig.dataConfig.clkPhase =
    kDsppiClockPhase_FirstEdge;
slaveUserConfig.dataConfig.clkPolarity =
    kDsppiClockPolarity_ActiveHigh;
slaveUserConfig.dataConfig.bitsPerFrame = bitCount;
slaveUserConfig.dummyPattern = DSPI_DEFAULT_DUMMY_PATTERN;

// Initialize the slave (interrupt-driven)
DSPI_DRV_SlaveInit(instance, &dsppiSlaveState, &slaveUserConfig);

// DMA-driven
// First set up the eDMA peripheral
edma_state_t state; // <- The user allocates memory for this structure.
edma_user_config_t edmaUserConfig; // <- The user fills out members for this structure.
edmaUserConfig.chnArbitration = kEDMAChnArbitrationRoundRobin;
EDMA_DRV_Init(&state, &edmaUserConfig);

dsppi_edma_slave_state_t dsppiEdmaSlaveState;
// Update configurations
dsppi_edma_slave_user_config_t slaveEdmaUserConfig;
slaveEdmaUserConfig.dataConfig.clkPhase =
    kDsppiClockPhase_FirstEdge;
slaveEdmaUserConfig.dataConfig.clkPolarity =
    kDsppiClockPolarity_ActiveHigh;
slaveEdmaUserConfig.dataConfig.bitsPerFrame = bitCount;
slaveEdmaUserConfig.dummyPattern = DSPI_DEFAULT_DUMMY_PATTERN;

// Initialize the slave (DMA-driven)
DSPI_DRV_EdmaSlaveInit(instance, &dsppiEdmaSlaveState, &slaveEdmaUserConfig);

```

16.5.5 DSPI Blocking and non-blocking

The DSPI slave driver has two types of transfer functions, blocking and non-blocking call. With non-blocking calls, the user starts the transfer and then waits for event flags to set. `kDsppiTxDone` indicates the transmission is done and `kDsppiRxDone` indicates reception is done. With the blocking call, the function only returns after the related process is completed.

This is an example of blocking and non-blocking call (interrupt driven):

```

dsppi_status_t result;
// Blocking call example
result = DSPI_DRV_SlaveTransferBlocking(instance, // number of SPI peripheral
    sendBuffer, // pointer to transmit buffer, can be NULL
    receiveBuffer, // pointer to receive buffer, can be NULL
    transferSize, // size of receive and receive data
    10000); // Time out after 10000ms

// Check the result to find out whether the transfer was successful.

// Non-blocking call example
result = DSPI_DRV_SlaveTransfer(instance, // number of SPI peripheral
    sendBuffer, // pointer to transmit buffer, can be NULL
    receiveBuffer, // pointer to receive buffer, can be NULL
    transferSize); // size of receive and receive data

```

```
// Wait for transfer completion
while(kStatus_DSPI_Success != DSPI_DRV_SlaveGetTransferStatus(instance, NULL
));
// Must check the value of osaStatus to know if the transfer was successful.

// User has the option to terminate a transfer in progress
DSPI_DRV_SlaveAbortTransfer(instance);
```

Additionally, the DSPI supports eDMA transfers. To use the DSPI with DMA, see this example:

```
dspi_status_t result;
// Blocking call example
result = DSPI_DRV_EdmaSlaveTransferBlocking(instance, // number of SPI
    peripheral
        sendBuffer, // pointer to transmit buffer, can be NULL
        receiveBuffer, // pointer to receive buffer, can be NULL
        transferSize, // size of receive and receive data
        10000); // Time out after 10000ms
// Check the result to find out whether the transfer was successful.

// Non-blocking call example
result = DSPI_DRV_EdmaSlaveTransfer(instance, // number of SPI peripheral
    sendBuffer, // pointer to transmit buffer, can be NULL
    receiveBuffer, // pointer to receive buffer, can be NULL
    transferSize); // size of receive and receive data

// Wait for transfer completion
while(kStatus_DSPI_Success != DSPI_DRV_EdmaSlaveGetTransferStatus(
    instance, NULL));
// Check the value of osaStatus to find out whether the transfer was successful.

// User has the option to terminate a transfer in progress
DSPI_DRV_EdmaSlaveAbortTransfer(instance);
```

16.5.6 DSPI De-initialization

To de-initialize and shut down the DSPI module, call the function:

```
void DSPI_DRV_SlaveDeinit(instance);
```

If using eDMA-driven method, call the function

```
void DSPI_DRV_EdmaSlaveDeinit(instance);
```

Data Structures

- struct [dspi_dma_slave_user_config_t](#)
User configuration structure for the DSPI slave driver. [More...](#)
- struct [dspi_dma_slave_state_t](#)
Runtime state structure of the DSPI slave driver. [More...](#)
- struct [dspi_edma_slave_user_config_t](#)
User configuration structure for the DSPI slave driver. [More...](#)

DSPI Slave Driver

- struct `dspi_edma_slave_state_t`
Runtime state structure of the DSPI slave driver. [More...](#)
- struct `dspi_slave_user_config_t`
User configuration structure for the DSPI slave driver. [More...](#)
- struct `dspi_slave_state_t`
Runtime state of the DSPI slave driver. [More...](#)

Macros

- #define `DSPI_DMA_DEFAULT_DUMMY_PATTERN` (0u)
Dummy pattern, that DSPI slave will send when transmit data was not configured.
- #define `DSPI_EDMA_DEFAULT_DUMMY_PATTERN` (0u)
Dummy pattern, that DSPI slave will send when transmit data was not configured.
- #define `DSPI_DEFAULT_DUMMY_PATTERN` (0x0U)
Dummy pattern, that DSPI slave will send when transmit data was not configured.

Variables

- SPI_Type *const `g_dspiBase` [SPI_INSTANCE_COUNT]
Table of base pointers for SPI instances.
- const IRQn_Type `g_dspiIrqId` [SPI_INSTANCE_COUNT]
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.
- `dspi_data_format_config_t dspi_dma_slave_user_config_t::dataConfig`
Data format configuration structure.
- uint16_t `dspi_dma_slave_user_config_t::dummyPattern`
Dummy data value.
- uint32_t `dspi_dma_slave_state_t::bitsPerFrame`
Desired number of bits per frame.
- `dspi_status_t dspi_dma_slave_state_t::status`
Current state of slave.
- `event_t dspi_dma_slave_state_t::event`
Event to notify waiting task.
- uint16_t `dspi_dma_slave_state_t::errorCount`
Driver error count.
- uint32_t `dspi_dma_slave_state_t::dummyPattern`
Dummy data will be send when do not have data in transmit buffer.
- volatile bool `dspi_dma_slave_state_t::isTransferInProgress`
True if there is an active transfer.
- const uint8_t * `dspi_dma_slave_state_t::sendBuffer`
Pointer to transmit buffer.
- uint8_t * `dspi_dma_slave_state_t::receiveBuffer`
Pointer to receive buffer.
- volatile int32_t `dspi_dma_slave_state_t::remainingSendByteCount`
Number of bytes remaining to send.
- volatile int32_t `dspi_dma_slave_state_t::remainingReceiveByteCount`
Number of bytes remaining to receive.
- uint8_t `dspi_dma_slave_state_t::extraReceiveByte`
Number of extra receive bytes.
- bool `dspi_dma_slave_state_t::isSync`

- Indicates the function call is sync or async.*
- `dma_channel_t dspi_dma_slave_state_t::dmaTxChannel`
Structure definition for the DMA channel.
- `dma_channel_t dspi_dma_slave_state_t::dmaRxChannel`
Structure definition for the DMA channel.
- `SPI_Type *const g_dspiBase [SPI_INSTANCE_COUNT]`
Table of base pointers for SPI instances.
- `const IRQn_Type g_dspiIrqId [SPI_INSTANCE_COUNT]`
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.
- `dspi_data_format_config_t dspi_edma_slave_user_config_t::dataConfig`
Data format configuration structure.
- `uint16_t dspi_edma_slave_user_config_t::dummyPattern`
Dummy data value.
- `uint32_t dspi_edma_slave_state_t::bitsPerFrame`
Desired number of bits per frame.
- `dspi_status_t dspi_edma_slave_state_t::status`
Current state of slave.
- `event_t dspi_edma_slave_state_t::event`
Event to notify waiting task.
- `uint16_t dspi_edma_slave_state_t::errorCount`
Driver error count.
- `uint32_t dspi_edma_slave_state_t::dummyPattern`
Dummy data will be send when do not have data in transmit buffer.
- `volatile bool dspi_edma_slave_state_t::isTransferInProgress`
True if there is an active transfer.
- `const uint8_t * dspi_edma_slave_state_t::sendBuffer`
Pointer to transmit buffer.
- `uint8_t * dspi_edma_slave_state_t::receiveBuffer`
Pointer to receive buffer.
- `volatile int32_t dspi_edma_slave_state_t::remainingSendByteCount`
Number of bytes remaining to send.
- `volatile int32_t dspi_edma_slave_state_t::remainingReceiveByteCount`
Number of bytes remaining to receive.
- `uint8_t dspi_edma_slave_state_t::extraReceiveByte`
Number of extra receive bytes.
- `bool dspi_edma_slave_state_t::isSync`
Indicates the function call is sync or async.
- `edma_chn_state_t dspi_edma_slave_state_t::edmaTxChannel`
Structure definition for the eDMA channel.
- `edma_chn_state_t dspi_edma_slave_state_t::edmaRxChannel`
Structure definition for the eDMA channel.
- `SPI_Type *const g_dspiBase [SPI_INSTANCE_COUNT]`
Table of base pointers for SPI instances.
- `const IRQn_Type g_dspiIrqId [SPI_INSTANCE_COUNT]`
Table to save DSPI IRQ enumeration numbers defined in the CMSIS header file.

Initialization and shutdown

- `dspi_status_t DSPI_DRV_DmaSlaveInit` (uint32_t instance, `dspi_dma_slave_state_t *dspiState`, `const dspi_dma_slave_user_config_t *slaveConfig`)

DSPI Slave Driver

- Initializes a DSPI instance for a slave mode operation using the DMA mechanism.*
- [dspi_status_t DSPI_DRV_DmaSlaveDeinit](#) (uint32_t instance)
Shuts down a DSPI instance - DMA mechanism.

Blocking transfers

- [dspi_status_t DSPI_DRV_DmaSlaveTransferBlocking](#) (uint32_t instance, const uint8_t *sendBuffer, uint8_t *receiveBuffer, uint32_t transferByteCount, uint32_t timeOut)
Transfers data on the SPI bus using the DMA and blocking call.

Non-blocking transfers

- [dspi_status_t DSPI_DRV_DmaSlaveTransfer](#) (uint32_t instance, const uint8_t *sendBuffer, uint8_t *receiveBuffer, uint32_t transferByteCount)
Starts transferring data on the SPI bus using DMA.
- [dspi_status_t DSPI_DRV_DmaSlaveAbortTransfer](#) (uint32_t instance)
Aborts the transfer that started by a non-blocking call to the DMA transfer function.
- [dspi_status_t DSPI_DRV_DmaSlaveGetTransferStatus](#) (uint32_t instance, uint32_t *framesTransferred)
Returns whether the previous transfer is finished.

Initialization and shutdown

- [dspi_status_t DSPI_DRV_EdmaSlaveInit](#) (uint32_t instance, [dspi_edma_slave_state_t](#) *dspiState, const [dspi_edma_slave_user_config_t](#) *slaveConfig)
Initializes a DSPI instance for a slave mode operation, using eDMA mechanism.
- [dspi_status_t DSPI_DRV_EdmaSlaveDeinit](#) (uint32_t instance)
Shuts down a DSPI instance - eDMA mechanism.

Blocking transfers

- [dspi_status_t DSPI_DRV_EdmaSlaveTransferBlocking](#) (uint32_t instance, const uint8_t *sendBuffer, uint8_t *receiveBuffer, uint32_t transferByteCount, uint32_t timeOut)
Transfers data on the SPI bus using the eDMA and blocking call.

Non-blocking transfers

- [dspi_status_t DSPI_DRV_EdmaSlaveTransfer](#) (uint32_t instance, const uint8_t *sendBuffer, uint8_t *receiveBuffer, uint32_t transferByteCount)
Starts transfer data on SPI bus using eDMA.
- [dspi_status_t DSPI_DRV_EdmaSlaveAbortTransfer](#) (uint32_t instance)
Aborts the transfer that started by a non-blocking call to the eDMA transfer function.

- `dspi_status_t DSPI_DRV_EdmaSlaveGetTransferStatus` (`uint32_t instance`, `uint32_t *framesTransferred`)
Returns whether the previous transfer is finished.
- `void DSPI_DRV_EdmaSlaveIRQHandler` (`uint32_t instance`)
DSPI slave interrupt handler.

Initialization and shutdown

- `dspi_status_t DSPI_DRV_SlaveInit` (`uint32_t instance`, `dspi_slave_state_t *dspiState`, `const dspi_slave_user_config_t *slaveConfig`)
Initializes a DSPI instance for a slave mode operation, using interrupt mechanism.
- `dspi_status_t DSPI_DRV_SlaveDeinit` (`uint32_t instance`)
Shuts down a DSPI instance - interrupt mechanism.

Blocking transfers

- `dspi_status_t DSPI_DRV_SlaveTransferBlocking` (`uint32_t instance`, `const uint8_t *sendBuffer`, `uint8_t *receiveBuffer`, `uint32_t transferByteCount`, `uint32_t timeout`)
Transfers data on SPI bus using interrupt and blocking call.

Non-blocking transfers

- `dspi_status_t DSPI_DRV_SlaveTransfer` (`uint32_t instance`, `const uint8_t *sendBuffer`, `uint8_t *receiveBuffer`, `uint32_t transferByteCount`)
Starts transfer data on SPI bus using interrupt and a non-blocking call.
- `dspi_status_t DSPI_DRV_SlaveAbortTransfer` (`uint32_t instance`)
Aborts the transfer that started by a non-blocking call to a transfer function.
- `dspi_status_t DSPI_DRV_SlaveGetTransferStatus` (`uint32_t instance`, `uint32_t *framesTransferred`)
Returns whether the previous transfer is finished.
- `void DSPI_DRV_SlaveIRQHandler` (`uint32_t instance`)
DSPI Slave Generic IRQ handler.

16.5.7 Data Structure Documentation

16.5.7.1 struct `dspi_dma_slave_user_config_t`

Data Fields

- `dspi_data_format_config_t dataConfig`
Data format configuration structure.
- `uint16_t dummyPattern`
Dummy data value.

DSPI Slave Driver

16.5.7.2 struct dsp_i_dma_slave_state_t

This structure holds data that is used by the DSPI slave peripheral driver to communicate between the transfer function and the interrupt handler. The user needs to pass in the memory for this structure and the driver fills out the members.

Data Fields

- `uint32_t bitsPerFrame`
Desired number of bits per frame.
- `dspi_status_t status`
Current state of slave.
- `event_t event`
Event to notify waiting task.
- `uint16_t errorCount`
Driver error count.
- `uint32_t dummyPattern`
Dummy data will be send when do not have data in transmit buffer.
- `volatile bool isTransferInProgress`
True if there is an active transfer.
- `const uint8_t * sendBuffer`
Pointer to transmit buffer.
- `uint8_t * receiveBuffer`
Pointer to receive buffer.
- `volatile int32_t remainingSendByteCount`
Number of bytes remaining to send.
- `volatile int32_t remainingReceiveByteCount`
Number of bytes remaining to receive.
- `uint8_t extraReceiveByte`
Number of extra receive bytes.
- `bool isSync`
Indicates the function call is sync or async.
- `dma_channel_t dmaTxChannel`
Structure definition for the DMA channel.
- `dma_channel_t dmaRxChannel`
Structure definition for the DMA channel.

16.5.7.3 struct dsp_i_edma_slave_user_config_t

Data Fields

- `dspi_data_format_config_t dataConfig`
Data format configuration structure.
- `uint16_t dummyPattern`
Dummy data value.

16.5.7.4 struct dsp_i_edma_slave_state_t

This structure holds data that is used by the DSPI slave peripheral driver to communicate between the transfer function and the interrupt handler. The user needs to pass in the memory for this structure and the driver fills out the members.

Data Fields

- `uint32_t bitsPerFrame`
Desired number of bits per frame.
- `dspi_status_t status`
Current state of slave.
- `event_t event`
Event to notify waiting task.
- `uint16_t errorCount`
Driver error count.
- `uint32_t dummyPattern`
Dummy data will be send when do not have data in transmit buffer.
- `volatile bool isTransferInProgress`
True if there is an active transfer.
- `const uint8_t * sendBuffer`
Pointer to transmit buffer.
- `uint8_t * receiveBuffer`
Pointer to receive buffer.
- `volatile int32_t remainingSendByteCount`
Number of bytes remaining to send.
- `volatile int32_t remainingReceiveByteCount`
Number of bytes remaining to receive.
- `uint8_t extraReceiveByte`
Number of extra receive bytes.
- `bool isSync`
Indicates the function call is sync or async.
- `edma_chn_state_t edmaTxChannel`
Structure definition for the eDMA channel.
- `edma_chn_state_t edmaRxChannel`
Structure definition for the eDMA channel.

16.5.7.5 struct dsp_i_slave_user_config_t

Data Fields

- `dspi_data_format_config_t dataConfig`
Data format configuration structure.
- `uint16_t dummyPattern`
Dummy data value.

DSPI Slave Driver

16.5.7.6 struct dspi_slave_state_t

This structure holds data that is used by the DSPI slave peripheral driver to communicate between the transfer function and the interrupt handler. The user needs to pass in the memory for this structure and the driver fills out the members.

Data Fields

- uint32_t **bitsPerFrame**
Desired number of bits per frame.
- dspi_status_t **status**
Current state of slave.
- event_t **event**
Event to notify waiting task.
- uint16_t **errorCount**
Driver error count.
- uint32_t **dummyPattern**
Dummy data will be send when do not have data in transmit buffer.
- volatile bool **isTransferInProgress**
True if there is an active transfer.
- const uint8_t * **sendBuffer**
Pointer to transmit buffer.
- uint8_t * **receiveBuffer**
Pointer to receive buffer.
- volatile int32_t **remainingSendByteCount**
Number of bytes remaining to send.
- volatile int32_t **remainingReceiveByteCount**
Number of bytes remaining to receive.
- bool **isSync**
Indicates the function call is sync or async.

16.5.7.6.0.89 Field Documentation

16.5.7.6.0.89.1 volatile bool dspi_slave_state_t::isTransferInProgress

16.5.7.6.0.89.2 volatile int32_t dspi_slave_state_t::remainingSendByteCount

16.5.7.6.0.89.3 volatile int32_t dspi_slave_state_t::remainingReceiveByteCount

16.5.8 Function Documentation

16.5.8.1 dspi_status_t DSPI_DRV_DmaSlaveInit (uint32_t *instance*, dspi_dma_slave_state_t * *dspiState*, const dspi_dma_slave_user_config_t * *slaveConfig*)

This function ungates the clock to the DSPI module, initializes the DSPI for slave mode, and initializes DMA channels. After it is initialized, the DSPI module is configured in slave mode and the user can start transmitting and receiving data by calling send, receive, and transfer functions. This function indicates

that the DSPI slave uses the DMA mechanism.

DSPI Slave Driver

Parameters

| | |
|--------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiState</i> | The pointer to the DSPI slave driver state structure. |
| <i>slaveConfig</i> | The configuration structure dspi_dma_slave_user_config_t which configures the data bus format. |

Returns

An error code or `kStatus_DSPI_Success`.

16.5.8.2 `dspi_status_t DSPI_DRV_DmaSlaveDeinit (uint32_t instance)`

Disables the DSPI module, gates its clock, changes the DSPI slave driver state to NonInit for DSPI slave module, which is initialized with the DMA mechanism. After de-initialization, the user can re-initialize the DSPI slave module with other methods.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization or error code

16.5.8.3 `dspi_status_t DSPI_DRV_DmaSlaveTransferBlocking (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount, uint32_t timeOut)`

This function checks driver status and mechanism and transmits/receives data through the SPI bus. If the `sendBuffer` is NULL, transmit process is ignored. If the `receiveBuffer` is NULL, the receive process is ignored. If both the `receiveBuffer` and the `sendBuffer` are available, the progress of both the transmit and receive is processed. If only the `receiveBuffer` is available, the receive is processed, Otherwise, the transmit is processed. This function only returns when its processes are complete. This function uses the DMA mechanism.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of DSPI peripheral |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |
| <i>timeOut</i> | The maximum number of milliseconds that function waits before the timed out is reached. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available. kStatus_DSPI_Timeout if time out reached while transferring is in progress.

16.5.8.4 `dspi_status_t DSPI_DRV_DmaSlaveTransfer (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount)`

This function checks the driver status and sets buffer pointers to receive and transmit SPI data. If the sendBuffer is NULL, the transmit process is ignored. If the receiveBuffer is NULL, the receive process is ignored. If both the receiveBuffer and sendBuffer are available, the transfer is done when the kDspi-TxDone and the kDspiRxDone flags are set. If only the receiveBuffer is available, the transfer is done when the kDspiRxDone flag is set. Otherwise, the transfer is done when the kDspiTxDone flag is set. This function uses the DMA mechanism.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of DSPI peripheral. |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available.

16.5.8.5 `dspi_status_t DSPI_DRV_DmaSlaveAbortTransfer (uint32_t instance)`

This function stops the transfer which was started by the [DSPI_DRV_DmaSlaveTransfer\(\)](#) function.

DSPI Slave Driver

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The instance number of DSPI peripheral |
|-----------------|--|

Returns

kStatus_DSPI_Success if everything is OK. kStatus_DSPI_InvalidMechanism if the current transaction does not use DMA mechanism.

16.5.8.6 `dspi_status_t DSPI_DRV_DmaSlaveGetTransferStatus (uint32_t instance, uint32_t * framesTransferred)`

When performing an a-sync transfer, call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to that point.

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value that is filled in with the number of frames that have been sent in the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. framesTransferred is filled with the number of words that have been transferred so far.

16.5.8.7 `dspi_status_t DSPI_DRV_EdmaSlaveInit (uint32_t instance, dspi_edma_slave_state_t * dspiState, const dspi_edma_slave_user_config_t * slaveConfig)`

This function un-gates the clock to the DSPI module, initializes the DSPI for slave mode and initializes eDMA channels. After it is initialized, the DSPI module is configured in slave mode and user can start transmit, receive data by calls send, receive, transfer functions. This function indicates DSPI slave uses the eDMA mechanism.

Parameters

| | |
|--------------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiState</i> | The pointer to the DSPI slave driver state structure. |
| <i>slaveConfig</i> | The configuration structure dspi_edma_slave_user_config_t which configures the data bus format. |

Returns

An error code or `kStatus_DSPI_Success`.

16.5.8.8 dspi_status_t DSPI_DRV_EdmaSlaveDeinit (uint32_t instance)

Disables the DSPI module, gates its clock, changes the DSPI slave driver state to NonInit for DSPI slave module which is initialized with the eDMA mechanism. After de-initialization, the user can re-initialize the DSPI slave module with other mechanisms.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization or error code

16.5.8.9 dspi_status_t DSPI_DRV_EdmaSlaveTransferBlocking (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount, uint32_t timeOut)

This function checks driver status, mechanism and transmits/receives data through SPI bus. If `sendBuffer` is NULL, transmit process is ignored, and if the `receiveBuffer` is NULL, the receive process is ignored. If both the `receiveBuffer` and the `sendBuffer` are available, the transmit and receive progress is processed. If only the `receiveBuffer` is available, the receive is processed, Otherwise, the transmit is processed. This function only returns when its processes are complete. This function uses the eDMA mechanism.

Parameters

DSPI Slave Driver

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of DSPI peripheral |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |
| <i>timeOut</i> | The maximum number of milliseconds that function will wait before timed out reached. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available. kStatus_DSPI_Timeout if time out reached while transferring is in progress.

16.5.8.10 `dspi_status_t DSPI_DRV_EdmaSlaveTransfer (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount)`

This function checks the driver status then sets buffer pointers to receive and transmit SPI data. If the sendBuffer is NULL, transmit process is ignored. If the receiveBuffer is NULL, the receive process is ignored. If both the receiveBuffer and sendBuffer are available, the transfer is done when the kDspiTxDone and the kDspiRxDone are set. If only the receiveBuffer is available, the transfer is done when the kDspiRxDone flag is set. Otherwise, the transfer is done when the kDspiTxDone is set. This function uses the eDMA mechanism.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of DSPI peripheral. |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available.

16.5.8.11 `dspi_status_t DSPI_DRV_EdmaSlaveAbortTransfer (uint32_t instance)`

This function stops the transfer which was started by the [DSPI_DRV_EdmaSlaveTransfer\(\)](#) function.

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The instance number of DSPI peripheral |
|-----------------|--|

Returns

kStatus_DSPI_Success if everything is ok. kStatus_DSPI_InvalidMechanism if the current transaction does not use eDMA mechanism.

16.5.8.12 dspi_status_t DSPI_DRV_EdmaSlaveGetTransferStatus (uint32_t *instance*, uint32_t * *framesTransferred*)

When performing an a-sync transfer, the user can call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to now.

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value that is filled in with the number of frames that have been sent in the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. framesTransferred is filled with the number of words that have been transferred so far.

16.5.8.13 void DSPI_DRV_EdmaSlaveIRQHandler (uint32_t *instance*)

This function is DSPI slave interrupt handler using eDMA mechanism. The purpose of this interrupt handler is indicates when the transfer is really finished. The eDMA only used to copy data from/to RX FIFO/TX FIFO, but it not sure the data was transmitted to the master. So must have to enable this interrupt to do it. This interrupt only be enabled when the last four FIFO will be transmitted.

Parameters

DSPI Slave Driver

| | |
|-----------------|----------------|
| <i>instance</i> | The SPI number |
|-----------------|----------------|

16.5.8.14 `dspi_status_t DSPI_DRV_SlaveInit (uint32_t instance, dspi_slave_state_t * dspiState, const dspi_slave_user_config_t * slaveConfig)`

This function un-gates the clock to the DSPI module, initializes the DSPI for slave mode. Once initialized, the DSPI module is configured in slave mode and user can start transmit, receive data by calls send, receive, transfer functions. This function indicates DSPI slave will use interrupt mechanism.

Parameters

| | |
|--------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>dspiState</i> | The pointer to the DSPI slave driver state structure. |
| <i>slaveConfig</i> | The configuration structure dspi_slave_user_config_t which configures the data bus format. |

Returns

An error code or `kStatus_DSPI_Success`.

16.5.8.15 `dspi_status_t DSPI_DRV_SlaveDeinit (uint32_t instance)`

Disables the DSPI module, gates its clock, change DSPI slave driver state to NonInit for DSPI slave module which is initialized with interrupt mechanism. After de-initialized, user can re-initialize DSPI slave module with other mechanisms.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

Returns

`kStatus_DSPI_Success` indicating successful de-initialization or error code

16.5.8.16 `dspi_status_t DSPI_DRV_SlaveTransferBlocking (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount, uint32_t timeout)`

This function check driver status, mechanism and transmit/receive data through SPI bus. If `sendBuffer` is NULL, the transmit process is ignored, and if `receiveBuffer` is NULL the receive process is ignored. If

both receiveBuffer and sendBuffer are available, both the transmit and the receive progress are processed. If only the receiveBuffer is available, the receive is processed. Otherwise, the transmit is processed. This function only returns when its processes are complete. This function uses an interrupt mechanism.

DSPI Slave Driver

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of DSPI peripheral |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |
| <i>timeout</i> | The maximum number of milliseconds that function will wait before timed out reached. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available. kStatus_DSPI_Timeout if time out reached while transferring is in progress.

16.5.8.17 `dspi_status_t DSPI_DRV_SlaveTransfer (uint32_t instance, const uint8_t * sendBuffer, uint8_t * receiveBuffer, uint32_t transferByteCount)`

This function checks the driver status and sets buffer pointers to receive and transmit the SPI data. If the sendBuffer is NULL, the transmit process is ignored. If the receiveBuffer is NULL, the receive process is ignored. If both the receiveBuffer and the sendBuffer are , available the transfer is done when the kDspi-TxDone and the kDspiRxDone are set. If only the receiveBuffer is available, the transfer is done when the kDspiRxDone flag is set. Otherwise, the transfer is done when the kDspiTxDone is set. This function uses an interrupt mechanism.

Parameters

| | |
|---------------------------|---|
| <i>instance</i> | The instance number of DSPI peripheral |
| <i>sendBuffer</i> | The pointer to data that user wants to transmit. |
| <i>receiveBuffer</i> | The pointer to data that user wants to store received data. |
| <i>transferByte-Count</i> | The number of bytes to send and receive. |

Returns

kStatus_DSPI_Success if driver starts to send/receive data successfully. kStatus_DSPI_Error if driver is error and needs to clean error. kStatus_DSPI_Busy if driver is receiving/transmitting data and not available.

16.5.8.18 `dspi_status_t DSPI_DRV_SlaveAbortTransfer (uint32_t instance)`

This function stops the transfer which started by calling the [DSPI_DRV_SlaveTransfer\(\)](#) function.

DSPI Slave Driver

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The instance number of DSPI peripheral |
|-----------------|--|

Returns

kStatus_DSPI_Success if everything is OK. kStatus_DSPI_InvalidMechanism if the current transaction does not use interrupt mechanism.

16.5.8.19 dspi_status_t DSPI_DRV_SlaveGetTransferStatus (uint32_t *instance*, uint32_t * *framesTransferred*)

When performing an a-sync transfer, the user can call this function to ascertain the state of the current transfer: in progress (or busy) or complete (success). In addition, if the transfer is still in progress, the user can get the number of words that have been transferred up to now.

Parameters

| | |
|---------------------------|--|
| <i>instance</i> | The instance number of the DSPI peripheral. |
| <i>frames-Transferred</i> | Pointer to value that is filled in with the number of frames that have been sent in the active transfer. A frame is defined as the number of bits per frame. |

Returns

kStatus_DSPI_Success The transfer has completed successfully, or kStatus_DSPI_Busy The transfer is still in progress. *framesTransferred* is filled with the number of words that have been transferred so far.

16.5.8.20 void DSPI_DRV_SlaveIRQHandler (uint32_t *instance*)

This handler check errors of driver and it puts data into Tx FIFO, gets data from Rx FIFO whenever data transmitting/received.

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The instance number of the DSPI peripheral. |
|-----------------|---|

16.5.9 Variable Documentation

16.5.9.1 SPI_Type* const g_dspiBase[SPI_INSTANCE_COUNT]

Chapter 17

Enhanced Direct Memory Access (eDMA)

17.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Direct Memory Access (eDMA) block of Kinetis devices.

Modules

- [eDMA HAL driver](#)
- [eDMA Peripheral driver](#)
- [eDMA request](#)

eDMA HAL driver

17.2 eDMA HAL driver

17.2.1 Overview

This section describes the programming interface of the eDMA HAL driver.

Data Structures

- struct `edma_transfer_config_t`
eDMA transfer size configuration. [More...](#)
- struct `edma_miniorloop_offset_config_t`
eDMA TCD minor loop mapping configuration [More...](#)
- struct `edma_error_status_all_t`
Error status of the eDMA module. [More...](#)
- struct `edma_software_tcd_t`
eDMA TCD [More...](#)

Enumerations

- enum `edma_status_t` { ,
`kStatus_EDMA_InvalidArgument` = 1U,
`kStatus_EDMA_Fail` = 2U }
Error code for the eDMA Driver.
- enum `edma_channel_arbitration_t` {
`kEDMAChnArbitrationFixedPriority` = 0U,
`kEDMAChnArbitrationRoundrobin` }
eDMA channel arbitration algorithm used to select among channels.
- enum `edma_channel_priority_t`
eDMA channel priority setting
- enum `edma_modulo_t`
eDMA modulo configuration
- enum `edma_transfer_size_t`
eDMA transfer configuration
- enum `edma_channel_indicator_t` { `kEDMAChannel0` = 0U }
eDMA channel configuration.
- enum `edma_bandwidth_config_t` {
`kEDMABandwidthStallNone` = 0U,
`kEDMABandwidthStall4Cycle` = 2U,
`kEDMABandwidthStall8Cycle` = 3U }
Bandwidth control configuration.

eDMA HAL driver module level operation

- void `EDMA_HAL_Init` (DMA_Type *base)
Initializes the eDMA module to a known state.
- void `EDMA_HAL_CancelTransfer` (DMA_Type *base)

- *Cancels the remaining data transfer.*
- void [EDMA_HAL_ErrorCancelTransfer](#) (DMA_Type *base)
- *Cancels the remaining data transfer and treats it as an error condition.*
- static void [EDMA_HAL_SetHaltCmd](#) (DMA_Type *base, bool halt)
- *Halts/resumes the DMA Operations.*
- static void [EDMA_HAL_SetHaltOnErrorCmd](#) (DMA_Type *base, bool haltOnError)
- *Halts or does not halt the eDMA module when an error occurs.*
- static void [EDMA_HAL_SetDebugCmd](#) (DMA_Type *base, bool enable)
- *Enables/Disables the eDMA debug mode.*

eDMA HAL driver channel priority and arbitration configuration.

- static void [EDMA_HAL_SetChannelPreemptMode](#) (DMA_Type *base, uint32_t channel, bool preempt, bool preemption)
- *Sets the preempt and preemption feature for the eDMA channel.*
- static void [EDMA_HAL_SetChannelPriority](#) (DMA_Type *base, uint32_t channel, [edma_channel_priority_t](#) priority)
- *Sets the eDMA channel priority.*
- static void [EDMA_HAL_SetChannelArbitrationMode](#) (DMA_Type *base, [edma_channel_arbitration_t](#) channelArbitration)
- *Sets the channel arbitration algorithm.*

eDMA HAL driver configuration and operation.

- static void [EDMA_HAL_SetMinorLoopMappingCmd](#) (DMA_Type *base, bool enable)
- *Enables/Disables the minor loop mapping.*
- static void [EDMA_HAL_SetContinuousLinkCmd](#) (DMA_Type *base, bool continuous)
- *Enables or disables the continuous transfer mode.*
- [edma_error_status_all_t](#) [EDMA_HAL_GetErrorStatus](#) (DMA_Type *base)
- *Gets the error status of the eDMA module.*
- void [EDMA_HAL_SetErrorIntCmd](#) (DMA_Type *base, bool enable, [edma_channel_indicator_t](#) channel)
- *Enables/Disables the error interrupt for channels.*
- static uint32_t [EDMA_HAL_GetErrorIntStatusFlag](#) (DMA_Type *base)
- *Gets the eDMA error interrupt status.*
- static void [EDMA_HAL_ClearErrorIntStatusFlag](#) (DMA_Type *base, [edma_channel_indicator_t](#) channel)
- *Clears the error interrupt status for the eDMA channel or channels.*
- void [EDMA_HAL_SetDmaRequestCmd](#) (DMA_Type *base, [edma_channel_indicator_t](#) channel, bool enable)
- *Enables/disables the DMA request for the channel or all channels.*
- static bool [EDMA_HAL_GetDmaRequestStatusFlag](#) (DMA_Type *base, uint32_t channel)
- *Gets the eDMA channel DMA request status.*
- static void [EDMA_HAL_ClearDoneStatusFlag](#) (DMA_Type *base, [edma_channel_indicator_t](#) channel)
- *Clears the done status for a channel or all channels.*

eDMA HAL driver

- static void [EDMA_HAL_TriggerChannelStart](#) (DMA_Type *base, [edma_channel_indicator_t](#) channel)
Triggers the eDMA channel.
- static bool [EDMA_HAL_GetIntStatusFlag](#) (DMA_Type *base, uint32_t channel)
Gets the eDMA channel interrupt request status.
- static void [EDMA_HAL_ClearIntStatusFlag](#) (DMA_Type *base, [edma_channel_indicator_t](#) channel)
Clears the interrupt status for the eDMA channel or all channels.

eDMA HAL driver hardware TCD configuration functions.

- void [EDMA_HAL_HTCDClearReg](#) (DMA_Type *base, uint32_t channel)
Clears all registers to 0 for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcAddr](#) (DMA_Type *base, uint32_t channel, uint32_t address)
Configures the source address for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcOffset](#) (DMA_Type *base, uint32_t channel, int16_t offset)
Configures the source address signed offset for the hardware TCD.
- void [EDMA_HAL_HTCDSrcAttribute](#) (DMA_Type *base, uint32_t channel, [edma_modulo_t](#) srcModulo, [edma_modulo_t](#) destModulo, [edma_transfer_size_t](#) srcTransferSize, [edma_transfer_size_t](#) destTransferSize)
Configures the transfer attribute for the eDMA channel.
- void [EDMA_HAL_HTCDSrcNbytes](#) (DMA_Type *base, uint32_t channel, uint32_t nbytes)
Configures the nbytes for the eDMA channel.
- uint32_t [EDMA_HAL_HTCDSrcNbytes](#) (DMA_Type *base, uint32_t channel)
Gets the nbytes configuration data for the hardware TCD.
- void [EDMA_HAL_HTCDSrcMinorLoopOffset](#) (DMA_Type *base, uint32_t channel, [edma_miniorloop_offset_config_t](#) *config)
Configures the minor loop offset for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcLastAdjust](#) (DMA_Type *base, uint32_t channel, int32_t size)
Configures the last source address adjustment for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcDestAddr](#) (DMA_Type *base, uint32_t channel, uint32_t address)
Configures the destination address for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcDestOffset](#) (DMA_Type *base, uint32_t channel, int16_t offset)
Configures the destination address signed offset for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcDestLastAdjust](#) (DMA_Type *base, uint32_t channel, uint32_t adjust)
Configures the last source address adjustment.
- void [EDMA_HAL_HTCDSrcScatterGatherLink](#) (DMA_Type *base, uint32_t channel, [edma_software_tcd_t](#) *stcd)
Configures the memory address for the next transfer TCD for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcBandwidth](#) (DMA_Type *base, uint32_t channel, [edma_bandwidth_config_t](#) bandwidth)
Configures the bandwidth for the hardware TCD.
- static void [EDMA_HAL_HTCDSrcChannelMajorLink](#) (DMA_Type *base, uint32_t channel, uint32_t majorChannel, bool enable)

- Configures the major channel link the hardware TCD.*

 - static void [EDMA_HAL_HTCDSetScatterGatherCmd](#) (DMA_Type *base, uint32_t channel, bool enable)

Enables/disables the scatter/gather feature for the hardware TCD.

 - static void [EDMA_HAL_HTCDSetDisableDmaRequestAfterTCDDoneCmd](#) (DMA_Type *base, uint32_t channel, bool disable)

Disables/enables the DMA request after the major loop completes for the hardware TCD.

 - static void [EDMA_HAL_HTCDSetHalfCompleteIntCmd](#) (DMA_Type *base, uint32_t channel, bool enable)

Enables/disables the half complete interrupt for the hardware TCD.

 - static void [EDMA_HAL_HTCDSetIntCmd](#) (DMA_Type *base, uint32_t channel, bool enable)

Enables/disables the interrupt after the major loop completes for the hardware TCD.

 - static void [EDMA_HAL_HTCDTriggerChannelStart](#) (DMA_Type *base, uint32_t channel)

Triggers the start bits for the hardware TCD.

 - static bool [EDMA_HAL_HTCDGetChannelActiveStatus](#) (DMA_Type *base, uint32_t channel)

Checks whether the channel is running for the hardware TCD.

 - void [EDMA_HAL_HTCDSetChannelMinorLink](#) (DMA_Type *base, uint32_t channel, uint32_t linkChannel, bool enable)

Sets the channel minor link for the hardware TCD.

 - void [EDMA_HAL_HTCDSetMajorCount](#) (DMA_Type *base, uint32_t channel, uint32_t count)

Sets the major iteration count according to minor loop channel link setting.

 - uint32_t [EDMA_HAL_HTCDGetFinishedBytes](#) (DMA_Type *base, uint32_t channel)

Gets the number of bytes already transferred for the hardware TCD.

 - uint32_t [EDMA_HAL_HTCDGetUnfinishedBytes](#) (DMA_Type *base, uint32_t channel)

Gets the number of bytes haven't transferred for the hardware TCD.

 - static bool [EDMA_HAL_HTCDGetDoneStatusFlag](#) (DMA_Type *base, uint32_t channel)

Gets the channel done status.

 - uint32_t [EDMA_HAL_HTCDGetBeginMajorCount](#) (DMA_Type *base, uint32_t channel)

Gets the channel Begin major count.

 - uint32_t [EDMA_HAL_HTCDGetCurrentMajorCount](#) (DMA_Type *base, uint32_t channel)

Gets the channel current major count.

eDMA HAL driver software TCD configuration functions.

- static void [EDMA_HAL_STCDSetSrcAddr](#) (edma_software_tcd_t *stcd, uint32_t address)
- Configures the source address for the software TCD.*
- static void [EDMA_HAL_STCDSetSrcOffset](#) (edma_software_tcd_t *stcd, int16_t offset)
- Configures the source address signed offset for the software TCD.*
- void [EDMA_HAL_STCDSetAttribute](#) (edma_software_tcd_t *stcd, edma_modulo_t srcModulo, edma_modulo_t destModulo, edma_transfer_size_t srcTransferSize, edma_transfer_size_t destTransferSize)
- Configures the transfer attribute for software TCD.*
- void [EDMA_HAL_STCDSetNbytes](#) (DMA_Type *base, edma_software_tcd_t *stcd, uint32_t nbytes)
- Configures the nbytes for software TCD.*
- void [EDMA_HAL_STCDSetMinorLoopOffset](#) (DMA_Type *base, edma_software_tcd_t *stcd, edma_miniorloop_offset_config_t *config)
- Configures the minor loop offset for the software TCD.*
- static void [EDMA_HAL_STCDSetSrcLastAdjust](#) (edma_software_tcd_t *stcd, int32_t size)

eDMA HAL driver

- Configures the last source address adjustment for the software TCD.*

 - static void [EDMA_HAL_STCDSetDestAddr](#) ([edma_software_tcd_t](#) *stcd, [uint32_t](#) address)

Configures the destination address for the software TCD.

 - static void [EDMA_HAL_STCDSetDestOffset](#) ([edma_software_tcd_t](#) *stcd, [int16_t](#) offset)

Configures the destination address signed offset for the software TCD.

 - static void [EDMA_HAL_STCDSetDestLastAdjust](#) ([edma_software_tcd_t](#) *stcd, [uint32_t](#) adjust)

Configures the last source address adjustment.

 - void [EDMA_HAL_STCDSetScatterGatherLink](#) ([edma_software_tcd_t](#) *stcd, [edma_software_tcd_t](#) *nextStcd)

Configures the memory address for the next transfer TCD for the software TCD.

 - static void [EDMA_HAL_STCDSetBandwidth](#) ([edma_software_tcd_t](#) *stcd, [edma_bandwidth_config_t](#) bandwidth)

Configures the bandwidth for the software TCD.

 - static void [EDMA_HAL_STCDSetChannelMajorLink](#) ([edma_software_tcd_t](#) *stcd, [uint32_t](#) majorChannel, [bool](#) enable)

Configures the major channel link the software TCD.

 - static void [EDMA_HAL_STCDSetScatterGatherCmd](#) ([edma_software_tcd_t](#) *stcd, [bool](#) enable)

Enables/disables the scatter/gather feature for the software TCD.

 - static void [EDMA_HAL_STCDSetDisableDmaRequestAfterTCDDoneCmd](#) ([edma_software_tcd_t](#) *stcd, [bool](#) disable)

Disables/enables the DMA request after the major loop completes for the software TCD.

 - static void [EDMA_HAL_STCDSetHalfCompleteIntCmd](#) ([edma_software_tcd_t](#) *stcd, [bool](#) enable)

Enables/disables the half complete interrupt for the software TCD.

 - static void [EDMA_HAL_STCDSetIntCmd](#) ([edma_software_tcd_t](#) *stcd, [bool](#) enable)

Enables/disables the interrupt after the major loop completes for the software TCD.

 - static void [EDMA_HAL_STCDTriggerChannelStart](#) ([edma_software_tcd_t](#) *stcd)

Triggers the start bits for the software TCD.

 - void [EDMA_HAL_STCDSetChannelMinorLink](#) ([edma_software_tcd_t](#) *stcd, [uint32_t](#) linkChannel, [bool](#) enable)

Sets the channel minor link for the software TCD.

 - void [EDMA_HAL_STCDSetMajorCount](#) ([edma_software_tcd_t](#) *stcd, [uint32_t](#) count)

Sets the major iteration count according to the minor loop channel link setting.

 - void [EDMA_HAL_PushSTCDToHTCD](#) ([DMA_Type](#) *base, [uint32_t](#) channel, [edma_software_tcd_t](#) *stcd)

Copies the software TCD configuration to the hardware TCD.

 - [edma_status_t](#) [EDMA_HAL_STCDSetBasicTransfer](#) ([DMA_Type](#) *base, [edma_software_tcd_t](#) *stcd, [edma_transfer_config_t](#) *config, [bool](#) enableInt, [bool](#) disableDmaRequest)

Sets the basic transfer for the software TCD.

17.2.2 Data Structure Documentation

17.2.2.1 struct edma_transfer_config_t

This structure configures the basic source/destination transfer attribute. This figure shows the eDMA's transfer model:

| Transfer Size | |

```

Minor Loop |_____| Major loop Count 1 |
Count | Transfer Size ||
_____||_____||_____||-> Minor loop complete
_____
|||
|_____| Major Loop Count 2 |
|||
|_____||_____||-> Minor loop Complete
-----> Major loop complete

```

Data Fields

- `uint32_t srcAddr`
Memory address pointing to the source data.
- `uint32_t destAddr`
Memory address pointing to the destination data.
- `edma_transfer_size_t srcTransferSize`
Source data transfer size.
- `edma_transfer_size_t destTransferSize`
Destination data transfer size.
- `int16_t srcOffset`
Sign-extended offset applied to the current source address to form the next-state value as each source read/write is completed.
- `uint32_t srcLastAddrAdjust`
Last source address adjustment.
- `uint32_t destLastAddrAdjust`
Last destination address adjustment.
- `edma_modulo_t srcModulo`
Source address modulo.
- `edma_modulo_t destModulo`
Destination address modulo.
- `uint32_t minorLoopCount`
Minor bytes transfer count.
- `uint16_t majorLoopCount`
Major iteration count.

eDMA HAL driver

17.2.2.1.0.90 Field Documentation

17.2.2.1.0.90.1 `uint32_t edma_transfer_config_t::srcAddr`

17.2.2.1.0.90.2 `uint32_t edma_transfer_config_t::destAddr`

17.2.2.1.0.90.3 `edma_transfer_size_t edma_transfer_config_t::srcTransferSize`

17.2.2.1.0.90.4 `edma_transfer_size_t edma_transfer_config_t::destTransferSize`

17.2.2.1.0.90.5 `int16_t edma_transfer_config_t::srcOffset`

17.2.2.1.0.90.6 `uint32_t edma_transfer_config_t::srcLastAddrAdjust`

17.2.2.1.0.90.7 `uint32_t edma_transfer_config_t::destLastAddrAdjust`

Note here it is only valid when scatter/gather feature is not enabled.

17.2.2.1.0.90.8 `edma_modulo_t edma_transfer_config_t::srcModulo`

17.2.2.1.0.90.9 `edma_modulo_t edma_transfer_config_t::destModulo`

17.2.2.1.0.90.10 `uint32_t edma_transfer_config_t::minorLoopCount`

Number of bytes to be transferred in each service request of the channel.

17.2.2.1.0.90.11 `uint16_t edma_transfer_config_t::majorLoopCount`

17.2.2.2 `struct edma_minorloop_offset_config_t`

Data Fields

- `bool enableSrcMinorloop`
Enable(true) or Disable(false) source minor loop offset.
- `bool enableDestMinorloop`
Enable(true) or Disable(false) destination minor loop offset.
- `uint32_t offset`
Offset for minor loop mapping.

17.2.2.2.0.91 Field Documentation

17.2.2.2.0.91.1 bool `edma_minorloop_offset_config_t::enableSrcMinorloop`

17.2.2.2.0.91.2 bool `edma_minorloop_offset_config_t::enableDestMinorloop`

17.2.2.2.0.91.3 uint32_t `edma_minorloop_offset_config_t::offset`

17.2.2.3 struct `edma_error_status_all_t`

Data Fields

- uint8_t `errorChannel`
Error channel number of the cancelled channel number.
- bool `destinationBusError`
Bus error on destination address.
- bool `sourceBusError`
Bus error on the SRC address.
- bool `scatterOrGatherConfigurationError`
Error on the Scatter/Gather address.
- bool `nbyteOrCiterConfigurationError`
NBYTES/CITER configuration error.
- bool `destinationOffsetError`
Destination offset error.
- bool `destinationAddressError`
Destination address error.
- bool `sourceOffsetError`
Source offset error.
- bool `sourceAddressError`
Source address error.
- bool `channelPriorityError`
Channel priority error.
- bool `transferCancelledError`
Transfer cancelled.
- bool `orOfAllError`
Logical OR all ERR status bits.

17.2.2.4 struct `edma_software_tcd_t`

17.2.3 Enumeration Type Documentation

17.2.3.1 enum `edma_status_t`

Enumerator

kStatus_EDMA_InvalidArgument Parameter is invalid.

kStatus_EDMA_Fail Failed operation.

eDMA HAL driver

17.2.3.2 enum edma_channel_arbitration_t

Enumerator

- kEDMAChnArbitrationFixedPriority* Fixed Priority arbitration is used to select among channels.
- kEDMAChnArbitrationRoundrobin* Round-Robin arbitration is used to select among channels.

17.2.3.3 enum edma_channel_indicator_t

Enumerator

- kEDMAChannel0* Channel 0.

17.2.3.4 enum edma_bandwidth_config_t

Enumerator

- kEDMABandwidthStallNone* No eDMA engine stalls.
- kEDMABandwidthStall4Cycle* eDMA engine stalls for 4 cycles after each read/write.
- kEDMABandwidthStall8Cycle* eDMA engine stalls for 8 cycles after each read/write.

17.2.4 Function Documentation

17.2.4.1 void EDMA_HAL_Init (DMA_Type * *base*)

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for the eDMA module. |
|-------------|--|

17.2.4.2 void EDMA_HAL_CancelTransfer (DMA_Type * *base*)

This function stops the executing channel and forces the minor loop to finish. The cancellation takes effect after the last write of the current read/write sequence. The CX clears itself after the cancellation is complete. The cancellation retires the channel normally as if the minor loop had completed.

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
|-------------|--|

17.2.4.3 void EDMA_HAL_ErrorCancelTransfer (DMA_Type * *base*)

This function stops the executing channel and forces the minor loop to finish. The cancellation takes effect after the last write of the current read/write sequence. The CX clears itself after the cancellation is complete. The cancellation retires the channel normally as if the minor loop had completed and the operation is treated as an error condition.

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
|-------------|--|

17.2.4.4 static void EDMA_HAL_SetHaltCmd (DMA_Type * *base*, bool *halt*) [inline], [static]

This function stalls/continues the start of any new channel. Executing channels are allowed to be completed.

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>halt</i> | Halts (true) or resumes (false) eDMA transfer. |

17.2.4.5 static void EDMA_HAL_SetHaltOnErrorCmd (DMA_Type * *base*, bool *haltOnError*) [inline], [static]

An error causes the halt bit to be set. Subsequently, all service requests are ignored until the halt bit is cleared.

Parameters

| | |
|--------------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>haltOnError</i> | Halts (true) or not halt (false) eDMA module when an error occurs. |

17.2.4.6 static void EDMA_HAL_SetDebugCmd (DMA_Type * *base*, bool *enable*) [inline], [static]

This function enables/disables the eDMA debug mode. When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes either when the

eDMA HAL driver

system exits debug mode or when the EDBG bit is cleared.

Parameters

| | |
|---------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>enable</i> | Enables (true) or Disable (false) eDMA module debug mode. |

17.2.4.7 static void EDMA_HAL_SetChannelPreemptMode (DMA_Type * *base*, uint32_t *channel*, bool *preempt*, bool *preemption*) [inline], [static]

This function sets the preempt and preemption features.

Parameters

| | |
|-------------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>preempt</i> | eDMA channel can't suspend a lower priority channel (true). eDMA channel can suspend a lower priority channel (false). |
| <i>preemption</i> | eDMA channel can be temporarily suspended by the service request of a higher priority channel (true). eDMA channel can't be suspended by a higher priority channel (false). |

17.2.4.8 static void EDMA_HAL_SetChannelPriority (DMA_Type * *base*, uint32_t *channel*, edma_channel_priority_t *priority*) [inline], [static]

Parameters

| | |
|-----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>priority</i> | Priority of the DMA channel. Different channels should have different priority setting inside a group. |

17.2.4.9 static void EDMA_HAL_SetChannelArbitrationMode (DMA_Type * *base*, edma_channel_arbitration_t *channelArbitration*) [inline], [static]

Parameters

eDMA HAL driver

| | |
|----------------------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel-Arbitration</i> | Round-Robin way for fixed priority way. |

17.2.4.10 static void EDMA_HAL_SetMinorLoopMappingCmd (DMA_Type * *base*, bool *enable*) [inline], [static]

This function enables/disables the minor loop mapping feature. If enabled, the NBYTES is redefined to include the individual enable fields and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.

Parameters

| | |
|---------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>enable</i> | Enables (true) or Disable (false) minor loop mapping. |

17.2.4.11 static void EDMA_HAL_SetContinuousLinkCmd (DMA_Type * *base*, bool *continuous*) [inline], [static]

This function enables or disables the continuous transfer. If set, a minor loop channel link does not go through the channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself.

Parameters

| | |
|-------------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>continuous</i> | Enables (true) or Disable (false) continuous transfer mode. |

17.2.4.12 edma_error_status_all_t EDMA_HAL_GetErrorStatus (DMA_Type * *base*)

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
|-------------|--|

Returns

Detailed information of the error type in the eDMA module.

17.2.4.13 void EDMA_HAL_SetErrorIntCmd (DMA_Type * *base*, bool *enable*,
edma_channel_indicator_t *channel*)

eDMA HAL driver

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>enable</i> | Enable(true) or Disable (false) error interrupt. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels' error interrupt will be enabled/disabled. |

17.2.4.14 static uint32_t EDMA_HAL_GetErrorIntStatusFlag (DMA_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
|-------------|--|

Returns

32 bit variable indicating error channels. If error happens on eDMA channel n, the bit n of this variable is '1'. If not, the bit n of this variable is '0'.

17.2.4.15 static void EDMA_HAL_ClearErrorIntStatusFlag (DMA_Type * *base*, edma_channel_indicator_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels' error interrupt status will be cleared. |

17.2.4.16 void EDMA_HAL_SetDmaRequestCmd (DMA_Type * *base*, edma_channel_indicator_t *channel*, bool *enable*)

Parameters

| | |
|-------------|--|
| <i>base</i> | Register base address for eDMA module. |
|-------------|--|

| | |
|----------------|---|
| <i>enable</i> | Enable(true) or Disable (false) DMA request. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels DMA request are enabled/disabled. |

17.2.4.17 static bool EDMA_HAL_GetDmaRequestStatusFlag (DMA_Type * *base*, uint32_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

Hardware request is triggered in this eDMA channel (true) or not be triggered in this channel (false).

17.2.4.18 static void EDMA_HAL_ClearDoneStatusFlag (DMA_Type * *base*, edma_channel_indicator_t *channel*) [inline], [static]

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels' done status will be cleared. |

17.2.4.19 static void EDMA_HAL_TriggerChannelStart (DMA_Type * *base*, edma_channel_indicator_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels are triggered. |

17.2.4.20 static bool EDMA_HAL_GetIntStatusFlag (DMA_Type * *base*, uint32_t *channel*) [inline], [static]

eDMA HAL driver

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

Interrupt request happens in this eDMA channel (true) or not happen in this channel (false).

17.2.4.21 static void EDMA_HAL_ClearIntStatusFlag (DMA_Type * *base*, edma_channel_indicator_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | Channel indicator. If kEDMAAllChannel is selected, all channels' interrupt status will be cleared. |

17.2.4.22 void EDMA_HAL_HTCDClearReg (DMA_Type * *base*, uint32_t *channel*)

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

17.2.4.23 static void EDMA_HAL_HTCDSetSrcAddr (DMA_Type * *base*, uint32_t *channel*, uint32_t *address*) [inline], [static]

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>address</i> | The pointer to the source memory address. |

17.2.4.24 static void EDMA_HAL_HTCDSetSrcOffset (DMA_Type * *base*, uint32_t *channel*, int16_t *offset*) [inline], [static]

Sign-extended offset applied to the current source address to form the next-state value as each source read is complete.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>offset</i> | signed-offset for source address. |

17.2.4.25 void EDMA_HAL_HTCDSetAttribute (DMA_Type * *base*, uint32_t *channel*, edma_modulo_t *srcModulo*, edma_modulo_t *destModulo*, edma_transfer_size_t *srcTransferSize*, edma_transfer_size_t *destTransferSize*)

Parameters

| | |
|------------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>srcModulo</i> | enumeration type for an allowed source modulo. The value defines a specific address range specified as the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of the lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with SMOD function restricting the addresses to a 0-modulo-size range. |

eDMA HAL driver

| | |
|--------------------------|--|
| <i>destModulo</i> | Enum type for an allowed destination modulo. |
| <i>srcTransferSize</i> | Enum type for source transfer size. |
| <i>destTransfer-Size</i> | Enum type for destination transfer size. |

17.2.4.26 void EDMA_HAL_HTCDSetNbytes (DMA_Type * *base*, uint32_t *channel*, uint32_t *nbytes*)

Note here that user need firstly configure the minor loop mapping feature and then call this function.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>nbytes</i> | Number of bytes to be transferred in each service request of the channel |

17.2.4.27 uint32_t EDMA_HAL_HTCDGetNbytes (DMA_Type * *base*, uint32_t *channel*)

This function decides whether the minor loop mapping is enabled or whether the source/destination minor loop mapping is enabled. Then, the nbytes are returned accordingly.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

nbytes configuration according to minor loop setting.

17.2.4.28 void EDMA_HAL_HTCDSetMinorLoopOffset (DMA_Type * *base*, uint32_t *channel*, edma_minorloop_offset_config_t * *config*)

Configures both the enable bits and the offset value. If neither source nor destination offset is enabled, the offset is not configured. Note here if source or destination offset is required, the eDMA module EMLM bit is set in this function.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>config</i> | Configuration data structure for the minor loop offset |

17.2.4.29 static void EDMA_HAL_HTCDSetSrcLastAdjust (DMA_Type * *base*, uint32_t *channel*, int32_t *size*) [inline], [static]

Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>size</i> | adjustment value |

17.2.4.30 static void EDMA_HAL_HTCDSetDestAddr (DMA_Type * *base*, uint32_t *channel*, uint32_t *address*) [inline], [static]

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>address</i> | The pointer to the destination address. |

17.2.4.31 static void EDMA_HAL_HTCDSetDestOffset (DMA_Type * *base*, uint32_t *channel*, int16_t *offset*) [inline], [static]

Sign-extended offset applied to the current source address to form the next-state value as each destination write is complete.

Parameters

eDMA HAL driver

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>offset</i> | signed-offset |

17.2.4.32 **static void EDMA_HAL_HTCDSetDestLastAdjust (DMA_Type * *base*, uint32_t *channel*, uint32_t *adjust*) [inline], [static]**

This function adds an adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>adjust</i> | adjustment value |

17.2.4.33 **void EDMA_HAL_HTCDSetScatterGatherLink (DMA_Type * *base*, uint32_t *channel*, edma_software_tcd_t * *stcd*)**

This function enables the scatter/gather feature for the hardware TCD and configures the next TCD's address. This address points to the beginning of a 0-modulo-32 byte region containing the next transfer TCD to be loaded into this channel. The channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte. Otherwise, a configuration error is reported.

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>stcd</i> | The pointer to the TCD to be linked to this hardware TCD. |

17.2.4.34 **static void EDMA_HAL_HTCDSetBandwidth (DMA_Type * *base*, uint32_t *channel*, edma_bandwidth_config_t *bandwidth*) [inline], [static]**

Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.

Parameters

| | |
|------------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>bandwidth</i> | enum type for bandwidth control |

17.2.4.35 `static void EDMA_HAL_HTCDSetChannelMajorLink (DMA_Type * base,
uint32_t channel, uint32_t majorChannel, bool enable) [inline],
[static]`

If the major link is enabled, after the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel start bits.

Parameters

| | |
|---------------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>majorChannel</i> | channel number for major link |
| <i>enable</i> | Enables (true) or Disables (false) channel major link. |

17.2.4.36 `static void EDMA_HAL_HTCDSetScatterGatherCmd (DMA_Type * base,
uint32_t channel, bool enable) [inline], [static]`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>enable</i> | Enables (true) /Disables (false) scatter/gather feature. |

17.2.4.37 `static void EDMA_HAL_HTCDSetDisableDmaRequestAfterTCDDoneCmd (
DMA_Type * base, uint32_t channel, bool disable) [inline], [static]`

If disabled, the eDMA hardware automatically clears the corresponding DMA request when the current major iteration count reaches zero.

eDMA HAL driver

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>disable</i> | Disable (true)/Enable (true) DMA request after TCD complete. |

17.2.4.38 static void EDMA_HAL_HTCDSetHalfCompleteIntCmd (DMA_Type * *base*, uint32_t *channel*, bool *enable*) [inline], [static]

If set, the channel generates an interrupt request by setting the appropriate bit in the interrupt register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This half-way point interrupt request is provided to support the double-buffered schemes or other types of data movement where the processor needs an early indication of the transfer's process.

Parameters

| | |
|----------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>enable</i> | Enable (true) /Disable (false) half complete interrupt. |

17.2.4.39 static void EDMA_HAL_HTCDSetIntCmd (DMA_Type * *base*, uint32_t *channel*, bool *enable*) [inline], [static]

If enabled, the channel generates an interrupt request by setting the appropriate bit in the interrupt register when the current major iteration count reaches zero.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>enable</i> | Enable (true) /Disable (false) interrupt after TCD done. |

17.2.4.40 static void EDMA_HAL_HTCDTriggerChannelStart (DMA_Type * *base*, uint32_t *channel*) [inline], [static]

The eDMA hardware automatically clears this flag after the channel begins execution.

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

17.2.4.41 static bool EDMA_HAL_HTCDGetChannelActiveStatus (DMA_Type * *base*, uint32_t *channel*) [inline], [static]

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

True stands for running. False stands for not.

17.2.4.42 void EDMA_HAL_HTCDSetChannelMinorLink (DMA_Type * *base*, uint32_t *channel*, uint32_t *linkChannel*, bool *enable*)

Parameters

| | |
|--------------------|---|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>linkChannel</i> | Channel to be linked on minor loop complete. |
| <i>enable</i> | Enable (true)/Disable (false) channel minor link. |

17.2.4.43 void EDMA_HAL_HTCDSetMajorCount (DMA_Type * *base*, uint32_t *channel*, uint32_t *count*)

Note here that user need to first set the minor loop channel link and then call this function. The execute flow inside this function is dependent on the minor loop channel link setting.

Parameters

eDMA HAL driver

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>count</i> | major loop count |

17.2.4.44 `uint32_t EDMA_HAL_HTCDGetFinishedBytes (DMA_Type * base, uint32_t channel)`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

data bytes already transferred

17.2.4.45 `uint32_t EDMA_HAL_HTCDGetUnfinishedBytes (DMA_Type * base, uint32_t channel)`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

data bytes already transferred

17.2.4.46 `static bool EDMA_HAL_HTCDGetDoneStatusFlag (DMA_Type * base, uint32_t channel) [inline], [static]`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

If channel done.

17.2.4.47 `uint32_t EDMA_HAL_HTCDGetBeginMajorCount (DMA_Type * base, uint32_t channel)`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

Begin major count of this channel.

17.2.4.48 `uint32_t EDMA_HAL_HTCDGetCurrentMajorCount (DMA_Type * base, uint32_t channel)`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |

Returns

Current major count of this channel.

17.2.4.49 `static void EDMA_HAL_STCDSetSrcAddr (edma_software_tcd_t * stcd, uint32_t address) [inline], [static]`

eDMA HAL driver

Parameters

| | |
|----------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>address</i> | The source memory address. |

17.2.4.50 `static void EDMA_HAL_STCDSetSrcOffset (edma_software_tcd_t * stcd, int16_t offset) [inline], [static]`

Sign-extended offset applied to the current source address to form the next-state value as each source read is complete.

Parameters

| | |
|---------------|-----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>offset</i> | signed-offset for source address. |

17.2.4.51 `void EDMA_HAL_STCDSetAttribute (edma_software_tcd_t * stcd, edma_modulo_t srcModulo, edma_modulo_t destModulo, edma_transfer_size_t srcTransferSize, edma_transfer_size_t destTransferSize)`

Parameters

| | |
|------------------|--|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>srcModulo</i> | enum type for an allowed source modulo. The value defines a specific address range specified as the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of the lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with SMOD function restricting the addresses to a 0-modulo-size range. |

| | |
|--------------------------|--|
| <i>destModulo</i> | Enum type for an allowed destination modulo. |
| <i>srcTransferSize</i> | Enum type for source transfer size. |
| <i>destTransfer-Size</i> | Enum type for destination transfer size. |

17.2.4.52 void EDMA_HAL_STCDSetNbytes (DMA_Type * *base*, edma_software_tcd_t * *stcd*, uint32_t *nbytes*)

Note here that user need firstly configure the minor loop mapping feature and then call this function.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>stcd</i> | The pointer to the software TCD. |
| <i>nbytes</i> | Number of bytes to be transferred in each service request of the channel |

17.2.4.53 void EDMA_HAL_STCDSetMinorLoopOffset (DMA_Type * *base*, edma_software_tcd_t * *stcd*, edma_minorloop_offset_config_t * *config*)

Configures both the enable bits and the offset value. If neither source nor destination offset is enabled, the offset is not configured. Note, if either the source or the destination offset is required, the eDMA module EMLM bit is set in this function.

Parameters

| | |
|---------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>stcd</i> | The pointer to the software TCD. |
| <i>config</i> | Configuration data structure for the minor loop offset |

17.2.4.54 static void EDMA_HAL_STCDSetSrcLastAdjust (edma_software_tcd_t * *stcd*, int32_t *size*) [inline], [static]

Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.

eDMA HAL driver

Parameters

| | |
|-------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>size</i> | adjustment value |

17.2.4.55 `static void EDMA_HAL_STCDSetDestAddr (edma_software_tcd_t * stcd, uint32_t address) [inline], [static]`

Parameters

| | |
|----------------|---|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>address</i> | The pointer to the destination address. |

17.2.4.56 `static void EDMA_HAL_STCDSetDestOffset (edma_software_tcd_t * stcd, int16_t offset) [inline], [static]`

Sign-extended offset applied to the current source address to form the next-state value as the each destination write is complete.

Parameters

| | |
|---------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>offset</i> | signed-offset |

17.2.4.57 `static void EDMA_HAL_STCDSetDestLastAdjust (edma_software_tcd_t * stcd, uint32_t adjust) [inline], [static]`

This function add an adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.

Parameters

| | |
|---------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>adjust</i> | adjustment value |

17.2.4.58 void EDMA_HAL_STCDSetScatterGatherLink (edma_software_tcd_t * *stcd*, edma_software_tcd_t * *nextStcd*)

This function enable the scatter/gather feature for the software TCD and configure the next TCD's address. This address points to the beginning of a 0-modulo-32 byte region containing the next transfer TCD to be loaded into this channel. The channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte. Otherwise, a configuration error is reported.

Parameters

| | |
|-----------------|---|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>nextStcd</i> | The pointer to the TCD to be linked to this software TCD. |

17.2.4.59 static void EDMA_HAL_STCDSetBandwidth (edma_software_tcd_t * *stcd*, edma_bandwidth_config_t *bandwidth*) [inline], [static]

Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.

Parameters

| | |
|------------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>bandwidth</i> | enum type for bandwidth control |

17.2.4.60 static void EDMA_HAL_STCDSetChannelMajorLink (edma_software_tcd_t * *stcd*, uint32_t *majorChannel*, bool *enable*) [inline], [static]

If the major link is enabled, after the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel start bits.

Parameters

| | |
|-------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
|-------------|----------------------------------|

eDMA HAL driver

| | |
|---------------------|--|
| <i>majorChannel</i> | channel number for major link |
| <i>enable</i> | Enables (true) or Disables (false) channel major link. |

17.2.4.61 `static void EDMA_HAL_STCDSetScatterGatherCmd (edma_software_tcd_t * stcd, bool enable) [inline], [static]`

Parameters

| | |
|---------------|--|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>enable</i> | Enables (true) /Disables (false) scatter/gather feature. |

17.2.4.62 `static void EDMA_HAL_STCDSetDisableDmaRequestAfterTCDDoneCmd (edma_software_tcd_t * stcd, bool disable) [inline], [static]`

If disabled, the eDMA hardware automatically clears the corresponding DMA request when the current major iteration count reaches zero.

Parameters

| | |
|----------------|--|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>disable</i> | Disable (true)/Enable (true) DMA request after TCD complete. |

17.2.4.63 `static void EDMA_HAL_STCDSetHalfCompleteIntCmd (edma_software_tcd_t * stcd, bool enable) [inline], [static]`

If set, the channel generates an interrupt request by setting the appropriate bit in the interrupt register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This half-way point interrupt request is provided to support the double-buffered schemes or other types of data movement where the processor needs an early indication of the transfer's process.

Parameters

| | |
|---------------|---|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>enable</i> | Enable (true) /Disable (false) half complete interrupt. |

17.2.4.64 static void EDMA_HAL_STCDSetIntCmd (edma_software_tcd_t * *stcd*, bool *enable*) [inline], [static]

If enabled, the channel generates an interrupt request by setting the appropriate bit in the interrupt register when the current major iteration count reaches zero.

Parameters

| | |
|---------------|--|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>enable</i> | Enable (true) /Disable (false) interrupt after TCD done. |

17.2.4.65 static void EDMA_HAL_STCDTriggerChannelStart (edma_software_tcd_t * *stcd*) [inline], [static]

The eDMA hardware automatically clears this flag after the channel begins execution.

Parameters

| | |
|-------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
|-------------|----------------------------------|

17.2.4.66 void EDMA_HAL_STCDSetChannelMinorLink (edma_software_tcd_t * *stcd*, uint32_t *linkChannel*, bool *enable*)

Parameters

| | |
|--------------------|---|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>linkChannel</i> | Channel to be linked on minor loop complete. |
| <i>enable</i> | Enable (true)/Disable (false) channel minor link. |

17.2.4.67 void EDMA_HAL_STCDSetMajorCount (edma_software_tcd_t * *stcd*, uint32_t *count*)

The user needs to set the minor loop channel link first and then call this function. The execution flow inside this function is dependent on the minor loop channel link setting.

eDMA HAL driver

Parameters

| | |
|--------------|----------------------------------|
| <i>stcd</i> | The pointer to the software TCD. |
| <i>count</i> | major loop count |

17.2.4.68 `void EDMA_HAL_PushSTCDToHTCD (DMA_Type * base, uint32_t channel, edma_software_tcd_t * stcd)`

Parameters

| | |
|----------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>channel</i> | eDMA channel number. |
| <i>stcd</i> | The pointer to the software TCD. |

17.2.4.69 `edma_status_t EDMA_HAL_STCDSetBasicTransfer (DMA_Type * base, edma_software_tcd_t * stcd, edma_transfer_config_t * config, bool enableInt, bool disableDmaRequest)`

This function is used to set up the basic transfer for software TCD. The minor loop setting is not involved here because the minor loop's configuration has an impact on the global eDMA setting and the source minor loop offset is relevant to the destination minor loop offset. For these reasons, the minor loop offset configuration is treated as an advanced configuration. The user can call the [EDMA_HAL_STCDSetMinorLoopOffset\(\)](#) to configure the minor loop offset feature.

Parameters

| | |
|--------------------------|--|
| <i>base</i> | Register base address for eDMA module. |
| <i>stcd</i> | The pointer to the software TCD. |
| <i>config</i> | The pointer to the transfer configuration structure. |
| <i>enableInt</i> | Enables (true) or Disables (false) interrupt on TCD complete. |
| <i>disableDmaRequest</i> | Disables (true) or Enable (false) DMA request on TCD complete. |

Returns

An eDMA error codes or `kStatus_EDMA_Success`.

17.3 eDMA Peripheral driver

17.3.1 Overview

This chapter describes the programming interface of the eDMA Peripheral driver. The eDMA driver requests, configures, and uses eDMA hardware. It supports module initializations and DMA channel configurations.

17.3.2 eDMA Initialization

To initialize the DMA module, call the [EDMA_DRV_Init\(\)](#) function. The user does not need to pass a configuration data structure. This function enables the eDMA module and clock automatically.

17.3.3 eDMA Channel concept

The eDMA module has many channels. Additionally, the EDMA peripheral driver is designed based on a channel concept. All operations should be started by requesting an eDMA channel and ended by freeing an eDMA channel. The user can configure and run operations on the eDMA module by allocating a channel. If a channel is not allocated, a system error may occur.

17.3.4 DMA request concept

A DMA request triggers an eDMA transfer. The DMA request table is available in device configuration chapters in a device reference manual.

17.3.5 eDMA Memory allocation and alignment

The eDMA peripheral driver does not allocate memory dynamically. The user needs to provide the allocated memory pointer for the driver and ensure that the memory is valid. Otherwise, a system error may occur. Prepare three types of memory:

1. The handler memory: [edma_channel_t]. The driver must store the status data for each channel. The edma_channel_t is designed for this purpose.
2. The [edma_software_tcd_t](#). The eDMA supports a TCD chain, which provides either the scatter-gather feature or the loop feature. The eDMA module loads the TCDs from memory, where TCDs are stored. The user must provide the memory storing software TCDs and the [EDMA_DRV_ConfigScatterGatherTransfer\(\)](#) function or the [EDMA_DRV_ConfigLoopTransfer\(\)](#) function to configure the software TCDs. If those functions fail to configure the software TCDs, use the [EDMA_DRV_V_PrepareDescriptorTransfer\(\)](#) function to configure the TCD. Then, call the [EDMA_DRV_PushDescriptorToReg\(\)](#) function to push the TCD to registers.

eDMA Peripheral driver

3. The status memory. To get the status of the TCD chains, provide the status memory, which the driver fills with chain status.

The start address of the software TCDs must be 32 bytes.

17.3.6 eDMA Call diagram

To use the DMA driver, follow these steps:

1. Initialize the DMA module: `EDMA_DRV_Init()`.
2. Request a DMA channel: `EDMA_DRV_RequestChannel()`.
3. Configure the TCD:
 - Configure the TCD chain in a scatter-gather list. UART transmit/receive is the common case.
 - Configure the TCD chain in a loop way. Audio playback/Record is the common case.
 - Configure software TCD and push it to registers. Use the DSPI case to configure and push the TCD to registers.
4. Register callback function: `EDMA_DRV_InstallCallback`.
5. Start the DMA channel: `EDMA_DRV_StartChannel`.
6. [OPTION] Stop the DMA channel: `EDMA_DRV_StopChannel`.
7. Free the DMA channel: `EDMA_DRV_ReleaseChannel`.

This is an example code to initialize and configure the driver by configuring the descriptor:

```
EDMA_DRV_Init();

stcd = (edma_software_tcd_t *)(((uint32_t)status + 32) & ~0x1F);

// Prepare the memory space. //
for ( i = 0; i < kEdmaTestChainLength; i++)
{
    // Allocate the memory! //
    srcAddr[i] = malloc(kEdmaTestBufferSize);
    destAddr[i] = malloc(kEdmaTestBufferSize);

    // Check whether the allocation is successfully. //
    if (((uint32_t)srcAddr[i] == 0x0U) & ((uint32_t)destAddr[i] == 0x0U))
    {
        printf("Fali to allocate memory for EDMA test! \r\n");
        goto error;
    }

    // Init the memory buffer. //
    for ( j = 0; j < kEdmaTestBufferSize; j++)
    {
        srcAddr[i][j] = j;
        destAddr[i][j] = 0;
    }

    srcSG[i].address = (uint32_t)srcAddr[i];
    destSG[i].address = (uint32_t)destAddr[i];
    srcSG[i].length = kEdmaTestBufferSize;
    destSG[i].length = kEdmaTestBufferSize;
}

if (EDMA_DRV_RequestChannel(channel, kDmaRequestMux0AlwaysOn62, &chan_handler) !=
    channel)
{
```

```

printf("Failed to request channel %d !\r\n", channel);
goto error;
}

EDMA_DRV_ConfigScatterGatherTransfer(
    stcd, &chan_handler, kDmaMemoryToMemory,
    0x1U, kEdmaTestWatermarkLevel,
    srcSG, destSG,
    kEdmaTestChainLength);

EDMA_DRV_InstallCallback(&chan_handler, test_callback, &chan_handler);

EDMA_DRV_StartChannel(&chan_handler);

```

For an example to configure the loop mode, see the SAI module driver.

17.3.7 eDMA Extend the driver

The user can call the eDMA HAL driver to extend the application capability.

Data Structures

- struct [edma_user_config_t](#)
The user configuration structure for the eDMA driver. [More...](#)
- struct [edma_chn_state_t](#)
Data structure for the eDMA channel. [More...](#)
- struct [edma_scatter_gather_list_t](#)
Data structure for configuring a discrete memory transfer. [More...](#)
- struct [edma_state_t](#)
Runtime state structure for the eDMA driver. [More...](#)

Macros

- #define [STCD_SIZE](#)(number) ((number + 1) * 32)
Macro for the memory size needed for the software TCD.
- #define [VIRTUAL_CHN_TO_EDMA_MODULE_REGBASE](#)(chn) [g_edmaBase](#)[chn/FSL_FEATURE_EDMA_MODULE_CHANNEL]
Macro to get the eDMA physical module indicator from the virtual channel indicator.
- #define [VIRTUAL_CHN_TO_EDMA_CHN](#)(chn) (chn%FSL_FEATURE_EDMA_MODULE_CHANNEL)
Macro to get the eDMA physical channel indicator from the virtual channel indicator.
- #define [VIRTUAL_CHN_TO_DMAMUX_MODULE_REGBASE](#)(chn) [g_dmamuxBase](#)[chn/FSL_FEATURE_DMAMUX_MODULE_CHANNEL]
Macro to get the DMAMUX physical module indicator from the virtual channel indicator.
- #define [VIRTUAL_CHN_TO_DMAMUX_CHN](#)(chn) (chn%FSL_FEATURE_DMAMUX_MODULE_CHANNEL)
Macro to get the DMAMUX physical channel indicator from the virtual channel indicator.

eDMA Peripheral driver

Typedefs

- typedef void(* [edma_callback_t](#))(void *parameter, [edma_chn_status_t](#) status)
Definition for the eDMA channel callback function.

Enumerations

- enum [edma_chn_status_t](#) {
 [kEDMAChnNormal](#) = 0U,
 [kEDMAChnIdle](#),
 [kEDMAChnError](#) }
Channel status for eDMA channel.
- enum [edma_chn_state_type_t](#) {
 [kEDMAInvalidChannel](#) = 0xFFU,
 [kEDMAAnyChannel](#) = 0xFEU }
enum type for channel allocation.
- enum [edma_transfer_type_t](#) {
 [kEDMAPeripheralToMemory](#),
 [kEDMAMemoryToPeripheral](#),
 [kEDMAMemoryToMemory](#) }
A type for the DMA transfer.

Variables

- DMA_Type *const [g_edmaBase](#) []
Array for the eDMA module register base address.
- DMAMUX_Type *const [g_dmamuxBase](#) []
Array for DMAMUX module register base address.
- const IRQn_Type [g_edmaIrqId](#) [DMA_INSTANCE_COUNT][FSL_FEATURE_EDMA_MODULE_CHANNEL]
Two dimensional array for eDMA channel interrupt vector number.
- const IRQn_Type [g_edmaErrIrqId](#) [DMA_INSTANCE_COUNT]
Array for eDMA module's error interrupt vector number.

eDMA peripheral driver module level functions

- [edma_status_t](#) [EDMA_DRV_Init](#) ([edma_state_t](#) *edmaState, const [edma_user_config_t](#) *user-Config)
Initializes all eDMA modules in an SOC.
- [edma_status_t](#) [EDMA_DRV_Deinit](#) (void)
Shuts down all eDMA modules.

eDMA peripheral driver channel management functions

- `uint8_t EDMA_DRV_RequestChannel` (`uint8_t channel`, `dma_request_source_t source`, `edma_chn_state_t *chn`)
Requests an eDMA channel dynamically or statically.
- `edma_status_t EDMA_DRV_ReleaseChannel` (`edma_chn_state_t *chn`)
Releases an eDMA channel.

eDMA peripheral driver transfer setup functions

- static `edma_status_t EDMA_DRV_PrepareDescriptorTransfer` (`edma_chn_state_t *chn`, `edma_software_tcd_t *stcd`, `edma_transfer_config_t *config`, `bool enableInt`, `bool disableDmaRequest`)
Sets the descriptor basic transfer for the descriptor.
- static `edma_status_t EDMA_DRV_PrepareDescriptorScatterGather` (`edma_software_tcd_t *stcd`, `edma_software_tcd_t *nextStcd`)
Configures the memory address for the next transfer TCD for the software TCD.
- static `edma_status_t EDMA_DRV_PrepareDescriptorChannelLink` (`edma_software_tcd_t *stcd`, `uint32_t linkChn`)
Configures the major channel link the software TCD.
- static `edma_status_t EDMA_DRV_PrepareDescriptorMinorLink` (`edma_software_tcd_t *stcd`, `uint32_t linkChn`)
Configures the minor channel link the software TCD.
- static `edma_status_t EDMA_DRV_TriggerChannelStart` (`edma_chn_state_t *chn`)
Triggers the eDMA channel.
- `edma_status_t EDMA_DRV_PushDescriptorToReg` (`edma_chn_state_t *chn`, `edma_software_tcd_t *stcd`)
Copies the software TCD configuration to the hardware TCD.
- `edma_status_t EDMA_DRV_ConfigLoopTransfer` (`edma_chn_state_t *chn`, `edma_software_tcd_t *stcd`, `edma_transfer_type_t type`, `uint32_t srcAddr`, `uint32_t destAddr`, `uint32_t size`, `uint32_t bytesOnEachRequest`, `uint32_t totalLength`, `uint8_t number`)
Configures the DMA transfer in a scatter-gather mode.
- `edma_status_t EDMA_DRV_ConfigScatterGatherTransfer` (`edma_chn_state_t *chn`, `edma_software_tcd_t *stcd`, `edma_transfer_type_t type`, `uint32_t size`, `uint32_t bytesOnEachRequest`, `edma_scatter_gather_list_t *srcList`, `edma_scatter_gather_list_t *destList`, `uint8_t number`)
Configures the DMA transfer in a scatter-gather mode.

eDMA Peripheral driver channel operation functions

- `edma_status_t EDMA_DRV_StartChannel` (`edma_chn_state_t *chn`)
Starts an eDMA channel.
- `edma_status_t EDMA_DRV_StopChannel` (`edma_chn_state_t *chn`)
Stops the eDMA channel.

eDMA Peripheral driver

eDMA Peripheral callback and interrupt functions

- `edma_status_t` `EDMA_DRV_InstallCallback` (`edma_chn_state_t *chn`, `edma_callback_t` `callback`, `void *parameter`)
Registers the callback function and the parameter for eDMA channel.
- `void` `EDMA_DRV_IRQHandler` (`uint8_t` `channel`)
IRQ Handler for eDMA channel interrupt.
- `void` `EDMA_DRV_ErrorIRQHandler` (`uint8_t` `instance`)
ERROR IRQ Handler for eDMA channel interrupt.

eDMA Peripheral driver miscellaneous functions

- `static edma_chn_status_t` `EDMA_DRV_GetChannelStatus` (`edma_chn_state_t *chn`)
Gets the eDMA channel status.
- `static uint32_t` `EDMA_DRV_GetUnfinishedBytes` (`edma_chn_state_t *chn`)
Gets the unfinished bytes for the eDMA channel current TCD.
- `static uint32_t` `EDMA_DRV_GetFinishedBytes` (`edma_chn_state_t *chn`)
Gets the bytes already transferred for the eDMA channel current TCD.

17.3.8 Data Structure Documentation

17.3.8.1 struct edma_user_config_t

Use an instance of this structure with the `EDMA_DRV_Init()` function. This allows the user to configure settings of the EDMA peripheral with a single function call.

Data Fields

- `edma_channel_arbitration_t` `chnArbitration`
eDMA channel arbitration.
- `bool` `notHaltOnError`
Any error causes the HALT bit to set.

17.3.8.1.0.92 Field Documentation

17.3.8.1.0.92.1 bool edma_user_config_t::notHaltOnError

Subsequently, all service requests are ignored until the HALT bit is cleared.

17.3.8.2 struct edma_chn_state_t

Data Fields

- `uint8_t` `channel`
Virtual channel indicator.

- `edma_callback_t` `callback`
Callback function pointer for the eDMA channel.
- `void *` `parameter`
Parameter for the callback function pointer.
- `volatile edma_chn_status_t` `status`
eDMA channel status.

17.3.8.2.0.93 Field Documentation

17.3.8.2.0.93.1 `uint8_t edma_chn_state_t::channel`

17.3.8.2.0.93.2 `edma_callback_t edma_chn_state_t::callback`

It will be called at the eDMA channel complete and eDMA channel error.

17.3.8.2.0.93.3 `void* edma_chn_state_t::parameter`

17.3.8.2.0.93.4 `volatile edma_chn_status_t edma_chn_state_t::status`

17.3.8.3 `struct edma_scatter_gather_list_t`

Data Fields

- `uint32_t` `address`
Address of buffer.
- `uint32_t` `length`
Length of buffer.

17.3.8.3.0.94 Field Documentation

17.3.8.3.0.94.1 `uint32_t edma_scatter_gather_list_t::address`

17.3.8.3.0.94.2 `uint32_t edma_scatter_gather_list_t::length`

17.3.8.4 `struct edma_state_t`

This structure holds data that is used by the eDMA peripheral driver to manage multi eDMA channels. The user passes the memory for this run-time state structure and the eDMA driver populates the members.

Data Fields

- `edma_chn_state_t *volatile chn` [FSL_FEATURE_EDMA_DMAMUX_CHANNELS]
Pointer array storing channel state.

eDMA Peripheral driver

17.3.8.4.0.95 Field Documentation

17.3.8.4.0.95.1 `edma_chn_state_t* volatile edma_state_t::chn[FSL_FEATURE_EDMA_DMAMUX_CHANNELS]`

17.3.9 Macro Definition Documentation

17.3.9.1 `#define STCD_SIZE(number) ((number + 1) * 32)`

Software TCD is aligned to 32 bytes. To make sure the software TCD can meet the eDMA module requirement, allocate memory with extra 32 bytes.

17.3.9.2 `#define VIRTUAL_CHN_TO_EDMA_MODULE_REGBASE(chn) g_edmaBase[chn/FSL_FEATURE_EDMA_MODULE_CHANNEL]`

17.3.9.3 `#define VIRTUAL_CHN_TO_EDMA_CHN(chn) (chn%FSL_FEATURE_EDMA_MODULE_CHANNEL)`

17.3.9.4 `#define VIRTUAL_CHN_TO_DMAMUX_MODULE_REGBASE(chn) g_dmamuxBase[chn/FSL_FEATURE_DMAMUX_MODULE_CHANNEL]`

17.3.9.5 `#define VIRTUAL_CHN_TO_DMAMUX_CHN(chn) (chn%FSL_FEATURE_DMAMUX_MODULE_CHANNEL)`

17.3.10 Typedef Documentation

17.3.10.1 `typedef void(* edma_callback_t)(void *parameter, edma_chn_status_t status)`

Prototype for the callback function registered in the eDMA driver.

17.3.11 Enumeration Type Documentation

17.3.11.1 `enum edma_chn_status_t`

A structure describing the eDMA channel status. The user can get the status by callback parameter or by calling `EDMA_DRV_getStatus()` function.

Enumerator

kEDMAChnNormal eDMA channel is occupied.

kEDMAChnIdle eDMA channel is idle.

kEDMAChnError An error occurs in the eDMA channel.

17.3.11.2 enum edma_chn_state_type_t

Enumerator

kEDMAInvalidChannel Macros indicate the failure of the channel request.

kEDMAAnyChannel Macros used when requesting channel dynamically.

17.3.11.3 enum edma_transfer_type_t

Enumerator

kEDMAPeripheralToMemory Transfer from peripheral to memory.

kEDMAMemoryToPeripheral Transfer from memory to peripheral.

kEDMAMemoryToMemory Transfer from memory to memory.

17.3.12 Function Documentation

17.3.12.1 edma_status_t EDMA_DRV_Init (edma_state_t * edmaState, const edma_user_config_t * userConfig)

This function initializes the run-time state structure to provide the eDMA channel allocation release, protect, and track the state for channels. This function also opens the clock to the eDMA modules, resets the eDMA modules, initializes the module to user-defined settings and default settings. This is an example to set up the `edma_state_t` and the `edma_user_config_t` parameters and to call the `EDMA_DRV_Init` function by passing in these parameters.

```
edma_state_t state;    <- The user simply allocates memory for this structure.
edma_user_config_t userConfig;  <- The user fills out members for this structure.

userConfig.chnArbitration = kEDMAChnArbitrationRoundrobin;
#if (FSL_FEATURE_EDMA_CHANNEL_GROUP_COUNT > 0x1U)
//configuration for 2 lines below only valid for SoCs with more than on group.
userConfig.groupArbitration = kEDMAGroupArbitrationFixedPriority;
userConfig.groupPriority = kEDMAGroup0PriorityHighGroup1PriorityLow;
#endif
userConfig.notHaltOnError = false;    <- The default setting is false, means eDMA halt on
error.

EDMA_DRV_Init(&state, &userConfig);
```

Parameters

eDMA Peripheral driver

| | |
|-------------------|--|
| <i>edmaState</i> | The pointer to the eDMA peripheral driver state structure. The user passes the memory for this run-time state structure and the eDMA peripheral driver populates the members. This run-time state structure keeps track of the eDMA channels status. The memory must be kept valid before calling the EDMA_DRV_DeInit. |
| <i>userConfig</i> | User configuration structure for eDMA peripheral drivers. The user populates the members of this structure and passes the pointer of this structure into the function. |

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.2 edma_status_t EDMA_DRV_Deinit (void)

This function resets the eDMA modules to reset state, gates the clock, and disables the interrupt to the core.

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.3 uint8_t EDMA_DRV_RequestChannel (uint8_t channel, dma_request_source_t source, edma_chn_state_t * chn)

This function allocates the eDMA channel according to the required channel allocation and corresponding to the eDMA hardware request, initializes the channel state memory provided by user and fills out the members. This functions also sets up the hardware request configuration according to the user's requirements.

For Kinetis devices, a hardware request can be mapped to eDMA channels and used for the channel trigger. Some hardware requests can only be mapped to a limited channels. For example, the Kinetis K70FN1-M0VMJ15 device eDMA module has 2 eDMA channel groups. The first group consists of the channel 0 - 15. The second group consists of channel 16 - 31. The hardware request UART0-Receive can be only mapped to group 1. Therefore, the hardware request is one of the parameter that the user needs to provide for the channel request. Channel needn't be triggered by the peripheral hardware request. The user can provide the ALWAYSON type hardware request to trigger the channel continuously.

This function provides two ways to allocate an eDMA channel: statically and dynamically. In a static allocation, the user provides the required channel number and eDMA driver tries to allocate the required channel to the user. If the channel is not occupied, the eDMA driver is successfully assigned to the user. If the channel is already occupied, the user gets the return value kEDMAInvalidChn. This is an example to request a channel statically:

```
uint32_t channelNumber = 14;  <- Try to allocate the channel 14
edma_chn_state_t chn; <- The user simply allocates memory for this structure.
```

```
if ( kEDMAInvalidChannel == EDMA_DRV_RequestChannel(channel,
    kDmaRequestMux0AlwaysOn54, chn))
{
    printf("request channel %d failed!\n", channel);
}
```

In a dynamic allocation, any of the free eDMA channels are available for use. eDMA driver assigns the first free channel to the user. This is an example for user to request a channel dynamically :

```
uint32_t channel;    <- Store the allocated channel number.
edma_chn_state_t chn;    <- The user simply allocates memory for this structure.

channel = EDMA_DRV_RequestChannel(kEDMAAnyChannel,
    kDmaRequestMux0AlwaysOn54, chn);

if (channel == kEDMAInvalidChannel)
{
    printf("request channel %d failed!\n", channel);
}
else
{
    printf("Channel %d is successfully allocated! /n", channel);
}
```

Parameters

| | |
|----------------|--|
| <i>channel</i> | Requested channel number. If the channel is assigned with the kEDMAAnyChannel, the eDMA driver allocates the channel dynamically. If the channel is assigned with a valid channel number, the eDMA driver allocates that channel. |
| <i>source</i> | eDMA hardware request number. |
| <i>chn</i> | The pointer to the eDMA channel state structure. The user passes the memory for this run-time state structure. The eDMA peripheral driver populates the members. This run-time state structure keeps tracks of the eDMA channel status. The memory must be kept valid before calling the EDMA_DRV_ReleaseChannel() . |

Returns

Successfully allocated channel number or the kEDMAInvalidChannel indicating that the request is failed.

17.3.12.4 edma_status_t EDMA_DRV_ReleaseChannel (edma_chn_state_t * chn)

This function stops the eDMA channel and disables the interrupt of this channel. The channel state structure can be released after this function is called.

eDMA Peripheral driver

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

An eDMA error codes or `kStatus_EDMA_Success`.

17.3.12.5 static edma_status_t EDMA_DRV_PrepareDescriptorTransfer (edma_chn_state_t * *chn*, edma_software_tcd_t * *stcd*, edma_transfer_config_t * *config*, bool *enableInt*, bool *disableDmaRequest*) [inline], [static]

This function sets up the basic transfer for the descriptor. The minor loop setting is not used because the minor loop configuration impacts the global eDMA setting. The source minor loop offset is relevant to the destination minor loop offset. For these reasons, the minor loop offset configuration is treated as an advanced configuration. The user can call the [EDMA_HAL_STCDSetMinorLoopOffset\(\)](#) function to configure the minor loop offset feature.

Parameters

| | |
|---------------------------|--|
| <i>channel</i> | Virtual channel number. |
| <i>chn</i> | The pointer to the channel state structure. |
| <i>stcd</i> | The pointer to the descriptor. |
| <i>config</i> | Configuration for the basic transfer. |
| <i>enableInt</i> | Enables (true) or Disables (false) interrupt on TCD complete. |
| <i>disableDma-Request</i> | Disables (true) or Enable (false) DMA request on TCD complete. |

Returns

An eDMA error codes or `kStatus_EDMA_Success`.

17.3.12.6 static edma_status_t EDMA_DRV_PrepareDescriptorScatterGather (edma_software_tcd_t * *stcd*, edma_software_tcd_t * *nextStcd*) [inline], [static]

This function enables the scatter/gather feature for the software TCD and configures the next TCD address. This address points to the beginning of a 0-modulo-32 byte region containing the next transfer TCD to be loaded into this channel. The channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte. Otherwise, a configuration error is reported.

Parameters

| | |
|-----------------|--|
| <i>stcd</i> | The pointer to the software TCD, which needs to link to the software TCD. The address needs to be aligned to 32 bytes. |
| <i>nextStcd</i> | The pointer to the software TCD, which is to be linked to the software TCD. The address needs to be aligned to 32 bytes. |

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.7 static edma_status_t EDMA_DRV_PrepareDescriptorChannelLink (edma_software_tcd_t * *stcd*, uint32_t *linkChn*) [inline], [static]

If the major link is enabled, after the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel start bits.

Parameters

| | |
|----------------|--|
| <i>stcd</i> | The pointer to the software TCD. The address need to be aligned to 32 bytes. |
| <i>linkChn</i> | Channel number for major link |

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.8 static edma_status_t EDMA_DRV_PrepareDescriptorMinorLink (edma_software_tcd_t * *stcd*, uint32_t *linkChn*) [inline], [static]

If the minor link is enabled, after the minor loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel start bits.

Parameters

| | |
|----------------|--|
| <i>stcd</i> | The pointer to the software TCD. The address need to be aligned to 32 bytes. |
| <i>linkChn</i> | Channel number for minor link |

eDMA Peripheral driver

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.9 static edma_status_t EDMA_DRV_TriggerChannelStart (edma_chn_state_t * *chn*) [inline], [static]

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

kStatus_EDMA_Success.

17.3.12.10 edma_status_t EDMA_DRV_PushDescriptorToReg (edma_chn_state_t * *chn*, edma_software_tcd_t * *stcd*)

Parameters

| | |
|-------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
| <i>stcd</i> | memory pointing to the software TCD. |

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.11 edma_status_t EDMA_DRV_ConfigLoopTransfer (edma_chn_state_t * *chn*, edma_software_tcd_t * *stcd*, edma_transfer_type_t *type*, uint32_t *srcAddr*, uint32_t *destAddr*, uint32_t *size*, uint32_t *bytesOnEachRequest*, uint32_t *totalLength*, uint8_t *number*)

This function configures the descriptors in a loop chain. The user passes a block of memory into this function and the memory is divided into the "period" sub blocks. The DMA driver configures the "period" descriptors. Each descriptor stands for a sub block. The DMA driver transfers data from the first descriptor to the last descriptor. Then, the DMA driver wraps to the first descriptor to continue the loop. The interrupt handler is called every time a descriptor is completed. The user can get a transfer status of a descriptor by calling the edma_get_descriptor_status() function in the interrupt handler or any other task context.

At the same time, calling the `edma_update_descriptor()` function notifies the DMA driver that the content belonging to a descriptor is already updated and the DMA needs to count it as and underflow next time it loops to this descriptor. This is an example that describes how to use this interface in audio playback case:

1. Use a ping-pong buffer to transfer the data, the size of the each buffer is 1024 bytes.
2. Each DMA request needs to transfer 8 bytes.
3. The audio data is 16 bit.

```
edma_chn_state_t chn; <--- Simply allocates the structure.
edma_software_tcd_t stcd[2]; <--- Need 32 bytes aligned, two buffer block, needs 2 TCD.
uint32_t srcAddr = buffer; <-----Start address of the buffer.
uint32_t destAddr = SAI_TDR; <-----Destination address, usually SAI TDR register.

EDMA_DRV_ConfigLoopTransfer(&chn, stcd, kEDMAMemoryToPeripheral, srcAddr, destAddr,
kEDMATransferSize_2Bytes, 8, 2048, 2) ;
```

Parameters

| | |
|---------------------------|--|
| <i>chn</i> | The pointer to the channel state structure. |
| <i>stcd</i> | Memory pointing to software TCDs. The user must prepare this memory block. The required memory size is equal to a "period" * size of(<code>edma_software_tcd_t</code>). At the same time, the "stcd" must align with 32 bytes. If not, an error occurs in the eDMA driver. |
| <i>type</i> | Transfer type. |
| <i>srcAddr</i> | A source register address or a source memory address. |
| <i>destAddr</i> | A destination register address or a destination memory address. |
| <i>size</i> | Bytes to be transferred on every DMA write/read. Source/Dest share the same write/read size. |
| <i>bytesOnEachRequest</i> | Bytes to be transferred in each DMA request. |
| <i>totalLength</i> | Total bytes to be transferred in a loop cycle. In audio case, it means the total buffer size. |
| <i>number</i> | Number of TCDs, meaning how many parts the transfer data is divided into. For example, if the using ping-pong buffer for transfer, the number should be 2 and each buffer size is <code>totalLength/2</code> . |

Returns

An error code of `kStatus_EDMA_Success`

17.3.12.12 `edma_status_t EDMA_DRV_ConfigScatterGatherTransfer (edma_chn_state_t * chn, edma_software_tcd_t * stcd, edma_transfer_type_t type, uint32_t size, uint32_t bytesOnEachRequest, edma_scatter_gather_list_t * srcList, edma_scatter_gather_list_t * destList, uint8_t number)`

This function configures the descriptors into a single-ended chain. The user passes blocks of memory into this function. The interrupt is triggered only when the last memory block is completed. The memory

eDMA Peripheral driver

block information is passed with the [edma_scatter_gather_list_t](#) data structure, which can tell the memory address and length. The DMA driver configures the descriptor for each memory block, transfers the descriptor from the first one to the last one, and stops.

Parameters

| | |
|----------------------------|--|
| <i>chn</i> | The pointer to the channel state structure. |
| <i>stcd</i> | Memory pointing to software TCDs. The user must prepare this memory block. The required memory size is equal to the "number" * size of(edma_software_tcd_t). At the same time, the "stcd" must align with 32 bytes. If not, an error occurs in the eDMA driver. |
| <i>type</i> | Transfer type. |
| <i>size</i> | Bytes to be transferred on each DMA write/read. Source/Dest share the same write/read size. |
| <i>bytesOnEach-Request</i> | Bytes to be transferred in each DMA request. |
| <i>srcList</i> | Data structure storing the address and length to be transferred for source memory blocks. If the source memory is peripheral, the length is not used. |
| <i>destList</i> | Data structure storing the address and length to be transferred for destination memory blocks. If in the memory-to-memory transfer mode, the user must ensure that the length of the destination scatter gather list is equal to the source scatter gather list. If the destination memory is a peripheral register, the length is not used. |
| <i>number</i> | The number of TCD memory blocks contained in the scatter gather list. |

Returns

An error code of `kStatus_EDMA_Success`

17.3.12.13 edma_status_t EDMA_DRV_StartChannel (edma_chn_state_t * chn)

This function enables the eDMA channel DMA request.

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

An eDMA error codes or `kStatus_EDMA_Success`.

17.3.12.14 edma_status_t EDMA_DRV_StopChannel (edma_chn_state_t * *chn*)

This function disables the eDMA channel DMA request.

eDMA Peripheral driver

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.15 edma_status_t EDMA_DRV_InstallCallback (edma_chn_state_t * *chn*, edma_callback_t *callback*, void * *parameter*)

This function registers the callback function and the parameter into the eDMA channel state structure. The callback function is called when the channel is complete or a channel error occurs. The eDMA driver passes the channel status to this callback function to indicate whether it is caused by the channel complete event or the channel error event.

To un-register the callback function, set the callback function to "NULL" and call this function.

Parameters

| | |
|------------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
| <i>callback</i> | The pointer to the callback function. |
| <i>parameter</i> | The pointer to the callback function's parameter. |

Returns

An eDMA error codes or kStatus_EDMA_Success.

17.3.12.16 void EDMA_DRV_IRQHandler (uint8_t *channel*)

This function is provided as the default flow for eDMA channel interrupt. This function clears the status and calls the callback functions. The user can add this function into the hardware interrupt entry and implement a custom interrupt action function.

Parameters

| | |
|----------------|-------------------------|
| <i>channel</i> | Virtual channel number. |
|----------------|-------------------------|

17.3.12.17 void EDMA_DRV_ErrorIRQHandler (uint8_t *instance*)

This function is provided as the default action for eDMA module error interrupt. This function clears status, stops the error on a eDMA channel, and calls the eDMA channel callback function if the error eDMA channel is already requested. The user can add this function into the eDMA error interrupt entry and implement a custom interrupt action function.

Parameters

| | |
|-----------------|------------------------|
| <i>instance</i> | eDMA module indicator. |
|-----------------|------------------------|

17.3.12.18 static edma_chn_status_t EDMA_DRV_GetChannelStatus (edma_chn_state_t * *chn*) [inline], [static]

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

Channel status.

17.3.12.19 static uint32_t EDMA_DRV_GetUnfinishedBytes (edma_chn_state_t * *chn*) [inline], [static]

This function checks the TCD (Task Control Descriptor) status for a specified eDMA channel and returns the bytes that have not finished. This function can only be used for one TCD scenario.

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

Bytes already transferred for the current TCD.

eDMA Peripheral driver

17.3.12.20 `static uint32_t EDMA_DRV_GetFinishedBytes (edma_chn_state_t * chn)`
`[inline], [static]`

This function checks the TCD (Task Control Descriptor) status for a specified eDMA channel and returns the bytes that remain to the user. This function can only be used for one TCD scenario.

Parameters

| | |
|------------|---|
| <i>chn</i> | The pointer to the channel state structure. |
|------------|---|

Returns

Bytes already transferred for the current TCD.

17.3.13 Variable Documentation

17.3.13.1 **DMA_Type* const g_edmaBase[]**

17.3.13.2 **DMAMUX_Type* const g_dmamuxBase[]**

17.3.13.3 **const IRQn_Type g_edmaIrqld[DMA_INSTANCE_COUNT][FSL_FEATURE_EDMA_MODULE_CHANNEL]**

17.3.13.4 **const IRQn_Type g_edmaErrIrqld[DMA_INSTANCE_COUNT]**

eDMA request

17.4 eDMA request

17.4.1 Overview

This section describes the programming interface of the eDMA DMA request resource.

Enumerations

- enum [dma_request_source_t](#)
Structure for the DMA hardware request.
- enum [dma_request_source_t](#)
Structure for the DMA hardware request.

17.4.2 Enumeration Type Documentation

17.4.2.1 enum dma_request_source_t

Defines the structure for the DMA hardware request collections. The user can configure the hardware request into DMAMUX to trigger the DMA transfer accordingly. The index of the hardware request varies according to the to SoC.

17.4.2.2 enum dma_request_source_t

Defines the structure for the DMA hardware request collections. The user can configure the hardware request into DMAMUX to trigger the DMA transfer accordingly. The index of the hardware request varies according to the to SoC.

Chapter 18

Quadrature Encoder/Decoder (ENC)

18.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Quadrature Encoder/Decoder (ENC) block of Kinetis devices.

Modules

- [ENC HAL driver](#)
- [ENC Peripheral Driver](#)

ENC HAL driver

18.2 ENC HAL driver

18.2.1 Overview

The section describes the programming interface of the ENC HAL driver.

Enumerations

- enum `enc_status_t` {
`kStatus_ENC_Success` = 0U,
`kStatus_ENC_Error` = 1U,
`kStatus_ENC_InvalidArgument` = 2U }
Encoder status.
- enum `enc_operation_mode_t` {
`kEncNormalMode` = 0U,
`kEncModuloCountingMode` = 1U,
`kEncSignalPhaseCountMode` = 2U }
Encoder operation modes.
- enum `enc_status_flag_t` {
`kEncCmpFlag` = 0U,
`kEncHomeSignalFlag` = 1U,
`kEncWatchdogTimeoutFlag` = 2U,
`kEncIndexPulseFlag` = 3U,
`kEncRollunderFlag` = 4U,
`kEncRolloverFlag` = 5U,
`kEncSimultaneousFlag` = 6U,
`kEncCountDirectionFlag` = 7U }
Encoder status flags.
- enum `enc_int_source_t` {
`kEncIntCmp` = 0U,
`kEncIntHomeSignal` = 1U,
`kEncIntWatchdogTimeout` = 2U,
`kEncIntIndexPulse` = 3U,
`kEncIntRollunder` = 4U,
`kEncIntRollover` = 5U,
`kEncIntSimultaneous` = 6U }
Encoder interrupts.

Configuration

- void `ENC_HAL_Init` (ENC_Type *base)
Resets all configurable registers to be in the reset state for ENC.
- static void `ENC_HAL_SetCmpIntCmd` (ENC_Type *base, bool enable)
Switches to enable the Compare interrupt.
- static bool `ENC_HAL_GetCmpIntCmd` (ENC_Type *base)

- Gets the Compare Interrupt configuration setting.*

 - static bool [ENC_HAL_GetCmpIntFlag](#) (ENC_Type *base)
- Gets the Compare Interrupt Request configuration setting.*

 - static void [ENC_HAL_ClearCmpIntFlag](#) (ENC_Type *base)
- Clears the Compare Interrupt Request bit pending.*

 - static void [ENC_HAL_SetWatchdogCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Watchdog.*

 - static bool [ENC_HAL_GetWatchdogCmd](#) (ENC_Type *base)
- Gets the Watchdog configuration setting.*

 - static void [ENC_HAL_SetWatchdogIntCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Watchdog Timeout Interrupt.*

 - static bool [ENC_HAL_GetWatchdogIntCmd](#) (ENC_Type *base)
- Gets the Watchdog Timeout Interrupt configuration setting.*

 - static bool [ENC_HAL_GetWatchdogIntFlag](#) (ENC_Type *base)
- Gets the Watchdog Timeout Interrupt Request configuration setting.*

 - static void [ENC_HAL_ClearWatchdogIntFlag](#) (ENC_Type *base)
- Clears the Watchdog Timeout Interrupt Request pending.*

 - static void [ENC_HAL_SetIndexPulseNegativeEdgeCmd](#) (ENC_Type *base, bool enable)
- Sets the type of INDEX pulse edge.*

 - static bool [ENC_HAL_GetIndexPulseNegativeEdgeCmd](#) (ENC_Type *base)
- Gets INDEX pulse edge configuration setting.*

 - static void [ENC_HAL_SetIndexInitPosCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the INDEX to Initialize Position Counters UPOS and LPOS.*

 - static bool [ENC_HAL_GetIndexInitPosCmd](#) (ENC_Type *base)
- Gets the INDEX to Initialize Position Counters configuration setting.*

 - static void [ENC_HAL_SetIndexPulseIntCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the INDEX Pulse Interrupt.*

 - static bool [ENC_HAL_GetIndexPulseIntCmd](#) (ENC_Type *base)
- Gets the INDEX Pulse Interrupt configuration setting.*

 - static bool [ENC_HAL_GetIndexPulseIntFlag](#) (ENC_Type *base)
- Gets the INDEX Pulse Interrupt Request configuration setting.*

 - static void [ENC_HAL_ClearIndexPulseIntFlag](#) (ENC_Type *base)
- Clears the INDEX Pulse Interrupt Request pending.*

 - static void [ENC_HAL_SetSignalPhaseCountModeCmd](#) (ENC_Type *base, bool enable)
- Enables Signal Phase Count Mode.*

 - static bool [ENC_HAL_GetSignalPhaseCountModeCmd](#) (ENC_Type *base)
- Gets the Signal Phase Count Mode configuration setting.*

 - static void [ENC_HAL_SetReverseCountingCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Reverse Direction Counting.*

 - static bool [ENC_HAL_GetReverseCountingCmd](#) (ENC_Type *base)
- Gets Direction Counting configuration setting.*

 - static bool [ENC_HAL_GetLastCountDirectionFlag](#) (ENC_Type *base)
- Gets the Last Count Direction Flag.*

 - static void [ENC_HAL_InitPosCounter](#) (ENC_Type *base)
- Initializes the Position Counter.*

 - static void [ENC_HAL_SetHomeSignalNegativeEdgeCmd](#) (ENC_Type *base, bool enable)
- Sets the type of HOME Input Signal Edge.*

 - static bool [ENC_HAL_GetHomeSignalNegativeEdgeCmd](#) (ENC_Type *base)
- Gets HOME Input Signal Edge configuration setting.*

 - static void [ENC_HAL_SetHomeInitPosCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Initialize Position Counters UPOS and LPOS.*

ENC HAL driver

- static bool [ENC_HAL_GetHomeInitPosCmd](#) (ENC_Type *base)
Gets the HOME to Initialize Position Counters configuration setting.
- static void [ENC_HAL_SetHomeSignalIntCmd](#) (ENC_Type *base, bool enable)
Switches to enable the HOME Signal Interrupt.
- static bool [ENC_HAL_GetHomeSignalIntCmd](#) (ENC_Type *base)
Gets the HOME Signal Interrupt configuration setting.
- static bool [ENC_HAL_GetHomeSignalIntFlag](#) (ENC_Type *base)
Gets the HOME Signal Interrupt Request configuration setting.
- static void [ENC_HAL_ClearHomeSignalIntFlag](#) (ENC_Type *base)
Clears the HOME Signal Interrupt Request pending.
- static void [ENC_HAL_SetInputFilterSampleCount](#) (ENC_Type *base, uint8_t sampleCount)
Sets the Input Filter Sample Count.
- static uint8_t [ENC_HAL_GetInputFilterSampleCount](#) (ENC_Type *base)
Gets the Input Filter Sample Count.
- void [ENC_HAL_SetInputFilterSamplePeriod](#) (ENC_Type *base, uint8_t samplePeriod)
Sets the Input Filter Sample Period.
- static uint8_t [ENC_HAL_GetInputFilterSamplePeriod](#) (ENC_Type *base)
Gets the Input Filter Sample Period.
- static void [ENC_HAL_SetWatchdogTimeout](#) (ENC_Type *base, uint16_t wdtTimeout)
Sets the Watchdog timeout register.
- static uint16_t [ENC_HAL_GetWatchdogTimeout](#) (ENC_Type *base)
Gets the Watchdog timeout register.
- static void [ENC_HAL_SetPosDiffCounterReg](#) (ENC_Type *base, uint16_t diffPosition)
Sets the Position Difference Counter Register.
- static uint16_t [ENC_HAL_GetPosDiffCounterReg](#) (ENC_Type *base)
Gets the Position Difference Counter Register.
- static uint16_t [ENC_HAL_GetPosDiffHoldReg](#) (ENC_Type *base)
Gets the Position Difference Hold Register.
- static void [ENC_HAL_SetRevolutionCounterReg](#) (ENC_Type *base, uint16_t revValue)
Sets the Revolution Counter Register.
- static uint16_t [ENC_HAL_GetRevolutionCounterReg](#) (ENC_Type *base)
Gets the Revolution Counter Register.
- static uint16_t [ENC_HAL_GetRevolutionHoldReg](#) (ENC_Type *base)
Gets the Revolution Hold Register.
- uint32_t [ENC_HAL_GetPosCounterReg](#) (ENC_Type *base)
Gets the Position Counter Register.
- void [ENC_HAL_SetPosCounterReg](#) (ENC_Type *base, uint32_t posVal)
Sets the Position Counter Register.
- uint32_t [ENC_HAL_GetPosHoldReg](#) (ENC_Type *base)
Gets the Position Hold Register.
- void [ENC_HAL_SetInitReg](#) (ENC_Type *base, uint32_t initValue)
Sets the Initialization Register.
- uint32_t [ENC_HAL_GetInitReg](#) (ENC_Type *base)
Gets the Initialization Register.
- static bool [ENC_HAL_GetRawHomeInput](#) (ENC_Type *base)
Gets the Raw HOME Input.
- static bool [ENC_HAL_GetRawIndexInput](#) (ENC_Type *base)
Gets the Raw INDEX Input.
- static bool [ENC_HAL_GetRawPhaseBInput](#) (ENC_Type *base)
Gets the Raw PHASEB Input.
- static bool [ENC_HAL_GetRawPhaseAInput](#) (ENC_Type *base)

- Gets the Raw PHASEA Input.*

 - static bool [ENC_HAL_GetFilteredHomeInput](#) (ENC_Type *base)
- Gets the Filtered HOME Input.*

 - static bool [ENC_HAL_GetFilteredIndexInput](#) (ENC_Type *base)
- Gets the Filtered INDEX Input.*

 - static bool [ENC_HAL_GetFilteredPhaseBInput](#) (ENC_Type *base)
- Gets the Filtered PHASEB Input.*

 - static bool [ENC_HAL_GetFilteredPhaseAInput](#) (ENC_Type *base)
- Gets the Filtered PHASEA Input.*

 - static uint8_t [ENC_HAL_GetTestCount](#) (ENC_Type *base)
- Gets the ENC Test Count.*

 - static void [ENC_HAL_SetTestCount](#) (ENC_Type *base, uint8_t testCount)
- Sets the ENC Test Count.*

 - static uint8_t [ENC_HAL_GetTestPeriod](#) (ENC_Type *base)
- Gets the ENC Test Period.*

 - static void [ENC_HAL_SetTestPeriod](#) (ENC_Type *base, uint8_t testPeriod)
- Sets the ENC Test Period.*

 - static void [ENC_HAL_SetNegativeTestSignalCmd](#) (ENC_Type *base, bool enable)
- Sets the Quadrature Decoder Test Signal.*

 - static bool [ENC_HAL_GetNegativeTestSignalCmd](#) (ENC_Type *base)
- Gets the Quadrature Decoder Test Signal configuration setting.*

 - static void [ENC_HAL_SetTestCounterCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Test Counter.*

 - static bool [ENC_HAL_GetTestCounterCmd](#) (ENC_Type *base)
- Tests the Test Counter Enable bit.*

 - static void [ENC_HAL_SetTestModuleCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Test Module.*

 - static bool [ENC_HAL_GetTestModuleCmd](#) (ENC_Type *base)
- Tests the Test Module Enable bit.*

 - void [ENC_HAL_SetModulusReg](#) (ENC_Type *base, uint32_t modValue)
- Sets the ENC Modulus Register.*

 - uint32_t [ENC_HAL_GetModulusReg](#) (ENC_Type *base)
- Gets the ENC Modulus Register.*

 - void [ENC_HAL_SetCmpReg](#) (ENC_Type *base, uint32_t cmpValue)
- Sets the ENC Compare Register.*

 - uint32_t [ENC_HAL_GetCmpReg](#) (ENC_Type *base)
- Gets the ENC Compare Register.*

 - static void [ENC_HAL_SetTriggerUpdateHoldRegCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Update Hold Registers.*

 - static bool [ENC_HAL_GetTriggerUpdateHoldRegCmd](#) (ENC_Type *base)
- Gets the Update Hold Registers configuration setting.*

 - static void [ENC_HAL_SetTriggerClearPosRegCmd](#) (ENC_Type *base, bool enable)
- Enables Update Position Registers.*

 - static bool [ENC_HAL_GetTriggerClearPosRegCmd](#) (ENC_Type *base)
- Gets the Update Position Registers configuration setting.*

 - static void [ENC_HAL_SetModuloCountingCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Modulo Counting.*

 - static bool [ENC_HAL_GetModuloCountingCmd](#) (ENC_Type *base)
- Gets the Modulo Counting configuration setting.*

 - static void [ENC_HAL_SetRollunderIntCmd](#) (ENC_Type *base, bool enable)
- Switches to enable the Roll-under Interrupt.*

ENC HAL driver

- static bool [ENC_HAL_GetRollunderIntCmd](#) (ENC_Type *base)
Gets the Roll-under Interrupt configuration setting.
- static bool [ENC_HAL_GetRollunderIntFlag](#) (ENC_Type *base)
Gets the Roll-under Interrupt Request configuration setting.
- static void [ENC_HAL_ClearRollunderIntFlag](#) (ENC_Type *base)
Clears the Roll-under Interrupt Request pending.
- static void [ENC_HAL_SetRolloverIntCmd](#) (ENC_Type *base, bool enable)
Switches to enable the Roll-over Interrupt.
- static bool [ENC_HAL_GetRolloverIntCmd](#) (ENC_Type *base)
Gets the Roll-over Interrupt configuration setting.
- static bool [ENC_HAL_GetRolloverIntFlag](#) (ENC_Type *base)
Gets the Roll-over Interrupt Request configuration setting.
- static void [ENC_HAL_ClearRolloverIntFlag](#) (ENC_Type *base)
Clears the Roll-over Interrupt Request pending.
- static void [ENC_HAL_SetModulusRevCounterCmd](#) (ENC_Type *base, bool enable)
Switches to enable the Modulus Revolution Counter.
- static bool [ENC_HAL_GetModulusRevCounterCmd](#) (ENC_Type *base)
Gets the Modulus Revolution Counter configuration setting.
- static void [ENC_HAL_SetPosmatchOnReadingCmd](#) (ENC_Type *base, bool enable)
Switches to enable the POSMATCH to pulse on Counters registers reading.
- static bool [ENC_HAL_GetPosmatchOnReadingCmd](#) (ENC_Type *base)
Gets the POSMATCH Output configuration setting.
- static void [ENC_HAL_SetSimultaneousIntCmd](#) (ENC_Type *base, bool enable)
Switches to enable the Simultaneous PHASEA and PHASEB Change Interrupt.
- static bool [ENC_HAL_GetSimultaneousIntCmd](#) (ENC_Type *base)
Gets the SAB Interrupt configuration setting.
- static bool [ENC_HAL_GetSimultaneousIntFlag](#) (ENC_Type *base)
Gets the SAB Interrupt Request configuration setting.
- static void [ENC_HAL_ClearSimultaneousIntFlag](#) (ENC_Type *base)
Clears the SAB Interrupt Request pending.

18.2.2 Enumeration Type Documentation

18.2.2.1 enum enc_status_t

Enumerator

- kStatus_ENC_Success* Encoder success status.
- kStatus_ENC_Error* Encoder error status.
- kStatus_ENC_InvalidArgument* Encoder invalid argument.

18.2.2.2 enum enc_operation_mode_t

Enumerator

- kEncNormalMode* Normal mode (transition signal counting).
- kEncModuloCountingMode* Modulo counting mode.
- kEncSignalPhaseCountMode* Signal phase count mode (pulse counting).

18.2.2.3 enum enc_status_flag_t

Enumerator

- kEncCmpFlag* Encoder Compare status flag.
- kEncHomeSignalFlag* Encoder HOME Signal transition status flag.
- kEncWatchdogTimeoutFlag* Encoder Watchdog timeout status flag.
- kEncIndexPulseFlag* Encoder INDEX Pulse transition status flag.
- kEncRollunderFlag* Encoder Roll-under status flag.
- kEncRolloverFlag* Encoder Roll-over status flag.
- kEncSimultaneousFlag* Encoder Simultaneous PHA and PHB change status flag.
- kEncCountDirectionFlag* Encoder Last count direction status flag.

18.2.2.4 enum enc_int_source_t

Enumerator

- kEncIntCmp* Compare interrupt source.
- kEncIntHomeSignal* HOME signal interrupt source.
- kEncIntWatchdogTimeout* Watchdog timeout interrupt source.
- kEncIntIndexPulse* INDEX pulse interrupt source.
- kEncIntRollunder* Roll-under position counter interrupt source.
- kEncIntRollover* Roll-over position counter interrupt source.
- kEncIntSimultaneous* Simultaneous PHASEA and PHASEB change interrupt source.

18.2.3 Function Documentation

18.2.3.1 void ENC_HAL_Init (ENC_Type * base)

This function resets all configurable registers to be in the reset state for ENC. It should be called before configuring the ENC module.

Parameters

| | |
|-------------|----------------------------------|
| <i>base</i> | The ENC peripheral base address. |
|-------------|----------------------------------|

18.2.3.2 static void ENC_HAL_SetCmplntCmd (ENC_Type * base, bool enable) [inline], [static]

This function allows the user to enable/disable compare interrupt.

ENC HAL driver

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.3 static bool ENC_HAL_GetCmplntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the compare interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of compare interrupt setting.

18.2.3.4 static bool ENC_HAL_GetCmplntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the compare interrupt request. This bit is set when a match occurs between the counter and the COMP value. It will remain set until cleared by software.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the compare interrupt request bit.

18.2.3.5 static void ENC_HAL_ClearCmplntFlag (ENC_Type * *base*) [inline], [static]

This function clears the compare interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

**18.2.3.6 static void ENC_HAL_SetWatchdogCmd (ENC_Type * *base*, bool *enable*)
[inline], [static]**

This function allows the user to enable watchdog timer. Allow operation of the watchdog timer monitoring the PHESEA and PHASEB inputs for motor movement.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

**18.2.3.7 static bool ENC_HAL_GetWatchdogCmd (ENC_Type * *base*) [inline],
[static]**

This function allows the user to get the watchdog configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of watchdog.

**18.2.3.8 static void ENC_HAL_SetWatchdogIntCmd (ENC_Type * *base*, bool *enable*)
[inline], [static]**

This function allows the user to enable watchdog timeout interrupt.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

ENC HAL driver

| | |
|---------------|-----------------------------------|
| <i>enable</i> | Bool parameter to enable/disable. |
|---------------|-----------------------------------|

18.2.3.9 static bool ENC_HAL_GetWatchdogIntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the watchdog timeout interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of wdt timeout interrupt setting.

18.2.3.10 static bool ENC_HAL_GetWatchdogIntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the watchdog timeout interrupt request. This bit is set when a watchdog timeout interrupt occurs. It will remain set until cleared by software. This bit is also cleared when watchdog is disabled.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the wdt timeout interrupt request bit.

18.2.3.11 static void ENC_HAL_ClearWatchdogIntFlag (ENC_Type * *base*) [inline], [static]

This function clears the watchdog timeout interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.12 static void ENC_HAL_SetIndexPulseNegativeEdgeCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to set the type of INDEX pulse edge used to initialize the position counter.

Parameters

| | |
|---------------|-------------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | The edge type of INDEX pulse input. |

18.2.3.13 static bool ENC_HAL_GetIndexPulseNegativeEdgeCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the type of INDEX pulse edge.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The INDEX pulse edge configuration setting

18.2.3.14 static void ENC_HAL_SetIndexInitPosCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable INDEX pulse to initialize position counters UPOS and LPOS.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.15 static bool ENC_HAL_GetIndexInitPosCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the INDEX to initialize position counters configuration setting.

ENC HAL driver

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of INDEX init position counters.

18.2.3.16 static void ENC_HAL_SetIndexPulseIntCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the INDEX pulse interrupt.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.17 static bool ENC_HAL_GetIndexPulseIntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the INDEX pulse interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of INDEX pulse interrupt setting.

18.2.3.18 static bool ENC_HAL_GetIndexPulseIntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the INDEX pulse interrupt request. This bit is set when an INDEX interrupt occurs. It will remain set until cleared by software.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the INDEX pulse interrupt request bit.

18.2.3.19 static void ENC_HAL_ClearIndexPulseIntFlag (ENC_Type * *base*) [inline], [static]

This function clears the INDEX pulse interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.20 static void ENC_HAL_SetSignalPhaseCountModeCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the signal phase count mode which bypasses the quadrature decoder. A positive transition of the PHASEA input generates a count signal. The PHASEB input and the REV (direction control bit) control the counter direction.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.21 static bool ENC_HAL_GetSignalPhaseCountModeCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the signal phase counter mode configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

ENC HAL driver

Returns

The state of signal phase count mode setting.

18.2.3.22 static void ENC_HAL_SetReverseCountingCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the reverse direction counting. It reverses the interpretation of the quadrature signal, changing the direction of count.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.23 static bool ENC_HAL_GetReverseCountingCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the counting type configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The count type configuration setting.

18.2.3.24 static bool ENC_HAL_GetLastCountDirectionFlag (ENC_Type * *base*) [inline], [static]

This function allows the user to get the flag that indicates the direction of the last count. Returns true if last count was in the up direction or returns false if last count was in the down direction.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of count direction.

18.2.3.25 static void ENC_HAL_InitPosCounter (ENC_Type * *base*) [inline], [static]

This function allows the user to initialize position counters UPOS and LPOS. It will transfer the UINIT and LINIT contents to UPOS and LPOS.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.26 static void ENC_HAL_SetHomeSignalNegativeEdgeCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to set the type of HOME input signal edge. Use positive or negative going edge-to-trigger initialization of position counters UPOS and LPOS.

Parameters

| | |
|---------------|-------------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | The edge type of HOME input signal. |

18.2.3.27 static bool ENC_HAL_GetHomeSignalNegativeEdgeCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the HOME input signal edge configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The edge type of HOME input signal.

ENC HAL driver

18.2.3.28 `static void ENC_HAL_SetHomeInitPosCmd (ENC_Type * base, bool enable)`
`[inline], [static]`

This function allows the user to enable HOME signal to initialize position counters UPOS and LPOS.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.29 static bool ENC_HAL_GetHomeInitPosCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the HOME signal input init configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of HOME signal initialization POS counters.

18.2.3.30 static void ENC_HAL_SetHomeSignalIntCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the HOME signal interrupt.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.31 static bool ENC_HAL_GetHomeSignalIntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the HOME signal interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

ENC HAL driver

Returns

The state of HOME signal interrupt setting.

18.2.3.32 static bool ENC_HAL_GetHomeSignalIntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the HOME signal interrupt request. This bit is set when a transition on the HOME signal occurs. It will remain set until it is cleared by software.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the HOME signal interrupt request bit.

18.2.3.33 static void ENC_HAL_ClearHomeSignalIntFlag (ENC_Type * *base*) [inline], [static]

This function clears the HOME signal interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.34 static void ENC_HAL_SetInputFilterSampleCount (ENC_Type * *base*, uint8_t *sampleCount*) [inline], [static]

This function allows the user to set the input filter sample counts. The value represents the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0x0 represents 3 samples. A value of 0x7 represents 10 samples. A value of *sampleCount* affects the input latency.

Parameters

| | |
|--------------------|--|
| <i>base</i> | The ENC module base address. |
| <i>sampleCount</i> | Value that represents the number of consecutive samples. |

**18.2.3.35 static uint8_t ENC_HAL_GetInputFilterSampleCount (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the input filter sample counts. The value represents the number of consecutive samples that must agree prior to the input filter accepting an input transition.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value that represents the number of consecutive samples.

**18.2.3.36 void ENC_HAL_SetInputFilterSamplePeriod (ENC_Type * *base*, uint8_t
samplePeriod)**

This function allows the user to set the input filter sample period. This value represents the sampling period of the decoder input signals. Each input is sampled multiple times at the rate specified by this field. If *samplePeriod* is 0x00 (default), then the input filter is bypassed. Bypassing the digital filter enables the position/position difference counters to operate with count rates up to the IPBus frequency. The value of *samplePeriod* affects the input latency.

Parameters

| | |
|---------------------|--------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>samplePeriod</i> | Value of filter sample period. |

**18.2.3.37 static uint8_t ENC_HAL_GetInputFilterSamplePeriod (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the input filter sample period. This value represents the sampling period of the decoder input signals.

ENC HAL driver

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of filter sample period.

18.2.3.38 **static void ENC_HAL_SetWatchdogTimeout (ENC_Type * *base*, uint16_t *wdtTimeout*) [inline], [static]**

This function allows the user to set the timeout value for Watchdog timer, which is separated from the watchdog timer in the COP module. Timeout value is the number of clock cycles plus one that the watchdog timer counts before timing out and optionally generating an interrupt.

Parameters

| | |
|-------------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>wdtTimeout</i> | Value of watchdog timeout. |

18.2.3.39 **static uint16_t ENC_HAL_GetWatchdogTimeout (ENC_Type * *base*) [inline], [static]**

This function allows the user to read the timeout value for Watchdog timer, which is separated from the watchdog timer in the COP module. Timeout value is the number of clock cycles plus one that the watchdog timer counts before timing out and optionally generating an interrupt.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of watchdog timeout.

18.2.3.40 **static void ENC_HAL_SetPosDiffCounterReg (ENC_Type * *base*, uint16_t *diffPosition*) [inline], [static]**

This function allows the user to write the POSD register. It contains the position change in value occurring between each read of the position register. The value of the position difference counter register can be used to calculate velocity.

Parameters

| | |
|---------------------|-------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>diffPosition</i> | Value of position difference. |

**18.2.3.41 static uint16_t ENC_HAL_GetPosDiffCounterReg (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the POSD register. It contains the position change in value occurring between each read of the position register. The value of the position difference counter register can be used to calculate velocity. The 16-bit position difference counter computes up or down on every count pulse. This counter acts as a differentiator whose count value is proportional to the change in position since the last time the position counter was read. When the position register, the position difference counter, or the revolution counter is read, the position difference counter's contents are copied into the position difference hold register (POSDH) and the position difference counter is cleared.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of position difference hold register.

**18.2.3.42 static uint16_t ENC_HAL_GetPosDiffHoldReg (ENC_Type * *base*) [inline],
[static]**

This function allows the user to read the POSD Hold register. Hold register contains a snapshot of the value of the position difference register. The value of the position difference hold register can be used to calculate velocity.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of position difference hold register.

**18.2.3.43 static void ENC_HAL_SetRevolutionCounterReg (ENC_Type * *base*, uint16_t
revValue) [inline], [static]**

This function allows the user to write the Revolution counter.

ENC HAL driver

Parameters

| | |
|-----------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>revValue</i> | Value of revolution. |

**18.2.3.44 static uint16_t ENC_HAL_GetRevolutionCounterReg (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the Revolution counter.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of revolution counter.

**18.2.3.45 static uint16_t ENC_HAL_GetRevolutionHoldReg (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the Revolution Hold register. Contains a snapshot of the value of the revolution counter register.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of revolution hold register.

18.2.3.46 uint32_t ENC_HAL_GetPosCounterReg (ENC_Type * *base*)

This function allows the user to read the Position counter.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of position counter.

18.2.3.47 void ENC_HAL_SetPosCounterReg (ENC_Type * *base*, uint32_t *posVal*)

This function allows the user to write the Position counter.

Parameters

| | |
|---------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>posVal</i> | Value of position counter. |

18.2.3.48 uint32_t ENC_HAL_GetPosHoldReg (ENC_Type * *base*)

This function allows the user to read the Position hold register. Contains a snapshot of the position counter register.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of position hold register.

18.2.3.49 void ENC_HAL_SetInitReg (ENC_Type * *base*, uint32_t *initValue*)

This function allows the user to write the initialization register.

Parameters

| | |
|------------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>initValue</i> | Value of initialization register. |

ENC HAL driver

18.2.3.50 `uint32_t ENC_HAL_GetInitReg (ENC_Type * base)`

This function allows the user to read the initialization register.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of initialization register.

18.2.3.51 `static bool ENC_HAL_GetRawHomeInput (ENC_Type * base) [inline], [static]`

This function allows the user to read the value of the raw HOME input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the raw HOME input.

18.2.3.52 `static bool ENC_HAL_GetRawIndexInput (ENC_Type * base) [inline], [static]`

This function allows the user to read the value of the raw INDEX input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the raw INDEX input.

18.2.3.53 `static bool ENC_HAL_GetRawPhaseBInput (ENC_Type * base) [inline], [static]`

This function allows the user to read the value of the raw PHASEB input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the raw PHASEB input.

18.2.3.54 static bool ENC_HAL_GetRawPhaseAInput (ENC_Type * *base*) [inline], [static]

This function allows the user to read the value of the raw PHASEA input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the raw PHASEA input.

18.2.3.55 static bool ENC_HAL_GetFilteredHomeInput (ENC_Type * *base*) [inline], [static]

This function allows the user to read the value of the filtered HOME input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the filtered HOME input.

18.2.3.56 static bool ENC_HAL_GetFilteredIndexInput (ENC_Type * *base*) [inline], [static]

This function allows the user to read the value of the filtered INDEX input.

ENC HAL driver

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the filtered INDEX input.

**18.2.3.57 static bool ENC_HAL_GetFilteredPhaseBInput (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the value of the filtered PHASEB input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the filtered PHASEB input.

**18.2.3.58 static bool ENC_HAL_GetFilteredPhaseAInput (ENC_Type * *base*)
[inline], [static]**

This function allows the user to read the value of the filtered PHASEA input.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of the filtered PHASEA input.

**18.2.3.59 static uint8_t ENC_HAL_GetTestCount (ENC_Type * *base*) [inline],
[static]**

This function allows the user to read the test count value of the test register. This value holds the number of quadrature advances to generate.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of test count.

18.2.3.60 static void ENC_HAL_SetTestCount (ENC_Type * *base*, uint8_t *testCount*) [inline], [static]

This function allows the user to write the test count value of the test register. This value holds the number of quadrature advances to generate.

Parameters

| | |
|------------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>testCount</i> | Value of test count. |

18.2.3.61 static uint8_t ENC_HAL_GetTestPeriod (ENC_Type * *base*) [inline], [static]

This function allows the user to read the test period value of the test register. This value holds the period of quadrature phase in IPBus clock cycles.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of test period.

18.2.3.62 static void ENC_HAL_SetTestPeriod (ENC_Type * *base*, uint8_t *testPeriod*) [inline], [static]

This function allows the user to write the test period value of the test register. This value holds the period of quadrature phase in IPBus clock cycles.

ENC HAL driver

Parameters

| | |
|-------------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>testPeriod</i> | Value of test period. |

18.2.3.63 **static void ENC_HAL_SetNegativeTestSignalCmd (ENC_Type * *base*, bool *enable*) [inline], [static]**

This function allows the user to set the quadrature decoder test signal. Test module can generate quadrature decoder signal in a positive or negative direction.

Parameters

| | |
|---------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | The type of test signal. |

18.2.3.64 **static bool ENC_HAL_GetNegativeTestSignalCmd (ENC_Type * *base*) [inline], [static]**

This function allows the user to get the test signal configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The type of test signal.

18.2.3.65 **static void ENC_HAL_SetTestCounterCmd (ENC_Type * *base*, bool *enable*) [inline], [static]**

This function allows the user to enable test counter. It connects the test counter to inputs of the quadrature decoder module.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.66 static bool ENC_HAL_GetTestCounterCmd (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the test counter enable bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the test counter enable.

18.2.3.67 static void ENC_HAL_SetTestModuleCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable test module. Connects the test module to inputs of the quadrature decoder module.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.68 static bool ENC_HAL_GetTestModuleCmd (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the test module enable bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the test module enable.

ENC HAL driver

18.2.3.69 void ENC_HAL_SetModulusReg (ENC_Type * *base*, uint32_t *modValue*)

This function allows the user to write the ENC modulus register. Modulus acts as the upper bound during modulo counting and as the upper reload value when rolling over from the lower bound.

Parameters

| | |
|-----------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>modValue</i> | Value of modulo register. |

18.2.3.70 `uint32_t ENC_HAL_GetModulusReg (ENC_Type * base)`

This function allows the user to read the ENC modulus register. Modulus acts as the upper bound during modulo counting and as the upper reload value when rolling over from the lower bound.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of modulo register.

18.2.3.71 `void ENC_HAL_SetCmpReg (ENC_Type * base, uint32_t cmpValue)`

This function allows the user to write the ENC compare register. When the value of Position counter matches the value of Compare register the CTRL[CMPIRQ] flag is set and the POSMATCH output is asserted.

Parameters

| | |
|-----------------|------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>cmpValue</i> | Value of modulo register. |

18.2.3.72 `uint32_t ENC_HAL_GetCmpReg (ENC_Type * base)`

This function allows the user to read the ENC compare register. When the value of Position counter matches the value of Compare register the CTRL[CMPIRQ] flag is set and the POSMATCH output is asserted.

Parameters

ENC HAL driver

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Value of modulo register.

18.2.3.73 **static void ENC_HAL_SetTriggerUpdateHoldRegCmd (ENC_Type * *base*, bool *enable*) [inline], [static]**

This function allows the user to enable the update hold registers on external trigger input. Updating POS-DH register will also cause the POSD register to be cleared.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.74 **static bool ENC_HAL_GetTriggerUpdateHoldRegCmd (ENC_Type * *base*) [inline], [static]**

This function allows the user to get the update hold registers configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of update hold registers

18.2.3.75 **static void ENC_HAL_SetTriggerClearPosRegCmd (ENC_Type * *base*, bool *enable*) [inline], [static]**

This function allows the user to enable the update of position registers on external trigger input. Allows the TRIGGER input to clear POSD, REV, UPOS and LPOS registers on rising edge.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

**18.2.3.76 static bool ENC_HAL_GetTriggerClearPosRegCmd (ENC_Type * *base*)
[inline], [static]**

This function allows the user to get the update of position registers configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of update position registers

**18.2.3.77 static void ENC_HAL_SetModuloCountingCmd (ENC_Type * *base*, bool *enable*)
[inline], [static]**

This function allows the user to enable the modulo counting. It allows the position counters to count in a modulo fashion using MOD and INIT as the upper and lower bounds of the counting range.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

**18.2.3.78 static bool ENC_HAL_GetModuloCountingCmd (ENC_Type * *base*)
[inline], [static]**

This function allows the user to get the modulo counting configuration setting.

Parameters

ENC HAL driver

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of modulo counting.

18.2.3.79 static void ENC_HAL_SetRollunderIntCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the roll-under interrupt.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.80 static bool ENC_HAL_GetRollunderIntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the roll-under interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of roll-under interrupt setting.

18.2.3.81 static bool ENC_HAL_GetRollunderIntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the Roll-under interrupt request. It is set when the position counter rolls under from the INIT value to the MOD value or from 0x00000000 to 0xFFFFFFFF. It will remain set until cleared by software.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the interrupt request bit.

18.2.3.82 static void ENC_HAL_ClearRollunderIntFlag (ENC_Type * *base*) [inline], [static]

This function clears the roll-under interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.83 static void ENC_HAL_SetRolloverIntCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the roll-over interrupt.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.84 static bool ENC_HAL_GetRolloverIntCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the roll-over interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of roll-over interrupt setting.

ENC HAL driver

18.2.3.85 static bool ENC_HAL_GetRolloverIntFlag (ENC_Type * *base*) [inline], [static]

This function returns the configuration setting of the Roll-over interrupt request. It is set when the position counter rolls over the MOD value to the INIT value or from 0xFFFFFFFF to 0x00000000. It will remain set until cleared by software.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the interrupt request bit.

18.2.3.86 static void ENC_HAL_ClearRolloverIntFlag (ENC_Type * *base*) [inline], [static]

This function clears the roll-over interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

18.2.3.87 static void ENC_HAL_SetModulusRevCounterCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the modulo revolution counter. This is used to determine how the revolution counter (REV) is incremented or decremented. By default REV is controlled based on the count direction and the INDEX pulse. As an option, REV can be controlled using the roll-over/under detection during modulo counting.

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.88 static bool ENC_HAL_GetModulusRevCounterCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the modulus revolution counter configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of modulus revolution counter.

18.2.3.89 static void ENC_HAL_SetPosmatchOnReadingCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to config control of the POSMATCH output. POSMATCH pulses when the UPOS, LPOS, REV or POSD registers are read - when set true or when match occurred between position register and Compare value register (false).

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.90 static bool ENC_HAL_GetPosmatchOnReadingCmd (ENC_Type * *base*) [inline], [static]

This function allows the user to get the POSMATCH output configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of POSMATCH output setting.

18.2.3.91 static void ENC_HAL_SetSimultaneousIntCmd (ENC_Type * *base*, bool *enable*) [inline], [static]

This function allows the user to enable the SAB interrupt.

ENC HAL driver

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENC module base address. |
| <i>enable</i> | Bool parameter to enable/disable. |

18.2.3.92 **static bool ENC_HAL_GetSimultaneousIntCmd (ENC_Type * *base*)** **[inline], [static]**

This function allows the user to get the SAB interrupt configuration setting.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

The state of SAB interrupt setting.

18.2.3.93 **static bool ENC_HAL_GetSimultaneousIntFlag (ENC_Type * *base*)** **[inline], [static]**

This function returns the configuration setting of the SAB interrupt request. It indicates that the PHASEA and PHASEB inputs changed simultaneously (within a single clock period). This event typically indicates an error condition because quadrature coding requires only one of these inputs to change at a time. The bit remains set until it is cleared by software or a reset.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

Returns

Bit setting of the interrupt request bit.

18.2.3.94 **static void ENC_HAL_ClearSimultaneousIntFlag (ENC_Type * *base*)** **[inline], [static]**

This function clears the SAB interrupt request bit.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | The ENC module base address. |
|-------------|------------------------------|

ENC Peripheral Driver

18.3 ENC Peripheral Driver

18.3.1 Overview

The section describes the programming interface of the ENC Peripheral driver.

18.3.2 Overview

The enhanced Quadrature Encoder/Decoder module provides interfacing capability to position/speed sensors used in industrial motor control applications. It has four input signals: PHASEA, PHASEB, INDEX, and HOME. This module is used to decode shaft position, revolution count, and speed.

18.3.3 Initialization

To initialize the ENC module, call the [ENC_DRV_Init\(\)](#) function and pass the configuration data structure ([enc_user_config_t](#)), which can be filled by the [ENC_DRV_StructInitUserConfigNormal\(\)](#) function with the default settings for the encoder. After it is initialized, the ENC module can function as an ENC decoder. The default settings are as follows.

```
enc_state_t encUserState;
enc_user_config_t encUserConfig;

encUserConfig.operationMode = kEncNormalMode;      /* Operation mode: Normal
mode, modulo counting mode or bypass (signal phase count) mode.
encUserConfig.reverseCounting = false;            /* Counting direction: Normal (false) or reverse (true)
counting direction.
encUserConfig.indexInputNegativeEdge = false;     /* Type of transition edge of INDEX input signal:
positive (false) or negative (true).
encUserConfig.homeInputNegativeEdge = false;     /* Type of transition edge of HOME input signal:
positive (false) or negative (true).
encUserConfig.indexPulsePosInit = true;          /* To use HOME (false) or INDEX (true) input to
initialize position counter to value in Initialization Register.
encUserConfig.posCntInitValue = 0;               /* Value to put in Initialization Register.
encUserConfig.posCmpValue = 0xFFFF;            /* Value to put in Position Compare Register.
encUserConfig.moduloValue = 0;                 /* Value to put in Modulus Register.
encUserConfig.triggerUpdateHoldRegEnable = false; /* Enable/disable updating hold registers on TRIGGER
input.
encUserConfig.triggerClearPosRegEnable = false; /* Enable/disable clear of position registers on
TRIGGER input.
encUserConfig.moduloRevolutionCounting = false; /* Type of revolution counter - index pulse counting
(on false) or modulo counting (on true).
encUserConfig.outputControlOnReading = false;    /* Used to control the behaviour of the POSMATCH output
signal. True - output control on reading position register, false - OC on match position register.
encUserConfig.watchdogTimeout = 0;             /* Value to put in Watchdog Timeout Register.
encUserConfig.filterCount = 0;                 /* Value represents the number of consecutive samples
that must agree prior to the input filter accepting an input transition.
encUserConfig.filterPeriod = 0;                /* Value represents the sampling period (in IPBus clock
cycles) of the decoder input signals.
```

Ensure that any default settings are changed after calling the [ENC_DRV_StructInitUserConfigNormal\(\)](#) function. For example, changing INDEX input edge type and position compare register value:

```
encUserConfig.indexPulsePosInit = true;
encUserConfig.posCmpValue = 0x1010;
```

After that, the initialization is completed by calling the initialization function:

```
ENC_DRV_Init(instance, &encUserConfig, &encUserState);
```

To de-initialize the ENC peripheral, call the `ENC_DRV_Deinit()` function which shuts down the ENC clock to reduce the power consumption.

18.3.4 Testing ENC module

The ENC peripheral provides a test module to drive the ENC quadrature inputs which can provide a mechanism for customers to test the ENC module is functioning without being connected in the intended "incremental position sensor" for motor control.

To initialize the ENC Test module, call the `ENC_DRV_TestInit()` function and pass the configuration data structure (`enc_test_config_t`), which can be filled as the example shows.

```
enc_test_config_t encTestConfig;

encTestConfig.testNegativeSignalEnable = false;
encTestConfig.testCount = 100;
encTestConfig.testPeriod = 10;

ENC_DRV_TestInit(instance, &encTestConfig);
```

Test module generates 100 quadrature advances into quadrature inputs with period 10 IPBus clock cycles.

18.3.5 Input monitor

ENC peripheral also provides monitoring of input signals. It can be used as follows.

```
enc_input_monitor_t encInputMonitor;

ENC_DRV_ReadInputMonitorRegister(instance, true, &encInputMonitor);
```

The `encInputMonitor` structure contains the values of the raw (if true) or filtered (if false) PHASEA, PHASEB, INDEX and HOME input signals and the reset value of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME. If the input pins are connected to a pull-up, IMR 0-7 bits are set to one (1). If these input pins are connected to a pull-down device, the 0-7 bits are set to zeroes (0).

18.3.6 Interrupts

Interrupt may be enabled/disabled by calling the `ENC_DRV_SetIntMode()` function and passing the interrupt source `enc_interrupt_source_t` argument. The user callback function can be installed by calling the `ENC_DRV_InstallCallback()` function and passing the name as the type `enc_callback_t` argument. The parameter of user callback function may be passed too.

ENC peripheral provides these type of interrupts:

ENC Peripheral Driver

1. Position compare interrupt
2. HOME signal transition interrupt
3. Watchdog time-out interrupt
4. INDEX pulse transition interrupt
5. Roll-under interrupt
6. Roll-over interrupt
7. Simultaneous PHASEA and PHASEB change interrupt

To get a status of any interrupt source use the [ENC_DRV_GetIntMode\(\)](#) function. The flag status reading is provided by the [ENC_DRV_GetStatusFlag\(\)](#) function and by clearing the flag with the [ENC_DRV_ClearStatusFlag\(\)](#) function.

18.3.7 Reading Counters

To read the counters, call the [ENC_DRV_ReadCounters\(\)](#) function and pass the argument of the [enc_counter_t](#) type. This function reads the position difference counter register that causes snapshots of the position, position difference counter and revolution counter registers are each placed into their respective hold registers. Then, the position counter value and revolution counter value are read from their hold registers. These three values are stored into a structure and passed as an argument of the function.

To reset counters (position, position difference, and revolution) use the [ENC_DRV_ResetCounters\(\)](#) function.

18.3.8 Reading Hold Registers

To read an action, such as the trigger input signal, which causes getting snapshots of the position counter, position difference counter, and revolution counter register to their respective hold registers, use the [ENC_DRV_ReadHoldRegisters\(\)](#) function.

Data Structures

- struct [enc_user_config_t](#)
User configuration structure for ENC driver. [More...](#)
- struct [enc_test_config_t](#)
User configuration structure for ENC driver - ENC test module configuration. [More...](#)
- struct [enc_counter_t](#)
Counter registers structure for ENC driver. [More...](#)
- struct [enc_input_monitor_t](#)
Input monitor structure for ENC driver. [More...](#)

Configuration

- [enc_status_t](#) [ENC_DRV_StructInitUserConfigNormal](#) ([enc_user_config_t](#) *userConfigPtr)

- Fills the initial user configuration for the ENC module without the interrupts enablement.*

 - `enc_status_t ENC_DRV_Init` (uint32_t instance, const `enc_user_config_t` *userConfigPtr)

Initializes an ENC instance for operation.
- void `ENC_DRV_Deinit` (uint32_t instance)

De-initializes the ENC peripheral.
- `enc_status_t ENC_DRV_TestInit` (uint32_t instance, const `enc_test_config_t` *userConfigPtr)

Initializes an ENC test module.
- void `ENC_DRV_TestDeinit` (uint32_t instance)

Shuts down the ENC test module, disables test counter, and clears the test period and test count values.
- `enc_status_t ENC_DRV_SetIntMode` (uint32_t instance, `enc_int_source_t` intSrc, bool enable)

Enables/disables the selected ENC interrupt.
- bool `ENC_DRV_GetIntMode` (uint32_t instance, `enc_int_source_t` intSrc)

Gets the configuration of the selected ENC interrupt.
- bool `ENC_DRV_GetStatusFlag` (uint32_t instance, `enc_status_flag_t` flag)

Gets the interrupt status flag of the selected interrupt source.
- void `ENC_DRV_ClearStatusFlag` (uint32_t instance, `enc_status_flag_t` flag)

Clears the status flag of the selected status source.
- `enc_status_t ENC_DRV_ReadCounters` (uint32_t instance, `enc_counter_t` *countRegPtr)

Reads the actual values of the ENC counter registers.
- `enc_status_t ENC_DRV_ReadHoldReg` (uint32_t instance, `enc_counter_t` *holdRegPtr)

Reads the ENC hold registers.
- void `ENC_DRV_ResetCounters` (uint32_t instance)

Resets the ENC counter registers.
- `enc_status_t ENC_DRV_ReadInputMonitor` (uint32_t instance, bool inputMonitorRaw, `enc_input_monitor_t` *inputMonitorPtr)

Reads the ENC input monitor register.

18.3.9 Data Structure Documentation

18.3.9.1 struct enc_user_config_t

Use an instance of this structure with the `ENC_DRV_Init()` function. This enables configuration of the most common settings of the ENC peripheral with a single function call.

Data Fields

- uint32_t `posCntInitValue`
Value to put in Initialization Register.
- uint32_t `posCmpValue`
Value to put in Position Compare Register.
- uint32_t `moduloValue`
Value to put in Modulus Register.
- uint16_t `watchdogTimeout`
Value to put in Watchdog Timeout Register.
- uint8_t `filterCount`
Value represents the number of consecutive samples that must agree prior to the input filter accepting an input transition.
- uint8_t `filterPeriod`

ENC Peripheral Driver

- Value represents the sampling period (in IPBus clock cycles) of the decoder input signals.*

 - `enc_operation_mode_t operationMode`
Operation mode: Normal mode, modulo counting mode or bypass (signal phase count) mode.
 - `bool reverseCounting`
Counting direction: Normal (false) or reverse (true) counting direction.
 - `bool indexInputNegativeEdge`
Type of transition edge of INDEX input signal: positive (false) or negative (true).
 - `bool homeInputNegativeEdge`
Type of transition edge of HOME input signal: positive (false) or negative (true).
 - `bool indexPulsePosInit`
To use HOME (false) or INDEX (true) input to initialize position counter to value in Initialization Register.
 - `bool triggerUpdateHoldRegEnable`
Enable/disable updating hold registers on TRIGGER input.
 - `bool triggerClearPosRegEnable`
Enable/disable clear of position registers on TRIGGER input.
 - `bool moduloRevolutionCounting`
Type of revolution counter - index pulse counting (on false) or modulo counting (on true).
 - `bool outputControlOnReading`
Used to control the behaviour of the POSMATCH output signal.

18.3.9.1.0.96 Field Documentation

18.3.9.1.0.96.1 `bool enc_user_config_t::outputControlOnReading`

True - output control on reading position register, false - OC on match position register.

18.3.9.2 `struct enc_test_config_t`

Use an instance of this structure with the `ENC_DRV_TestInit()` function. This enables configuration of the Test module of the ENC peripheral with a single function call.

Data Fields

- `uint8_t testCount`
Test count - holds the number of quadrature advances to generate.
- `uint8_t testPeriod`
Test period - holds the period of quadrature phase in IPBus clock cycles.
- `bool testNegativeSignalEnable`
Test signal type, positive (false) or negative (true).

18.3.9.2.0.97 Field Documentation

18.3.9.2.0.97.1 `uint8_t enc_test_config_t::testCount`

18.3.9.2.0.97.2 `uint8_t enc_test_config_t::testPeriod`

18.3.9.2.0.97.3 `bool enc_test_config_t::testNegativeSignalEnable`

18.3.9.3 struct `enc_counter_t`

Use an instance of this structure with the `ENC_DRV_ReadHoldRegisters()` or `ENC_DRV_ReadCounters()` functions. This reads counters and hold registers of Position, PositionDifference, Revolution Counter.

Data Fields

- `int32_t position`
Position Counter/Hold Register.
- `int16_t posDiff`
Position Difference Counter/Hold Register.
- `int16_t revolution`
Revolution Counter/Hold Register.

18.3.9.3.0.98 Field Documentation

18.3.9.3.0.98.1 `int32_t enc_counter_t::position`

18.3.9.3.0.98.2 `int16_t enc_counter_t::posDiff`

18.3.9.3.0.98.3 `int16_t enc_counter_t::revolution`

18.3.9.4 struct `enc_input_monitor_t`

Use an instance of this structure with the `ENC_DRV_ReadInputMonitorRegister()`. This reads Input Monitor register that contains the values of the raw or filtered PHASEA, PHASEB, INDEX and HOME input signals.

Data Fields

- `bool phaseA`
PHASEA input.
- `bool phaseB`
PHASEB input.
- `bool index`
INDEX input.
- `bool home`
HOME input.

ENC Peripheral Driver

18.3.9.4.0.99 Field Documentation

18.3.9.4.0.99.1 `bool enc_input_monitor_t::phaseA`

18.3.9.4.0.99.2 `bool enc_input_monitor_t::phaseB`

18.3.9.4.0.99.3 `bool enc_input_monitor_t::index`

18.3.9.4.0.99.4 `bool enc_input_monitor_t::home`

18.3.10 Function Documentation

18.3.10.1 `enc_status_t ENC_DRV_StructInitUserConfigNormal (enc_user_config_t * userConfigPtr)`

This function fills the initial user configuration. Calling the initialization function with the filled parameter configures the ENC module to function as a simple Quadrature Encoder. The settings are:

```
encUserConfig.operationMode = kEncNormalMode;
encUserConfig.reverseCounting = false;
encUserConfig.indexInputNegativeEdge = false;
encUserConfig.homeInputNegativeEdge = false;
encUserConfig.indexPulsePosInit = true;
encUserConfig.posCntInitValue = 0U;
encUserConfig.posCmpValue = 0xFFFFU;
encUserConfig.moduloValue = 0U;
encUserConfig.triggerUpdateHoldRegEnable = false;
encUserConfig.triggerClearPosRegEnable = false;
encUserConfig.moduloRevolutionCounting = false;
encUserConfig.outputControlOnReading = false;
encUserConfig.watchdogTimeout = 0U;
encUserConfig.filterCount = 0U;
encUserConfig.filterPeriod = 0U;
```

Parameters

| | |
|----------------------------|--|
| <code>userConfigPtr</code> | Pointer to the user configuration structure. |
|----------------------------|--|

Returns

Execution status.

18.3.10.2 `enc_status_t ENC_DRV_Init (uint32_t instance, const enc_user_config_t * userConfigPtr)`

This function initializes the run-time state structure to un-gate the clock to the ENC module, initializes the module to user-defined settings and default settings, configures the IRQ state structure, and enables the module-level interrupt to the core. This example shows how to set up the `enc_state_t` and the `enc_user_config_t` parameters and how to call the `ENC_DRV_Init` function by passing in these parameters:

```

enc_user_config_t encUserConfig;
encUserConfig.operationMode = kEncNormalMode;
encUserConfig.reverseCounting = false;
encUserConfig.indexInputNegativeEdge = false;
encUserConfig.homeInputNegativeEdge = false;
encUserConfig.indexPulsePosInit = true;
encUserConfig.posCntInitValue = 0U;
encUserConfig.posCmpValue = 0xFFFFU;
encUserConfig.moduloValue = 0U;
encUserConfig.triggerUpdateHoldRegEnable = false;
encUserConfig.triggerClearPosRegEnable = false;
encUserConfig.moduloRevolutionCounting = false;
encUserConfig.outputControlOnReading = false;
encUserConfig.watchdogTimeout = 0U;
encUserConfig.filterCount = 0U;
encUserConfig.filterPeriod = 0U;
ENC_DRV_Init (&encUserConfig);

```

Parameters

| | |
|----------------------|---|
| <i>instance</i> | ENC instance ID. |
| <i>userConfigPtr</i> | The user configuration structure of type <code>enc_user_config_t</code> . The user is responsible to fill out the members of this structure and to pass the pointer of this structure into this function. |

Returns

Execution status.

18.3.10.3 void ENC_DRV_Deinit (uint32_t instance)

This function shuts down the ENC clock to reduce power consumption.

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | ENC instance ID. |
|-----------------|------------------|

18.3.10.4 enc_status_t ENC_DRV_TestInit (uint32_t instance, const enc_test_config_t * userConfigPtr)

This function initializes the run-time state structure to enable the test module and sets the test period and test count values. This example shows how to set up the `enc_test_config_t` parameters and how to call the `ENC_DRV_TestInit` function by passing in these parameters:

```

enc_test_config_t encTestConfig;
encTestConfig.testNegativeSignalEnable = false;
encTestConfig.testCount = 100;
encTestConfig.testPeriod = 10;
ENC_DRV_TestInit (&encTestConfig);

```

ENC Peripheral Driver

Parameters

| | |
|----------------------|--|
| <i>instance</i> | ENC instance ID. |
| <i>userConfigPtr</i> | The user configuration structure of type enc_test_config_t . |

Returns

Execution status.

18.3.10.5 void ENC_DRV_TestDeinit (uint32_t instance)

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | ENC instance ID. |
|-----------------|------------------|

18.3.10.6 enc_status_t ENC_DRV_SetIntMode (uint32_t instance, enc_int_source_t intSrc, bool enable)

The interrupt source is passing as argument of type [enc_interrupt_source_t](#).

Parameters

| | |
|-----------------|--|
| <i>instance</i> | ENC instance ID. |
| <i>intSrc</i> | The type of interrupt to enable/disable. |
| <i>enable</i> | Bool parameter to enable/disable. |

Returns

Execution status.

18.3.10.7 bool ENC_DRV_GetIntMode (uint32_t instance, enc_int_source_t intSrc)

The interrupt type is passing as an argument of type [enc_int_source_t](#).

Parameters

| | |
|-----------------|---|
| <i>instance</i> | ENC instance ID. |
| <i>intSrc</i> | The type of interrupt to get configuration. |

Returns

Configuration of selected interrupt source.

18.3.10.8 **bool ENC_DRV_GetStatusFlag (uint32_t *instance*, enc_status_flag_t *flag*)**

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | ENC instance ID. |
| <i>flag</i> | Selected type of status flag. |

Returns

State of selected flag.

18.3.10.9 **void ENC_DRV_ClearStatusFlag (uint32_t *instance*, enc_status_flag_t *flag*)**

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | ENC instance ID. |
| <i>flag</i> | Selected type of status flag. |

18.3.10.10 **enc_status_t ENC_DRV_ReadCounters (uint32_t *instance*, enc_counter_t * *countRegPtr*)**

Parameters

| | |
|--------------------|---|
| <i>instance</i> | ENC instance ID. |
| <i>countRegPtr</i> | The structure of ENC counter registers. |

ENC Peripheral Driver

Returns

Execution status.

18.3.10.11 `enc_status_t ENC_DRV_ReadHoldReg (uint32_t instance, enc_counter_t * holdRegPtr)`

Parameters

| | |
|-------------------|--------------------------------------|
| <i>instance</i> | ENC instance ID. |
| <i>holdRegPtr</i> | The structure of ENC hold registers. |

Returns

Execution status.

18.3.10.12 `void ENC_DRV_ResetCounters (uint32_t instance)`

Parameters

| | |
|-----------------|------------------|
| <i>instance</i> | ENC instance ID. |
|-----------------|------------------|

18.3.10.13 `enc_status_t ENC_DRV_ReadInputMonitor (uint32_t instance, bool inputMonitorRaw, enc_input_monitor_t * inputMonitorPtr)`

Parameters

| | |
|------------------------|--|
| <i>instance</i> | ENC instance ID. |
| <i>inputMonitorRaw</i> | The type of input monitor - raw (true) / filtered (false). |
| <i>inputMonitorPtr</i> | The structure of ENC Monitor register variables. |

Returns

Execution status.

Chapter 19

Ethernet MAC (ENET)

19.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Ethernet (ENET) block of Kinetis devices.

Modules

- [ENET HAL driver](#)
- [ENET Peripheral Driver](#)
- [ENET Physical Layer Driver](#)
- [ENET RTCS Adaptor](#)

ENET HAL driver

19.2 ENET HAL driver

19.2.1 Overview

This section describes the programming interface of the ENET HAL driver.

Data Structures

- struct [enet_bd_struct_t](#)
Defines the buffer descriptor structure for the little-endian system and endianness configurable IP. [More...](#)
- struct [enet_config_rmii_t](#)
Defines the RMII/MII configuration structure. [More...](#)
- struct [enet_config_ptp_timer_t](#)
Defines the configuration structure for the IEEE 1588 PTP timer. [More...](#)
- struct [enet_config_tx_fifo_t](#)
Defines the transmit FIFO configuration. [More...](#)
- struct [enet_config_rx_fifo_t](#)
Defines the receive FIFO configuration. [More...](#)
- struct [enet_mib_rx_stat_t](#)
@ brief Defines the receive statistics of MIB [More...](#)
- struct [enet_mib_tx_stat_t](#)
@ brief Defines the transmit statistics of MIB [More...](#)
- struct [enet_special_maccfg_t](#)
Define the special configure for receive and transmit controller. [More...](#)
- struct [enet_mac_config_t](#)
Defines the basic configuration structure for the ENET device. [More...](#)
- struct [enet_bd_config](#)
The configuration structure of buffer descriptor. [More...](#)
- struct [enet_cur_status_t](#)
The structure to save current status. [More...](#)
- struct [enet_bd_attr_t](#)
The buffer descriptor attribute. [More...](#)

Macros

- #define [ENET_ALIGN](#)(x, align) ((unsigned int)((x) + ((align)-1)) & (unsigned int)(~(unsigned int)((align)- 1)))
Defines the system endian type.
- #define [BD_SHORTSWAP](#)(n) (n)
Defines the macro used for byte order change on Buffer descriptor.

Enumerations

- enum enet_status_t { ,
 - kStatus_ENET_InvalidInput,
 - kStatus_ENET_InvalidDevice,
 - kStatus_ENET_InitTimeout,
 - kStatus_ENET_MemoryAllocateFail,
 - kStatus_ENET_GetClockFreqFail,
 - kStatus_ENET_Initialized,
 - kStatus_ENET_Open,
 - kStatus_ENET_Close,
 - kStatus_ENET_Layer2Uninitialized,
 - kStatus_ENET_Layer2OverLarge,
 - kStatus_ENET_Layer2BufferFull,
 - kStatus_ENET_Layer2TypeError,
 - kStatus_ENET_PtpringBufferFull,
 - kStatus_ENET_PtpringBufferEmpty,
 - kStatus_ENET_SMIUninitialized,
 - kStatus_ENET_SMIVisitTimeout,
 - kStatus_ENET_RxbdInvalid,
 - kStatus_ENET_RxbdEmpty,
 - kStatus_ENET_RxbdTrunc,
 - kStatus_ENET_RxbdError,
 - kStatus_ENET_RxBdFull,
 - kStatus_ENET_SmallRxBuffSize,
 - kStatus_ENET_NoEnoughRxBuffers,
 - kStatus_ENET_LargeBufferFull,
 - kStatus_ENET_TxLarge,
 - kStatus_ENET_TxbdFull,
 - kStatus_ENET_TxbdNull,
 - kStatus_ENET_TxBufferNull,
 - kStatus_ENET_NoRxBufferLeft,
 - kStatus_ENET_UnknownCommand,
 - kStatus_ENET_TimeOut,
 - kStatus_ENET_MulticastPointerNull,
 - kStatus_ENET_NoMulticastAddr,
 - kStatus_ENET_AlreadyAddedMulticast,
 - kStatus_ENET_PHYAutoDiscoverFail }

Defines the Status return codes.
 - enum enet_rx_bd_control_status_t {

ENET HAL driver

```

kEnetRxBdEmpty = 0x8000U,
kEnetRxBdRxSoftOwner1 = 0x4000U,
kEnetRxBdWrap = 0x2000U,
kEnetRxBdRxSoftOwner2 = 0x1000U,
kEnetRxBdLast = 0x0800U,
kEnetRxBdMiss = 0x0100U,
kEnetRxBdBroadCast = 0x0080U,
kEnetRxBdMultiCast = 0x0040U,
kEnetRxBdLengthViolation = 0x0020U,
kEnetRxBdNoOctet = 0x0010U,
kEnetRxBdCrc = 0x0004U,
kEnetRxBdOverRun = 0x0002U,
kEnetRxBdTrunc = 0x0001U }

```

Defines the control and status region of the receive buffer descriptor.

- enum `enet_rx_bd_control_extend0_t` {

```

kEnetRxBdIpv4 = 0x0001U,
kEnetRxBdIpv6 = 0x0002U,
kEnetRxBdVlan = 0x0004U,
kEnetRxBdProtocolChecksumErr = 0x0010U,
kEnetRxBdIpHeaderChecksumErr = 0x0020U }

```

Defines the control extended region1 of the receive buffer descriptor.

- enum `enet_rx_bd_control_extend1_t` {

```

kEnetRxBdInterrupt = 0x0080U,
kEnetRxBdUnicast = 0x0100U,
kEnetRxBdCollision = 0x0200U,
kEnetRxBdPhyErr = 0x0400U,
kEnetRxBdMacErr = 0x8000U }

```

Defines the control extended region2 of the receive buffer descriptor.

- enum `enet_tx_bd_control_status_t` {

```

kEnetTx BdReady = 0x8000U,
kEnetTx BdTxSoftOwner1 = 0x4000U,
kEnetTx BdWrap = 0x2000U,
kEnetTx BdTxSoftOwner2 = 0x1000U,
kEnetTx BdLast = 0x0800U,
kEnetTx BdTransmitCrc = 0x0400U }

```

Defines the control status of the transmit buffer descriptor.

- enum `enet_tx_bd_control_extend0_t` {

```

kEnetTx BdTxErr = 0x8000U,
kEnetTx BdTxUnderFlowErr = 0x2000U,
kEnetTx BdExcessCollisionErr = 0x1000U,
kEnetTx BdTxFrameErr = 0x0800U,
kEnetTx BdLatecollisionErr = 0x0400U,
kEnetTx BdOverflowErr = 0x0200U,
kEnetTx TimestampErr = 0x0100U }

```

Defines the control extended region1 of the transmit buffer descriptor.

- enum `enet_tx_bd_control_extend1_t` {

- kEnetTxBdTxBdInterrupt = 0x4000U,
 - kEnetTxBdTimeStamp = 0x2000U }

Defines the control extended region2 of the transmit buffer descriptor.
- enum enet_constant_parameter_t {
 - kEnetMacAddrLen = 6U,
 - kEnetHashValMask = 0x1FU,
 - kEnetMinBuffSize = 256U,
 - kEnetMaxTimeout = 0xFFFFU,
 - kEnetMdcFreq = 2500000U }

Defines the macro to the different ENET constant value.
- enum enet_fifo_configure_t {
 - kEnetMinTxFifoAlmostFull = 6U,
 - kEnetMinFifoAlmostEmpty = 4U,
 - kEnetDefaultTxFifoAlmostFull = 8U }

Defines the normal FIFO configuration for ENET MAC.
- enum enet_mac_operate_mode_t {
 - kEnetMacNormalMode = 0U,
 - kEnetMacSleepMode = 1U }

Defines the normal operating mode and sleep mode for ENET MAC.
- enum enet_config_rmii_mode_t {
 - kEnetCfgMii = 0U,
 - kEnetCfgRmii = 1U }

Defines the RMII or MII mode for data interface between the MAC and the PHY.
- enum enet_config_speed_t {
 - kEnetCfgSpeed100M = 0U,
 - kEnetCfgSpeed10M = 1U }

Defines the 10 Mbps or 100 Mbps speed mode for the data transfer.
- enum enet_config_duplex_t {
 - kEnetCfgHalfDuplex = 0U,
 - kEnetCfgFullDuplex = 1U }

Defines the half or full duplex mode for the data transfer.
- enum enet_mii_write_t {
 - kEnetWriteNoCompliant = 0U,
 - kEnetWriteValidFrame = 1U }

Defines the write operation for the MII.
- enum enet_mii_read_t {
 - kEnetReadValidFrame = 2U,
 - kEnetReadNoCompliant = 3U }

Defines the read operation for the MII.
- enum enet_special_address_filter_t {
 - kEnetSpecialAddressInit = 0U,
 - kEnetSpecialAddressEnable = 1U,
 - kEnetSpecialAddressDisable = 2U }

Defines the initialization, enables or disables the operation for a special address filter.
- enum enet_timer_channel_t {

ENET HAL driver

```
kEnetTimerChannel1 = 0U,
kEnetTimerChannel2 = 1U,
kEnetTimerChannel3 = 2U,
kEnetTimerChannel4 = 3U }
```

Defines the IEEE 1588 timer channel numbers.

- enum `enet_timer_channel_mode_t` {

```
kEnetChannelDisable = 0U,
kEnetChannelRisingCapture = 1U,
kEnetChannelFallingCapture = 2U,
kEnetChannelBothCapture = 3U,
kEnetChannelSoftCompare = 4U,
kEnetChannelToggleCompare = 5U,
kEnetChannelClearCompare = 6U,
kEnetChannelSetCompare = 7U,
kEnetChannelClearCompareSetOverflow = 10U,
kEnetChannelSetCompareClearOverflow = 11U,
kEnetChannelPulseLowonCompare = 14U,
kEnetChannelPulseHighonCompare = 15U }
```

Defines the capture or compare mode for IEEE 1588 timer channels.

- enum `enet_interrupt_request_t` {

```
kEnetBabrInterrupt = 0x40000000U,
kEnetBabtInterrupt = 0x20000000U,
kEnetGraceStopInterrupt = 0x10000000U,
kEnetTxFrameInterrupt = 0x08000000U,
kEnetTxByteInterrupt = 0x04000000U,
kEnetRxFrameInterrupt = 0x02000000U,
kEnetRxByteInterrupt = 0x01000000U,
kEnetMiiInterrupt = 0x00800000U,
kEnetEBusERInterrupt = 0x00400000U,
kEnetLateCollisionInterrupt = 0x00200000U,
kEnetRetryLimitInterrupt = 0x00100000U,
kEnetUnderrunInterrupt = 0x00080000U,
kEnetPayloadRxInterrupt = 0x00040000U,
kEnetWakeupInterrupt = 0x00020000U,
kEnetTsAvailInterrupt = 0x00010000U,
kEnetTsTimerInterrupt = 0x00008000U,
kEnetAllInterrupt = 0x7FFFFFFFU }
```

Defines the RXFRAME/RXBYTE/TXFRAME/TXBYTE/MII/TSTIMER/TSVAAIL interrupt source for ENET.

- enum `enet_irq_number_t` {

```
kEnetTsTimerNumber = 0,
kEnetReceiveNumber = 1,
kEnetTransmitNumber = 2,
kEnetMiiErrorNumber = 3 }
```
- enum `enet_frame_max_t` {

```

kEnetNsecOneSec = 1000000000,
kEnetMaxFrameSize = 1518,
kEnetMaxFrameVlanSize = 1522,
kEnetMaxFrameDateSize = 1500,
kEnetDefaultTruncLen = 2047,
kEnetDefaultIpg = 12,
kEnetMaxValidTxIpg = 27,
kEnetMinValidTxIpg = 8,
kEnetMaxMdioHoldCycle = 7,
kEnetMaxFrameBdNumbers = 6,
kEnetFrameFcsLen = 4,
kEnetEthernetHeadLen = 14,
kEnetEthernetVlanHeadLen = 18 }
    Defines the ENET main constant.
• enum enet_txaccelerator_config_t {
    kEnetTxAccelShift16Enabled = 0x01U,
    kEnetTxAccelIpCheckEnabled = 0x08U,
    kEnetTxAccelProtoCheckEnabled = 0x10U }
    Defines the transmit accelerator configuration.
• enum enet_rxaccelerator_config_t {
    kEnetRxAccelPadRemoveEnabled = 0x01U,
    kEnetRxAccelIpCheckEnabled = 0x02U,
    kEnetRxAccelProtoCheckEnabled = 0x04U,
    kEnetRxAccelMacCheckEnabled = 0x40U,
    kEnetRxAccelShift16Enabled = 0x80U }
    Defines the receive accelerator configuration.
• enum enet_mac_control_flag_t {
    kEnetStopModeEnable = 0x1U ,
    kEnetPayloadlenCheckEnable = 0x4U,
    kEnetRxFlowControlEnable = 0x8U,
    kEnetRxCrcFwdEnable = 0x10U,
    kEnetRxPauseFwdEnable = 0x20U,
    kEnetRxPadRemoveEnable = 0x40U,
    kEnetRxBcRejectEnable = 0x80U,
    kEnetRxPromiscuousEnable = 0x100U,
    kEnetTxCrcFwdEnable = 0x200U,
    kEnetTxCrcBdEnable = 0x400U,
    kEnetMacAddrInsert = 0x800U,
    kEnetTxAccelEnable = 0x1000U,
    kEnetRxAccelEnable = 0x2000U,
    kEnetStoreAndFwdEnable = 0x4000U,
    kEnetMacMibEnable = 0x8000U,
    kEnetSMIPreambleDisable = 0x10000U,
    kEnetVlanTagEnabled = 0x20000U,
    kEnetMacEnhancedEnable = 0x40000U }

```

ENET HAL driver

- Defines the ENET MAC control Configure.*

 - enum `enet_en_dynamical_act_t` {
`kEnGraceSendStop`,
`kEnSendPauseFrame`,
`kEnClearMibCounter` }

The action of mac which should be enabled dynamically.

Functions

- `enet_status_t` `ENET_HAL_Init` (`ENET_Type *base`)
Initializes the ENET module to reset status.
 - void `ENET_HAL_Config` (`ENET_Type *base`, const `enet_mac_config_t *macCfgPtr`, const `uint32_t sysClk`, const `enet_bd_config *bdConfig`)
Configures the ENET.
 - void `ENET_HAL_GetStatus` (`ENET_Type *base`, const `uint32_t mask`, `enet_cur_status_t *curStatus`)
Gets the ENET status.
 - void `ENET_HAL_SetMulticastAddrHash` (`ENET_Type *base`, `uint32_t crcValue`, `enet_special_address_filter_t mode`)
Sets the hardware addressing filtering to a multicast group address.
 - void `ENET_HAL_GetBufDescripAttr` (volatile `enet_bd_struct_t *curBd`, const `uint64_t mask`, `enet_bd_attr_t *resultAttr`)
Gets the attribute field value of buffer descriptor structure and flag status in the control field.
 - `uint8_t *` `ENET_HAL_GetBufDescripData` (volatile `enet_bd_struct_t *curBd`)
Gets the buffer address of the buffer descriptors.
 - void `ENET_HAL_ClrRxBdAfterHandled` (volatile `enet_bd_struct_t *rxBds`, `uint8_t *data`, bool `isbufferUpdate`)
Clears the receive buffer descriptor flag after it has been received or encountered some error in the receiving process.
 - void `ENET_HAL_SetTxBdBeforeSend` (volatile `enet_bd_struct_t *txBds`, `uint16_t length`, bool `isTxTsCfged`, bool `isTxCrcEnable`, bool `isLastOne`)
Sets the transmit buffer descriptor flag before sending a frame.
 - static void `ENET_HAL_ClrTxBdAfterSend` (volatile `enet_bd_struct_t *curBd`)
Clears the context in the transmit buffer descriptors.
 - static void `ENET_HAL_SetRxBdActive` (`ENET_Type *base`)
Activates the receive buffer descriptor.
 - static void `ENET_HAL_SetTxBdActive` (`ENET_Type *base`)
Activates the transmit buffer descriptor.
 - void `ENET_HAL_SetRMII Mode` (`ENET_Type *base`, `enet_config_rmii_t *rmiiCfgPtr`)
Configures the (R)MII data interface of ENET.
 - static `uint32_t` `ENET_HAL_GetSMIData` (`ENET_Type *base`)
Reads data from PHY.
 - void `ENET_HAL_SetSMIRRead` (`ENET_Type *base`, `uint32_t phyAddr`, `uint32_t phyReg`, `enet_mii_read_t operation`)
Sets the Serial Management interface (SMI) read command.
 - void `ENET_HAL_SetSMIWrite` (`ENET_Type *base`, `uint32_t phyAddr`, `uint32_t phyReg`, `enet_mii_write_t operation`, `uint32_t data`)
Sets the SMI write command.

- void [ENET_HAL_EnDynamicalAct](#) (ENET_Type *base, [enet_en_dynamical_act_t](#) action, bool enable)
Enables/disables the Mac dynamical action.
- static void [ENET_HAL_Enable](#) (ENET_Type *base)
Enables the ENET module.
- static void [ENET_HAL_Disable](#) (ENET_Type *base)
Disables the ENET module.
- void [ENET_HAL_SetIntMode](#) (ENET_Type *base, [enet_interrupt_request_t](#) source, bool enable)
Enables/disables the ENET interrupt.
- static void [ENET_HAL_ClearIntStatusFlag](#) (ENET_Type *base, [enet_interrupt_request_t](#) source)
Clears ENET interrupt events.
- static bool [ENET_HAL_GetIntStatusFlag](#) (ENET_Type *base, [enet_interrupt_request_t](#) source)
Gets the ENET interrupt status.
- void [ENET_HAL_Start1588Timer](#) (ENET_Type *base, [enet_config_ptp_timer_t](#) *ptpCfgPtr)
Configures the IEEE 1588 timer and runs the IEEE 1588 timer.
- void [ENET_HAL_Stop1588Timer](#) (ENET_Type *base)
Stops the IEEE 1588 timer.
- static void [ENET_HAL_Adjust1588Timer](#) (ENET_Type *base, uint32_t increaseCorrection, uint32_t periodCorrection)
Adjusts the IEEE 1588 timer.
- static void [ENET_HAL_Set1588TimerNewTime](#) (ENET_Type *base, uint32_t nanSecond)
Sets the IEEE 1588 timer.
- static uint32_t [ENET_HAL_Get1588TimerCurrentTime](#) (ENET_Type *base)
Gets the time from the IEEE 1588 timer.
- static bool [ENET_HAL_Get1588TimerChnStatus](#) (ENET_Type *base, [enet_timer_channel_t](#) channel)
Gets the IEEE 1588 timer channel status.
- static void [ENET_HAL_Rst1588TimerCmpValAndClrFlag](#) (ENET_Type *base, [enet_timer_channel_t](#) channel, uint32_t compareValue)
Resets the IEEE 1588 timer compare value and clears the IEEE 1588 timer channel interrupt flag.

19.2.2 Data Structure Documentation

19.2.2.1 struct enet_bd_struct_t

Data Fields

- uint16_t [length](#)
Buffer descriptor data length.
- uint16_t [control](#)
Buffer descriptor control.
- uint8_t * [buffer](#)
Data buffer pointer.
- uint16_t [controlExtend0](#)
Extend buffer descriptor control0.
- uint16_t [controlExtend1](#)
Extend buffer descriptor control1.
- uint16_t [payloadChecksum](#)
Internal payload checksum.

ENET HAL driver

- uint8_t **headerLength**
Header length.
- uint8_t **protocolType**
Protocol type.
- uint16_t **controlExtend2**
Extend buffer descriptor control2.
- uint32_t **timestamp**
Timestamp.

19.2.2.2 struct enet_config_rmii_t

Data Fields

- enet_config_rmii_mode_t **mode**
RMII/MII mode.
- enet_config_speed_t **speed**
100M/10M Speed
- enet_config_duplex_t **duplex**
Full/Duplex mode.
- bool **isRxOnTxDisabled**
Disable receive and transmit.
- bool **isLoopEnabled**
MII loop mode.

19.2.2.3 struct enet_config_ptp_timer_t

Data Fields

- bool **isSlaveEnabled**
Master or slave PTP timer.
- uint32_t **clockIncease**
Timer increase value each clock period.
- uint32_t **period**
Timer period for generate interrupt event.

19.2.2.4 struct enet_config_tx_fifo_t

Data Fields

- bool **isStoreForwardEnabled**
Transmit FIFO store and forward.
- uint8_t **txFifoWrite**
Transmit FIFO write.
- uint8_t **txEmpty**
Transmit FIFO chapter empty threshold, default zero.
- uint8_t **txAlmostEmpty**
Transmit FIFO chapter almost empty threshold, The minimum value of 4 should be set.
- uint8_t **txAlmostFull**

Transmit FIFO chapter almost full threshold, The minimum value of 6 is required a recommended value of at least 8 should be set.

19.2.2.4.0.100 Field Documentation

19.2.2.4.0.100.1 uint8_t enet_config_tx_fifo_t::txFifoWrite

This should be set when isStoreForwardEnabled is false. this field indicates the number of bytes in step of 64 bytes written to the transmit FiFO before transmission of a frame begins

19.2.2.5 struct enet_config_rx_fifo_t

Data Fields

- uint8_t [rxFull](#)
Receive FIFO chapter full threshold, default zero.
- uint8_t [rxAlmostFull](#)
Receive FIFO chapter almost full threshold, The minimum value of 4 should be set.
- uint8_t [rxEmpty](#)
Receive FIFO chapter empty threshold, default zero.
- uint8_t [rxAlmostEmpty](#)
Receive FIFO chapter almost empty threshold, The minimum value of 4 should be set.

19.2.2.6 struct enet_mib_rx_stat_t

Data Fields

- uint16_t [rxPackets](#)
Receive packets.
- uint16_t [rxBroadcastPackets](#)
Receive broadcast packets.
- uint16_t [rxMulticastPackets](#)
Receive multicast packets.
- uint16_t [rxCrcAlignErrorPackets](#)
Receive packets with CRC/align error.
- uint16_t [rxUnderSizeGoodPackets](#)
Receive packets undersize and good CRC.
- uint16_t [rxUnderSizeBadPackets](#)
Receive packets undersize and bad CRC.
- uint16_t [rxOverSizeGoodPackets](#)
Receive packets oversize and good CRC.
- uint16_t [rxOverSizeBadPackets](#)
Receive packets oversize and bad CRC.
- uint16_t [rxByte64Packets](#)
Receive packets 64-byte.
- uint16_t [rxByte65to127Packets](#)
Receive packets 65-byte to 127-byte.
- uint16_t [rxByte128to255Packets](#)
Receive packets 128-byte to 255-byte.

ENET HAL driver

- [uint16_t rxByte256to511Packets](#)
Receive packets 256-byte to 511-byte.
- [uint16_t rxByte512to1023Packets](#)
Receive packets 512-byte to 1023-byte.
- [uint16_t rxByte1024to2047Packets](#)
Receive packets 1024-byte to 2047-byte.
- [uint16_t rxByteOver2048Packets](#)
Receive packets over 2048-byte.
- [uint32_t rxOctets](#)
Receive octets.
- [uint32_t ieeeOctetsrxFrameOk](#)
Receive octets of received frames OK.
- [uint16_t ieeeRxFrameDrop](#)
Receive frames dropped.
- [uint16_t ieeeRxFrameOk](#)
Receive frames OK.
- [uint16_t ieeeRxFrameCrcErr](#)
Receive frames with CRC error.
- [uint16_t ieeeTxFrameAlignErr](#)
Receive frames with align error.
- [uint16_t ieeeTxFrameMacErr](#)
Receive frames with Mac error.
- [uint16_t ieeeTxFramePause](#)
Receive flow control pause frames.

19.2.2.7 struct enet_mib_tx_stat_t

Data Fields

- [uint16_t txPackets](#)
Transmit packets.
- [uint16_t txBroadcastPackets](#)
Transmit broadcast packets.
- [uint16_t txMulticastPackets](#)
Transmit multicast packets.
- [uint16_t txCrcAlignErrorPackets](#)
Transmit packets with CRC/align error.
- [uint16_t txUnderSizeGoodPackets](#)
Transmit packets undersize and good CRC.
- [uint16_t txUnderSizeBadPackets](#)
Transmit packets undersize and bad CRC.
- [uint16_t txOverSizeGoodPackets](#)
Transmit packets oversize and good CRC.
- [uint16_t txOverSizeBadPackets](#)
Transmit packets oversize and bad CRC.
- [uint16_t txCollision](#)
Transmit packets with collision.
- [uint16_t txByte64Packets](#)
Transmit packets 64-byte.
- [uint16_t txByte65to127Packets](#)

- *Transmit packets 65-byte to 127-byte.*
 • uint16_t [txByte128to255Packets](#)
Transmit packets 128-byte to 255-byte.
- uint16_t [txByte256to511Packets](#)
Transmit packets 256-byte to 511-byte.
- uint16_t [txByte512to1023Packets](#)
Transmit packets 512-byte to 1023-byte.
- uint16_t [txByte1024to2047Packets](#)
Transmit packets 1024-byte to 2047-byte.
- uint16_t [txByteOver2048Packets](#)
Transmit packets over 2048-byte.
- uint32_t [txOctets](#)
Transmit octets.
- uint32_t [ieeeOctetstxFrameOk](#)
Transmit octets of transmitted frames OK.
- uint16_t [ieeetxFrameOk](#)
Transmit frames OK.
- uint16_t [ieeetxFrameOneCollision](#)
Transmit frames with single collision.
- uint16_t [ieeetxFrameMultiCollison](#)
Transmit frames with multicast collision.
- uint16_t [ieeetxFrameLateCollison](#)
Transmit frames with late collision.
- uint16_t [ieeetxFrmaeExcCollison](#)
Transmit frames with excessive collision.
- uint16_t [ieeetxFrameDelay](#)
Transmit frames after deferral delay.
- uint16_t [ieeetxFrameMacErr](#)
Transmit frames with MAC error.
- uint16_t [ieeetxFrameCarrSenseErr](#)
Transmit frames with carrier sense error.
- uint16_t [ieeetxFramePause](#)
Transmit flow control Pause frame.

19.2.2.8 struct enet_special_maccfg_t

Data Fields

- uint16_t [rxMaxFrameLen](#)
Receive maximum frame length.
- uint16_t [rxTruncLen](#)
Receive truncate length, must be greater than or equal to maximum frame length.
- uint16_t [txInterPacketGap](#)
Transmit inter-packet-gap.

ENET HAL driver

19.2.2.9 struct enet_mac_config_t

Data Fields

- [enet_mac_operate_mode_t](#) `macMode`
Mac Normal or sleep mode.
- `uint8_t * macAddr`
MAC hardware address.
- [enet_config_rmii_t](#) * `rmiiCfgPtr`
RMII configure mode.
- `uint32_t macCtlConfigure`
Mac control configure, it is recommended to use `enet_mac_control_flag_t` it is special control set for loop mode, sleep mode, CRC forward/terminate, and so on.
- [enet_config_rx_fifo_t](#) * `rxFifoPtr`
Receive FIFO configuration, if NULL default values will be used.
- [enet_config_tx_fifo_t](#) * `txFifoPtr`
Transmit FIFO configuration, if NULL default values will be used.
- `uint8_t rxAccelerCfg`
Receive accelerator configure, should be set when `kEnetTxAccelEnable` is set.
- `uint8_t txAccelerCfg`
Transmit accelerator configure, should be set when `kEnetRxAccelEnable` is set.
- `uint16_t pauseDuration`
Pause duration, should be set when `kEnetRxFlowControlEnable` is set.
- [enet_special_maccfg_t](#) * `macSpecialCfg`
special configure for MAC to instead of default configure

19.2.2.10 struct enet_bd_config

Data Fields

- volatile [enet_bd_struct_t](#) * `txBds`
The start address of ENET transmit buffer descriptors.
- `uint8_t * txBuffer`
The transmit data buffer start address.
- `uint32_t txBdNumber`
The transmit buffer descriptor numbers.
- `uint32_t txBuffSizeAlign`
The aligned transmit buffer size.
- volatile [enet_bd_struct_t](#) * `rxBds`
The start address of ENET receive buffer descriptors.
- `uint8_t * rxBuffer`
The receive data buffer start address.
- `uint32_t rxBdNumber`
The receive buffer descriptor numbers.
- `uint32_t rxBuffSizeAlign`
The aligned receive transmit buffer size.

19.2.2.10.0.101 Field Documentation
19.2.2.10.0.101.1 volatile enet_bd_struct_t* enet_bd_config::txBds

This address must always be evenly divisible by 16.

19.2.2.10.0.101.2 uint8_t* enet_bd_config::txBuffer

This address must always be evenly divisible by 16.

19.2.2.10.0.101.3 uint32_t enet_bd_config::txBdNumber
19.2.2.10.0.101.4 uint32_t enet_bd_config::txBuffSizeAlign
19.2.2.10.0.101.5 volatile enet_bd_struct_t* enet_bd_config::rxBds

This address must always be evenly divisible by 16.

19.2.2.10.0.101.6 uint8_t* enet_bd_config::rxBuffer

This address must always be evenly divisible by 16.

19.2.2.10.0.101.7 uint32_t enet_bd_config::rxBdNumber
19.2.2.10.0.101.8 uint32_t enet_bd_config::rxBuffSizeAlign
19.2.2.11 struct enet_cur_status_t
Data Fields

- [enet_mib_rx_stat_t rxStatic](#)
The receive static event counter.
- [enet_mib_tx_stat_t txStatic](#)
The transmit static event counter.
- [uint16_t maxFrameLen](#)
The maximum frame length.
- [uint32_t statusFlags](#)
The status flag.

19.2.2.12 struct enet_bd_attr_t
Data Fields

- [uint16_t bdCtl](#)
Buffer descriptor control field.
- [uint16_t rxBdExtCtl](#)
Buffer descriptor extend control field.
- [uint16_t rxBdExtCtl1](#)
Buffer descriptor extend control field 1.
- [uint16_t rxBdExtCtl2](#)

ENET HAL driver

- `uint16_t bdLen`
Buffer descriptor extend control field 2.
- `uint32_t bdTimestamp`
Buffer descriptor data length field.
- `uint64_t flags`
Buffer descriptor time stamp field.
The status flag in the buffer descriptor.

19.2.3 Macro Definition Documentation

19.2.3.1 `#define ENET_ALIGN(x, align) ((unsigned int)((x) + ((align)-1)) & (unsigned int)(~((unsigned int)((align)- 1)))`

Defines the alignment operation.

19.2.4 Enumeration Type Documentation

19.2.4.1 `enum enet_status_t`

Enumerator

- `kStatus_ENET_InvalidInput` Invalid ENET input parameter.
- `kStatus_ENET_InvalidDevice` Invalid ENET device.
- `kStatus_ENET_InitTimeout` ENET initialize timeout.
- `kStatus_ENET_MemoryAllocateFail` Memory allocate failure.
- `kStatus_ENET_GetClockFreqFail` Get clock frequency failure.
- `kStatus_ENET_Initialized` ENET device already initialized.
- `kStatus_ENET_Open` Open ENET device.
- `kStatus_ENET_Close` Close ENET device.
- `kStatus_ENET_Layer2Uninitialized` Layer2 PTP buffer queue uninitialized.
- `kStatus_ENET_Layer2OverLarge` Layer2 packet length over large.
- `kStatus_ENET_Layer2BufferFull` Layer2 packet buffer full.
- `kStatus_ENET_Layer2TypeError` Layer2 packet error type.
- `kStatus_ENET_PtpringBufferFull` PTP ring buffer full.
- `kStatus_ENET_PtpringBufferEmpty` PTP ring buffer empty.
- `kStatus_ENET_SMIUninitialized` SMI uninitialized.
- `kStatus_ENET_SMIVisitTimeout` SMI visit timeout.
- `kStatus_ENET_RxbdInvalid` Receive buffer descriptor invalid.
- `kStatus_ENET_RxbdEmpty` Receive buffer descriptor empty.
- `kStatus_ENET_RxbdTrunc` Receive buffer descriptor truncate.
- `kStatus_ENET_RxbdError` Receive buffer descriptor error.
- `kStatus_ENET_RxBdFull` Receive buffer descriptor full.
- `kStatus_ENET_SmallRxBuffSize` Receive buffer size is so small.
- `kStatus_ENET_NoEnoughRxBuffers` Small receive buffer size.

kStatus_ENET_LargeBufferFull Receive large buffer full.
kStatus_ENET_TxLarge Transmit large packet.
kStatus_ENET_TxbdFull Transmit buffer descriptor full.
kStatus_ENET_TxbdNull Transmit buffer descriptor Null.
kStatus_ENET_TxBufferNull Transmit data buffer Null.
kStatus_ENET_NoRxBufferLeft No more receive buffer left.
kStatus_ENET_UnknownCommand Invalid ENET PTP IOCTL command.
kStatus_ENET_TimeOut ENET timeout.
kStatus_ENET_MulticastPointerNull Null multicast group pointer.
kStatus_ENET_NoMulticastAddr No multicast group address.
kStatus_ENET_AlreadyAddedMulticast Already added to multicast group.
kStatus_ENET_PHYAutoDiscoverFail Failed to automatically discover PHY.

19.2.4.2 enum enet_rx_bd_control_status_t

Enumerator

kEnetRxBdEmpty Empty bit.
kEnetRxBdRxSoftOwner1 Receive software owner.
kEnetRxBdWrap Update buffer descriptor.
kEnetRxBdRxSoftOwner2 Receive software owner.
kEnetRxBdLast Last BD in the frame.
kEnetRxBdMiss Receive for promiscuous mode.
kEnetRxBdBroadCast Broadcast.
kEnetRxBdMultiCast Multicast.
kEnetRxBdLengthViolation Receive length violation.
kEnetRxBdNoOctet Receive non-octet aligned frame.
kEnetRxBdCrc Receive CRC error.
kEnetRxBdOverRun Receive FIFO overrun.
kEnetRxBdTrunc Frame is truncated.

19.2.4.3 enum enet_rx_bd_control_extend0_t

Enumerator

kEnetRxBdIpv4 Ipv4 frame.
kEnetRxBdIpv6 Ipv6 frame.
kEnetRxBdVlan VLAN.
kEnetRxBdProtocolChecksumErr Protocol checksum error.
kEnetRxBdIpHeaderChecksumErr IP header checksum error.

ENET HAL driver

19.2.4.4 enum enet_rx_bd_control_extend1_t

Enumerator

kEnetRxBdInterrupt BD interrupt.
kEnetRxBdUnicast Unicast frame.
kEnetRxBdCollision BD collision.
kEnetRxBdPhyErr PHY error.
kEnetRxBdMacErr Mac error.

19.2.4.5 enum enet_tx_bd_control_status_t

Enumerator

kEnetTxBdReady Ready bit.
kEnetTxBdTxSoftOwner1 Transmit software owner.
kEnetTxBdWrap Wrap buffer descriptor.
kEnetTxBdTxSoftOwner2 Transmit software owner.
kEnetTxBdLast Last BD in the frame.
kEnetTxBdTransmitCrc Receive for transmit CRC.

19.2.4.6 enum enet_tx_bd_control_extend0_t

Enumerator

kEnetTxBdTxErr Transmit error.
kEnetTxBdTxUnderFlowErr Underflow error.
kEnetTxBdExcessCollisionErr Excess collision error.
kEnetTxBdTxFrameErr Frame error.
kEnetTxBdLatecollisionErr Late collision error.
kEnetTxBdOverFlowErr Overflow error.
kEnetTxTimestampErr Timestamp error.

19.2.4.7 enum enet_tx_bd_control_extend1_t

Enumerator

kEnetTxBdTxInterrupt Transmit interrupt.
kEnetTxBdTimeStamp Transmit timestamp flag.

19.2.4.8 enum enet_constant_parameter_t

Enumerator

- kEnetMacAddrLen* ENET mac address length.
- kEnetHashValMask* ENET hash value mask.
- kEnetMinBuffSize* ENET minimum buffer size.
- kEnetMaxTimeout* ENET timeout.
- kEnetMdcFreq* MDC frequency.

19.2.4.9 enum enet_fifo_configure_t

Enumerator

- kEnetMinTxFifoAlmostFull* ENET minimum transmit FIFO almost full value.
- kEnetMinFifoAlmostEmpty* ENET minimum FIFO almost empty value.
- kEnetDefaultTxFifoAlmostFull* ENET default transmit FIFO almost full value.

19.2.4.10 enum enet_mac_operate_mode_t

Enumerator

- kEnetMacNormalMode* Normal operating mode for ENET MAC.
- kEnetMacSleepMode* Sleep mode for ENET MAC.

19.2.4.11 enum enet_config_rmii_mode_t

Enumerator

- kEnetCfgMii* MII mode for data interface.
- kEnetCfgRmii* RMII mode for data interface.

19.2.4.12 enum enet_config_speed_t

Enumerator

- kEnetCfgSpeed100M* Speed 100 M mode.
- kEnetCfgSpeed10M* Speed 10 M mode.

ENET HAL driver

19.2.4.13 enum enet_config_duplex_t

Enumerator

kEnetCfgHalfDuplex Half duplex mode.
kEnetCfgFullDuplex Full duplex mode.

19.2.4.14 enum enet_mii_write_t

Enumerator

kEnetWriteNoCompliant Write frame operation, but not MII compliant.
kEnetWriteValidFrame Write frame operation for a valid MII management frame.

19.2.4.15 enum enet_mii_read_t

Enumerator

kEnetReadValidFrame Read frame operation for a valid MII management frame.
kEnetReadNoCompliant Read frame operation, but not MII compliant.

19.2.4.16 enum enet_special_address_filter_t

Enumerator

kEnetSpecialAddressInit Initializes the special address filter.
kEnetSpecialAddressEnable Enables the special address filter.
kEnetSpecialAddressDisable Disables the special address filter.

19.2.4.17 enum enet_timer_channel_t

Enumerator

kEnetTimerChannel1 IEEE 1588 timer Channel 1.
kEnetTimerChannel2 IEEE 1588 timer Channel 2.
kEnetTimerChannel3 IEEE 1588 timer Channel 3.
kEnetTimerChannel4 IEEE 1588 timer Channel 4.

19.2.4.18 enum enet_timer_channel_mode_t

Enumerator

- kEnetChannelDisable* Disable timer channel.
- kEnetChannelRisingCapture* Input capture on rising edge.
- kEnetChannelFallingCapture* Input capture on falling edge.
- kEnetChannelBothCapture* Input capture on both edges.
- kEnetChannelSoftCompare* Output compare software only.
- kEnetChannelToggleCompare* Toggle output on compare.
- kEnetChannelClearCompare* Clear output on compare.
- kEnetChannelSetCompare* Set output on compare.
- kEnetChannelClearCompareSetOverflow* Clear output on compare, set output on overflow.
- kEnetChannelSetCompareClearOverflow* Set output on compare, clear output on overflow.
- kEnetChannelPulseLowonCompare* Pulse output low on compare for one IEEE 1588 clock cycle.
- kEnetChannelPulseHighonCompare* Pulse output high on compare for one IEEE 1588 clock cycle.

19.2.4.19 enum enet_interrupt_request_t

Enumerator

- kEnetBabrInterrupt* Babbling receive error interrupt source.
- kEnetBabtInterrupt* Babbling transmit error interrupt source.
- kEnetGraceStopInterrupt* Graceful stop complete interrupt source.
- kEnetTxFrameInterrupt* TX FRAME interrupt source.
- kEnetTxByteInterrupt* TX BYTE interrupt source.
- kEnetRxFrameInterrupt* RX FRAME interrupt source.
- kEnetRxByteInterrupt* RX BYTE interrupt source.
- kEnetMiiInterrupt* MII interrupt source.
- kEnetEBusERInterrupt* Ethernet bus error interrupt source.
- kEnetLateCollisionInterrupt* Late collision interrupt source.
- kEnetRetryLimitInterrupt* Collision Retry Limit interrupt source.
- kEnetUnderrunInterrupt* Transmit FIFO underrun interrupt source.
- kEnetPayloadRxInterrupt* Payload Receive interrupt source.
- kEnetWakeupInterrupt* WAKEUP interrupt source.
- kEnetTsAvailInterrupt* TS AVAIL interrupt source.
- kEnetTsTimerInterrupt* TS WRAP interrupt source.
- kEnetAllInterrupt* All interrupt.

19.2.4.20 enum enet_irq_number_t

Enumerator

- kEnetTsTimerNumber* ENET ts_timer IRQ number.

ENET HAL driver

kEnetReceiveNumber ENET receive IRQ number.
kEnetTransmitNumber ENET transmit IRQ number.
kEnetMiiErrorNumber ENET MII error IRQ number.

19.2.4.21 enum enet_frame_max_t

Enumerator

kEnetNsecOneSec NanoSecond in one second.
kEnetMaxFrameSize Maximum frame size.
kEnetMaxFrameVlanSize Maximum VLAN frame size.
kEnetMaxFrameDataSize Maximum frame data size.
kEnetDefaultTruncLen Default Truncate length.
kEnetDefaultIpg ENET default transmit inter packet gap.
kEnetMaxValidTxIpg Maximum valid transmit IPG.
kEnetMinValidTxIpg Minimum valid transmit IPG.
kEnetMaxMdioHoldCycle Maximum hold time clock cycle on MDIO Output.
kEnetMaxFrameBdNumbers Maximum buffer descriptor numbers of a frame.
kEnetFrameFcsLen FCS length.
kEnetEthernetHeadLen Ethernet Frame header length.
kEnetEthernetVlanHeadLen Ethernet VLAN frame header length.

19.2.4.22 enum enet_txaccelerator_config_t

Enumerator

kEnetTxAccelShift16Enabled Transmit FIFO shift-16.
kEnetTxAccelIpChecksumEnabled Insert IP header checksum.
kEnetTxAccelProtoChecksumEnabled Insert protocol checksum.

19.2.4.23 enum enet_rxaccelerator_config_t

Enumerator

kEnetRxAccelPadRemoveEnabled Padding removal for short IP frames.
kEnetRxAccelIpChecksumEnabled Discard with wrong IP header checksum.
kEnetRxAccelProtoChecksumEnabled Discard with wrong protocol checksum.
kEnetRxAccelMacChecksumEnabled Discard with Mac layer errors.
kEnetRxAccelShift16Enabled Receive FIFO shift-16.

19.2.4.24 enum enet_mac_control_flag_t

Enumerator

- kEnetStopModeEnable* ENET Stop mode enable.
- kEnetPayloadLenCheckEnable* Enable MAC to enter hardware freeze when enter debug mode. ENET receive payload length check enable
- kEnetRxFwControlEnable* Enable ENET flow control.
- kEnetRxCrcFwdEnable* Received frame CRC is stripped from the frame.
- kEnetRxPauseFwdEnable* Pause frames are forwarded to the user application.
- kEnetRxPadRemoveEnable* Padding is removed from received frames.
- kEnetRxBcRejectEnable* Broadcast frame reject.
- kEnetRxPromiscuousEnable* Promiscuous mode enabled.
- kEnetTxCrcFwdEnable* Enable transmit frame with the CRC from application.
- kEnetTxCrcBdEnable* When transmit CRC FWD disable, transmit buffer descriptor enable transmit CRC.
- kEnetMacAddrInsert* Enable MAC address insert.
- kEnetTxAccelEnable* Transmit accelerator enable.
- kEnetRxAccelEnable* Transmit accelerator enable.
- kEnetStoreAndFwdEnable* Switcher to enable store and forward.
- kEnetMacMibEnable* Disable MIB module.
- kEnetSMIPreambleDisable* Enable SMI preamble.
- kEnetVlanTagEnabled* Enable VLAN Tag.
- kEnetMacEnhancedEnable* Enable enhanced MAC feature (IEEE 1588 feature/enhanced buff descriptor)

19.2.4.25 enum enet_en_dynamical_act_t

Enumerator

- kEnGraceSendStop* Enable/disable mac to stop the sending process gracefully.
- kEnSendPauseFrame* Enable/disable mac to send the pause frame after current data frame is sent.
- kEnClearMibCounter* Enable/disable mac to clear the MIB counter.

19.2.5 Function Documentation

19.2.5.1 enet_status_t ENET_HAL_Init (ENET_Type * base)

ENET HAL driver

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

Returns

The status of the initialize operation.

- false initialize failure.
- true initialize success.

19.2.5.2 void ENET_HAL_Config (ENET_Type * *base*, const enet_mac_config_t * *macCfgPtr*, const uint32_t *sysClk*, const enet_bd_config * *bdConfig*)

Parameters

| | |
|------------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>macCfgPtr</i> | MAC controller related configuration. |
| <i>sysClk</i> | The system clock |
| <i>bdConfig</i> | buffer descriptor related configuration |

19.2.5.3 void ENET_HAL_GetStatus (ENET_Type * *base*, const uint32_t *mask*, enet_cur_status_t * *curStatus*)

Parameters

| | |
|------------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>mask</i> | The mask represent which status user want to get. |
| <i>curStatus</i> | The structure to save the status result |

19.2.5.4 void ENET_HAL_SetMulticastAddrHash (ENET_Type * *base*, uint32_t *crcValue*, enet_special_address_filter_t *mode*)

This interface is used to add the ENET device to a multicast group address. After joining the group, Mac receives all frames with the group Mac address.

Parameters

| | |
|-----------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>crcValue</i> | The CRC value of the multicast group address. |
| <i>mode</i> | The operation for initialize/enable/disable the specified hardware address. |

19.2.5.5 void ENET_HAL_GetBufDescripAttr (volatile enet_bd_struct_t * *curBd*, const uint64_t *mask*, enet_bd_attr_t * *resultAttr*)

Parameters

| | |
|-------------------|---|
| <i>curBd</i> | The ENET buffer descriptor address. |
| <i>mask</i> | The attribute mask represent which field user want to get. |
| <i>resultAttr</i> | the attribute value which is updated according to the mask value. |

19.2.5.6 uint8_t* ENET_HAL_GetBuffDescripData (volatile enet_bd_struct_t * *curBd*)

Parameters

| | |
|--------------|--------------------------------|
| <i>curBd</i> | The current buffer descriptor. |
|--------------|--------------------------------|

Returns

The buffer address of the buffer descriptor.

19.2.5.7 void ENET_HAL_ClrRxBdAfterHandled (volatile enet_bd_struct_t * *rxBds*, uint8_t * *data*, bool *isbufferUpdate*)

This interface mainly clears the status region and update the buffer pointer of the receive descriptor to a null buffer to ensure that the BD is correctly available to receive data.

Parameters

| | |
|--------------|--|
| <i>rxBds</i> | The current receive buffer descriptor. |
|--------------|--|

ENET HAL driver

| | |
|-----------------------|---|
| <i>data</i> | The data buffer address. This address must be divided by 16 if the <i>isbufferUpdate</i> is set. |
| <i>isbufferUpdate</i> | The data buffer update flag. When you want to update the data buffer of the buffer descriptor ensure that this flag is set. |

19.2.5.8 void ENET_HAL_SetTxBdBeforeSend (volatile enet_bd_struct_t * *txBds*, uint16_t *length*, bool *isTxTsCfged*, bool *isTxCrcEnable*, bool *isLastOne*)

This interface mainly clears the status region of the transmit buffer descriptor to ensure that the BD is correctly available to send. Set the *isTxTsCfged* when the transmit timestamp feature is required.

Parameters

| | |
|----------------------|---|
| <i>txBds</i> | The current transmit buffer descriptor. |
| <i>length</i> | The data length on buffer descriptor. |
| <i>isTxTsCfged</i> | The timestamp configure flag. The timestamp is added to the transmit buffer descriptor when this flag is set. |
| <i>isTxCrcEnable</i> | The flag to transmit CRC sequence after the data byte. <ul style="list-style-type: none"> • True the transmit controller transmits the CRC sequence after the data byte. If the transmit CRC forward from application is disabled this flag should be set to add the CRC sequence. • False the transmit buffer descriptor does not transmit the CRC sequence after the data byte. |
| <i>isLastOne</i> | The last BD flag in a frame. <ul style="list-style-type: none"> • True the last BD in a frame. • False not the last BD in a frame. |

19.2.5.9 static void ENET_HAL_ClrTxBdAfterSend (volatile enet_bd_struct_t * *curBd*) [inline], [static]

Clears the data, length, control, and status region of the transmit buffer descriptor.

Parameters

| | |
|--------------|--------------------------------|
| <i>curBd</i> | The current buffer descriptor. |
|--------------|--------------------------------|

19.2.5.10 static void ENET_HAL_SetRxBdActive (ENET_Type * *base*) [inline], [static]

The buffer descriptor activation should be done after the ENET module is enabled. Otherwise, the activation fails.

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

19.2.5.11 static void ENET_HAL_SetTxBdActive (ENET_Type * *base*) [inline], [static]

The buffer descriptor activation should be done after the ENET module is enabled. Otherwise, the activation fails.

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

19.2.5.12 void ENET_HAL_SetRMII Mode (ENET_Type * *base*, enet_config_rmii_t * *rmiiCfgPtr*)

Parameters

| | |
|-------------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>rmiiCfgPtr</i> | The RMII/MII configuration structure pointer. |

19.2.5.13 static uint32_t ENET_HAL_GetSMIData (ENET_Type * *base*) [inline], [static]

Parameters

ENET HAL driver

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

Returns

The data read from PHY

19.2.5.14 void ENET_HAL_SetSMIRRead (ENET_Type * *base*, uint32_t *phyAddr*, uint32_t *phyReg*, enet_mii_read_t *operation*)

Parameters

| | |
|------------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
| <i>phyAddr</i> | The PHY address. |
| <i>phyReg</i> | The PHY register. |
| <i>operation</i> | The read operation. |

19.2.5.15 void ENET_HAL_SetSMIWrite (ENET_Type * *base*, uint32_t *phyAddr*, uint32_t *phyReg*, enet_mii_write_t *operation*, uint32_t *data*)

Parameters

| | |
|------------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
| <i>phyAddr</i> | The PHY address. |
| <i>phyReg</i> | The PHY register. |
| <i>operation</i> | The write operation. |
| <i>data</i> | The data written to PHY. |

19.2.5.16 void ENET_HAL_EnDynamicalAct (ENET_Type * *base*, enet_en_dynamical_act_t *action*, bool *enable*)

Parameters

| | |
|---------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>action</i> | The action which will be enabled/disabled. |
| <i>enable</i> | The switch to enable/disable the action of the Mac. |

19.2.5.17 static void ENET_HAL_Enable (ENET_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

19.2.5.18 static void ENET_HAL_Disable (ENET_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

19.2.5.19 void ENET_HAL_SetIntMode (ENET_Type * *base*, enet_interrupt_request_t *source*, bool *enable*)

Parameters

| | |
|---------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
| <i>source</i> | The interrupt sources. |
| <i>enable</i> | The interrupt enable switch. |

19.2.5.20 static void ENET_HAL_ClearIntStatusFlag (ENET_Type * *base*, enet_interrupt_request_t *source*) [inline], [static]

Parameters

| | |
|---------------|---|
| <i>base</i> | The ENET peripheral base address. |
| <i>source</i> | The interrupt source to be cleared. enet_interrupt_request_t enum types is recommended as the interrupt source. |

ENET HAL driver

19.2.5.21 static bool ENET_HAL_GetIntStatusFlag (ENET_Type * *base*, enet_interrupt_request_t *source*) [inline], [static]

Parameters

| | |
|---------------|--|
| <i>base</i> | The ENET peripheral base address. |
| <i>source</i> | The interrupt sources. enet_interrupt_request_t enum types is recommended as the interrupt source. |

Returns

The event status of the interrupt source

- true if the interrupt event happened.
- false if the interrupt event has not happened.

19.2.5.22 void ENET_HAL_Start1588Timer (ENET_Type * *base*, enet_config_ptp_timer_t * *ptpCfgPtr*)

This interface configures the IEEE 1588 timer and starts the IEEE 1588 timer. After the timer starts, the IEEE 1588 timer starts incrementing.

Parameters

| | |
|------------------|--|
| <i>base</i> | The ENET peripheral base address. |
| <i>ptpCfgPtr</i> | The IEEE 1588 timer configuration structure pointer. |

19.2.5.23 void ENET_HAL_Stop1588Timer (ENET_Type * *base*)

This interface stops the IEEE 1588 timer and clears its count value.

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

19.2.5.24 static void ENET_HAL_Adjust1588Timer (ENET_Type * *base*, uint32_t *increaseCorrection*, uint32_t *periodCorrection*) [inline], [static]

Adjusts the IEEE 1588 timer according to the increase and correction period of the configured correction.

Parameters

| | |
|----------------------------|--|
| <i>base</i> | The ENET peripheral base address. |
| <i>increase-Correction</i> | The increase correction for IEEE 1588 timer. |
| <i>period-Correction</i> | The period correction for IEEE 1588 timer. |

19.2.5.25 static void ENET_HAL_Set1588TimerNewTime (ENET_Type * *base*, uint32_t *nanSecond*) [inline], [static]

Parameters

| | |
|------------------|--|
| <i>base</i> | The ENET peripheral base address. |
| <i>nanSecond</i> | The nanosecond set to IEEE 1588 timer. |

19.2.5.26 static uint32_t ENET_HAL_Get1588TimerCurrentTime (ENET_Type * *base*) [inline], [static]

Sets the capture command to the IEEE 1588 timer before reading the current time register. After set timer capture, wait for about 1 μ s before reading the captured timer.

Parameters

| | |
|-------------|-----------------------------------|
| <i>base</i> | The ENET peripheral base address. |
|-------------|-----------------------------------|

Returns

the current time from IEEE 1588 timer.

19.2.5.27 static bool ENET_HAL_Get1588TimerChnStatus (ENET_Type * *base*, enet_timer_channel_t *channel*) [inline], [static]

ENET HAL driver

Parameters

| | |
|----------------|-------------------------------------|
| <i>base</i> | The ENET peripheral base address. |
| <i>channel</i> | The IEEE 1588 timer channel number. |

Returns

Compare or capture operation status

- True if the compare or capture has occurred.
- False if the compare or capture has not occurred.

19.2.5.28 `static void ENET_HAL_Rst1588TimerCmpValAndClrFlag (ENET_Type *
base, enet_timer_channel_t channel, uint32_t compareValue) [inline],
[static]`

Parameters

| | |
|---------------------|--|
| <i>base</i> | The ENET peripheral base address. |
| <i>channel</i> | The IEEE 1588 timer channel number. |
| <i>compareValue</i> | Compare value for IEEE 1588 timer channel. |

19.3 ENET Peripheral Driver

19.3.1 Overview

This section describes the programming interface of the ENET Peripheral Driver. The ENET driver receives data from and transmits data to the wired network. The enhanced 1588 feature supports clock synchronization.

19.3.2 ENET device data structure

The ENET device data structure, [enet_dev_if_t](#), includes configuration structure, application structure, and data context structure. This structure should be initialized before the ENET device initialization function. Then, the data structure is passed from the API layer to the device.

19.3.3 ENET Configuration structure

The ENET device data structure uses the [enet_mac_config_t](#) and the [enet_phy_config_t](#) configuration structure for MAC and PHY configurations. This allows users to configure the most common settings of the ENET peripheral. The [enet_mac_config_t](#) mac configuration structure includes the Mac mode, MI-I/RMII mode configuration, MAC controller configuration, receive and transmit accelerator, receive and transmit FIFO, special Mac configuration to receive maximum frame length, receive truncate length, pause duration for pause frame and the PTP slave mode. The [enet_phy_config_t](#) PHY configuration structure includes the PHY address and PHY loop mode, which needs to be configured. If the PHY address is unknown, use the `isAutodiscoverEnabled` flag to find the PHY address. Note:

1. The default maximum frame length is 1518 or 1522(VLAN). The default IPG (inter-packet-gap) is 12 bytes, a sufficient amount for normal Ethernet use. If no special requirements are present, let the `macSpecialCfg` be NULL.
2. The recommended receive and transmit buffer size is the maximum frame size: either 1518 or 1522(VLAN).
3. If the `kEnetTxAccelEnable` and `kEnetRxAccelEnable` are set, ensure that the `txAccelerCfg` and `rxAccelerCfg` are configured.

19.3.4 ENET Buffer data structure

The ENET device data structure uses the [enet_buff_config_t](#) to configure the receive/transmit buffer descriptor numbers and address, the receive/transmit data buffer, the aligned receive/transmit buffer size, the extended receive data buffer queue address and 1588 PTP timestamp data buffer address, etc. Data receive and transmit is easily managed with this context structure.

ENET Peripheral Driver

19.3.5 ENET Initialization

To initialize the ENET module, follow these steps:

1. First, initialize the ENET MAC and PHY configuration structures, and initialize the upper layer callback function for interrupt mode or initialize semaphore `enetIfPtr->enetReceiveSync`, create receive task for poll mode.
2. Call the `enet_mac_init()` function with the `enet_mac_api_t` API structure in the `enet_dev_if_t` and pass in the `enet_dev_if_t` device data structure. This function enables the ENET module.

This is an example code to initialize the ENET device data structure:

```
uint32_t phyAddr;
enet_mac_config_t configMac;
enet_buff_config_t bufferCfg;
enet_config_rmii_t rmiiCfg;
rmiiCfg.duplex = kEnetCfgFullDuplex;
rmiiCfg.speed = kEnetCfgSpeed100M;
rmiiCfg.mode = kEnetCfgRmii;
rmiiCfg.isLoopEnabled = false;
rmiiCfg.isRxOnTxDisabled = false;
memset(&configMac, 0, sizeof(enet_mac_config_t));
configMac.macMode = kEnetMacNormalMode;
configMac.macAddr = source;
configMac.rmiiCfgPtr = &rmiiCfg;
configMac.macCtlConfigure = kEnetRxCrcFwdEnable |
    kEnetTxCrcBdEnable | kEnetMacEnhancedEnable;

// Buffer configure structure//

memset(&bufferCfg, 0, sizeof(enet_buff_config_t));
bufferCfg.rxBdNumber = ENET_RXBD_NUM;
bufferCfg.rxBdPtrAlign = RxBuffDescrip;
bufferCfg.rxBufferAlign = &RxDataBuff[0][0];
bufferCfg.rxBuffSizeAlign = ENET_RXBuffSizeAlign(ENET_RXBUFF_SIZE);
bufferCfg.txBdNumber = ENET_TXBD_NUM;
bufferCfg.txBdPtrAlign = TxBuffDescrip;
bufferCfg.txBufferAlign = &TxDataBuff[0][0];
bufferCfg.txBuffSizeAlign = ENET_TXBuffSizeAlign(ENET_TXBUFF_SIZE);
#if !ENET_RECEIVE_ALL_INTERRUPT
bufferCfg.extRxBuffQue = &ExtRxDataBuff[0][0];
bufferCfg.extRxBuffNum = ENET_EXTRXBD_NUM;
#endif
#if FSL_FEATURE_ENET_SUPPORT_PTP
configMac.isSlaveMode = false;
bufferCfg.ptpTsRxDataPtr = &ptpTsRxData[0];
bufferCfg.ptpTsRxBuffNum = ENET_PTP_RXTS_RING_LEN;
bufferCfg.ptpTsTxDataPtr = &ptpTsTxData[0];
bufferCfg.ptpTsTxBuffNum = ENET_PTP_TXTS_RING_LEN;
#endif

// Set up the PHY configuration structure//

enet_phy_config_t g_enetPhyCfg =
{{0, false }};

// Initialize ENET device//
result = ENET_DRV_Init(enetIfPtr, &configMac, &bufferCfg);
// Initialize PHY//

if(g_enetPhyCfg[device].isAutodiscoverEnabled)
```

```

{
    uint32_t phyAddr;
    result = PHY_DRV_Autodiscover(device, &phyAddr);
    if(result != kStatus_ENET_Success)
        return result;
    enetIfPtr->phyAddr = phyAddr;
}
else
{
    enetIfPtr->phyAddr = g_enetPhyCfg[device].phyAddr;
}

PHY_DRV_Init(device, enetIfPtr->phyAddr, g_enetPhyCfg[device].isLoopEnabled);

// Install ENET stack net interface callback function for receive interrupt mode//

#if ENET_RECEIVE_ALL_INTERRUPT
    ENET_DRV_InstallNetIfCall(enetIfPtr, enet_receive_test);
#else

// Initialize semaphore enetIfPtr->enetReceiveSync and create receive task for poll mode //

osa_status_t osaFlag;
osaFlag = OSA_EventCreate(&enetIfPtr->enetReceiveSync,
    kEventAutoClear);
if(osaFlag != kStatus_OSA_Success)
{
    return osaFlag;
}

/* Create receive task

osaFlag = OSA_TaskCreate(ENET_receive, "receive", ENET_TASK_STACK_SIZE, ENET_receive_stack,
    ENET_RECEIVE_TASK_PRIO, (task_param_t)enetIfPtr, false, &ENET_receive_task_handler);
if(osaFlag != kStatus_OSA_Success)
{
    return osaFlag;
}
}
#endif

```

19.3.6 ENET Data Receive

ENET can receive data in two different ways. The MACRO `ENET_RECEIVE_ALL_INTERRUPT` selects the way in which data is received.

- interrupt and poll (define `ENET_RECEIVE_ALL_INTERRUPT` with 0)
- interrupt only (define `ENET_RECEIVE_ALL_INTERRUPT` with 1)

Poll approach (Interrupt add task poll) for Mac receive: The ENET driver receives data directly from the buffer descriptor to the upper layer. To shorten the receiving process time on the receive interrupt, the receive data uses the interrupt and poll combination:

1. Receive interrupt: releases the receive synchronize signal (`enetReceiveSync`).
2. Poll: receives task and waits for the receive synchronize signal when no data is received. The receive data returns the address and data length of the received data. To receive data from the ENET device, create a receive task as follows:

```

// Create the task when do net device initialize//

task_create(ENET_receive, ENET_TEST_TASK_PRIO, enetIfPtr, &revHandle);

```

ENET Peripheral Driver

```

.....

ENET_receive(void *param)
{
    uint8_t *packet;
    uint16_t length;
    uint16_t counter;
    enet_mac_packet_buffer_t packetBuffer[
kEnetMaxFrameBdNumbers];

    enet_dev_if_t * enetIfPtr = (enet_dev_if_t *)param;
    while(1)
    {

        // Receive frame//

        result = ENET_DRV_ReceiveData(enetIfPtr, packetBuffer);
        if ((result == kStatus_ENET_RxbdEmpty) || (result ==
kStatus_ENET_InvalidInput))
#ifdef !USE_RTOS
        {
            status = OSA_EventWait (&enetIfPtr->enetReceiveSync, flag, false, 0, &flagCheck);
        }
        else if(result == kStatus_ENET_Success)
        {
#else
        {
            OSA_EventWait (&enetIfPtr->enetReceiveSync, flag, false,
OSA_WAIT_FOREVER, &flagCheck);
        }
#endif
    }

    .....

    // The packets delivery to upper layer and do data buffer enqueue after the data copied to the
upper layer buffer//

    if (packetBuffer[0].data != NULL)
    {

        // Collect the frame first to the packet which is the data buffer for upper layer//

        length = 0;
        for(counter = 0; packetBuffer[counter].length != 0 ; counter ++)
        {
            memcpy(packet + length, packetBuffer[counter].data, packetBuffer[counter].length);
            length += packetBuffer[counter].length;
            (uint32_t *) (packetBuffer[counter].data) = 0;

            // data buffers are required to enqueued to the extended receive buffer queue//

            enet_mac_enqueue_buffer((void **)&enetIfPtr->
bdContext.extRxBuffQue, packetBuffer[counter].data);
            packetBuffer[counter].length = 0;
        }

        // call upper layer receive function//

        .....
    }
}
</code>

```

```

// Receive interrupt handler to wake up blocked receive task//
<code>
void ENET_DRV_RxIRQHandler(uint32_t instance)
{
    enet_dev_if_t *enetIfPtr;
    uint32_t baseAddr;
    enetIfPtr = enetIfHandle[instance];
    event_flags_t flag = 0x1;

    //Check input parameter//

    if (!enetIfPtr)
    {
        return;
    }
    baseAddr = g_enetBaseAddr[enetIfPtr->deviceNumber];

    // Get interrupt status.//

    while ((ENET_HAL_GetIntStatusFlag(baseAddr,
        kEnetRxFrameInterrupt)) || (ENET_HAL_GetIntStatusFlag(
        baseAddr, kEnetRxByteInterrupt)))
    {

        //Clear interrupt//

        ENET_HAL_ClearIntStatusFlag(baseAddr,
            kEnetRxFrameInterrupt);
        ENET_HAL_ClearIntStatusFlag(baseAddr,
            kEnetRxByteInterrupt);

        // Release sync signal-----//

        OSA_EventSet(&enetIfPtr->enetReceiveSync, flag);
    }
}

```

Note: The extended receive buffer queue is required in the structure when using the receive polling mode. The data buffer in receive polling mode has to be enqueued by the end of each receive time.

Interrupt only approach for Mac receive: The ENET driver receives data directly from the buffer descriptor to the upper layer. In this case, data is received on the receive interrupt handler:

1. Receive interrupt handler calls the receive peripheral driver.
2. Receive peripheral driver calls the initialized callback function.
3. The callback function checks the protocol and delivers the received data to the upper layer of the TCP/IP stack.

These are the details:

```

void ENET_DRV_RxIRQHandler(uint32_t instance)
{
    enet_dev_if_t *enetIfPtr;
    uint32_t baseAddr;
    enetIfPtr = enetIfHandle[instance];

    //Check input parameter//

    if (!enetIfPtr)
    {
        return;
    }
    baseAddr = g_enetBaseAddr[enetIfPtr->deviceNumber];

```

ENET Peripheral Driver

```

// Get interrupt status.//

while ((ENET_HAL_GetIntStatusFlag(baseAddr,
    kEnetRxFrameInterrupt)) || (ENET_HAL_GetIntStatusFlag(
    baseAddr, kEnetRxByteInterrupt)))
{
    //Clear interrupt//

    ENET_HAL_ClearIntStatusFlag(baseAddr,
    kEnetRxFrameInterrupt);
    ENET_HAL_ClearIntStatusFlag(baseAddr,
    kEnetRxByteInterrupt);

    // Receive peripheral driver//

    ENET_DRV_ReceiveData(enetIfPtr);
}

}

</code>
.....

<code>
uint32_t ENET_DRV_ReceiveData(enet_dev_if_t *enetIfPtr)
{
    void *curBd;
    uint32_t length;
    uint8_t *packet;
    uint32_t controlStatus;

    // Check input parameters//

    if(!enetIfPtr)
    {
        return kStatus_ENET_InvalidInput;
    }

    .....

    // callback function to delivery to stack upper layer //

    enetIfPtr->enetNetifcall(enetIfPtr, packet, length);

    .....

    return kStatus_ENET_Success;
}

</code>

<code>
uint32_t void enet_callback(void *param, enet_mac_packet_buffer_t *packetBuffer)
{
    uint32_t length = 0;
    uint16_t type, counter = 0;
    uint8_t *packet;

    // Collect the frame first//

    if(!packetBuffer[1].length)
    {
        packet = packetBuffer[0].data;
        length = packetBuffer[0].length;
    }
}

```

```

}
else
{
    // Dequeue a large buffer //

    packet = enet_mac_dequeue_buffer((void *)&dataBuffQue);
    if(packet!=NULL)
    {
        for(counter = 0; packetBuffer[counter].next != NULL ; counter ++)
        {
            memcpy(packet + length, packetBuffer[counter].data, packetBuffer[counter].length);
            length += packetBuffer[counter].length;
        }
    }
    else
    {
        return kStatus_ENET_LargeBufferFull;
    }
}

// Process the received frame//
type = ntohs(*(uint16_t *)&((enet_etherent_header_t *)packet)->type);
// Collect frame to PCB structure for upper layer process//

QUEUEGET(packbuffer[enetIfPtr->deviceNumber].pcbHead,packbuffer[enetIfPtr->
deviceNumber].pcbTail, pcbPtr);
if(pcbPtr)
{
    pcbPtr->FRAG[0].LENGTH = length;
    pcbPtr->FRAG[0].FRAGMENT = packet;
    pcbPtr->PRIVATE = (void *)enetIfPtr;

    switch(type)
    {
        case ENETPROT_IP:
            IPE_rcv_IP((PCB *)pcbPtr,enetIfPtr->netIfPtr);
            break;
        case ENETPROT_ARP:
            IPE_rcv_ARP((PCB *)pcbPtr,enetIfPtr->netIfPtr);
            break;
        case ENETPROT_IP6:
            IP6E_rcv_IP((PCB *)pcbPtr,enetIfPtr->netIfPtr);
            break;
        case ENETPROT_ETHERNET:
            enet_ptp_service_l2packet(enetIfPtr, packet, length);
            break;
        default:
            PCB_free((PCB *)pcbPtr);
            break;
    }
}
else
{
    enetIfPtr->stats.statsRxMissed++;
}
}

```

Remember to enqueue the packet to the dataBuffQue and enqueue the pcbPtr to the packbuffer after the data is processed by the upper layer. This process is done in the ENET_free API and called by the RTCS.
 //

ENET Peripheral Driver

19.3.7 ENET Data Transmit

Data Transmit transmits data from the TCP/IP layer to the device and, then, to the network. The data transmit function should be used as follows: PCB_PTR is the data buffer structure of the frame which contains many PCB_FRAGMENT(including the data buffer and length).

```
uint32_t ENET_send(_enet_handle handle, PCB_PTR packet, uint32_t type, _enet_address dest, uint32_t flags)
{
    uint8_t headerLen, *frame;
    PCB_FRAGMENT *fragPtr;
    uint16_t size = 0, lenTemp = 0, bdNumUsed = 0;
    enet_dev_if_t *enetIfPtr;
    enet_ethernet_header_t *packetPtr;
    volatile enet_bd_struct_t * curBd;
    uint32_t result, lenoffset = 0;

    //Check out//

    if ((!handle) || (!packet))
    {
        return kStatus_ENET_InvalidInput;
    }

    enetIfPtr = (enet_dev_if_t *)handle;

    // Default frame header size//
    headerLen = kEnetEthernetHeadLen;

    // Check the frame length//

    for (fragPtr = packet->FRAG; fragPtr->LENGTH; fragPtr++)
    {
        size += fragPtr->LENGTH;
    }
    if (size > enetIfPtr->maxFrameSize)
    {
        return kStatus_ENET_TxLarge;
    }

    //Add MAC hardware address//

    packetPtr = (enet_ethernet_header_t *)packet->FRAG[0].FRAGMENT;
    hton(packetPtr->destAddr, dest);
    hton(packetPtr->sourceAddr, enetIfPtr->macAddr);
    packetPtr->type = HTONS(type);
    if (flags & ENET_OPT_8021QTAG)
    {
        enet_8021vlan_header_t *vlanHeadPtr = (
            enet_8021vlan_header_t *)packetPtr;
        vlanHeadPtr->tpidtag = HTONS(ENETPROT_8021Q);
        vlanHeadPtr->othertag = HTONS((ENET_GETOPT_8021QPRIORIO(flags) << 13));
        vlanHeadPtr->type = HTONS(type);
        headerLen = sizeof(enet_8021vlan_header_t);
        packet->FRAG[0].LENGTH = headerLen;
    }

    if (flags & ENET_OPT_8023)
    {
        enet_8022_header_ptr lcPtr = (enet_8022_header_ptr)(packetPtr->type + 2);
        packetPtr->type = HTONS(size - headerLen);
        lcPtr->dsap[0] = 0xAA;
        lcPtr->ssap[0] = 0xAA;
        lcPtr->command[0] = 0x03;
        lcPtr->oui[0] = 0x00;
    }
}
```

```

    lcPtr->oui[1] = 0x00;
    lcPtr->oui[2] = 0x00;
    lcPtr->type = HTONS(type);
    packet->FRAG[0].LENGTH = packet->FRAG[0].LENGTH+ sizeof(enet_8022_header_t);
}

// Get the current transmit data buffer in buffer descriptor //

curBd = enetIfPtr->bdContext.txBdCurPtr;
frame = ENET_HAL_GetBuffDescripData(curBd);

// Send a whole frame with a signal buffer//

if(size <= enetIfPtr->bdContext.txBuffSizeAlign)
{
    bdNumUsed = 1;
    for (fragPtr = packet->FRAG; fragPtr->LENGTH; fragPtr++)
    {
        memcpy(frame + lenTemp, fragPtr->FRAGMENT, fragPtr->LENGTH);
        lenTemp += fragPtr->LENGTH;
    }

    // Send packet to the device//

    return ENET_DRV_SendData(enetIfPtr, size, bdNumUsed);
}

// Copy the Ethernet header first//
memcpy(frame, packet->FRAG[0].FRAGMENT, packet->FRAG[0].LENGTH);

// Send a whole frame with multiple buffer descriptors//

while((size - bdNumUsed* enetIfPtr->bdContext.txBuffSizeAlign) > enetIfPtr->
    bdContext.txBuffSizeAlign)
{
    if(bdNumUsed == 0)
    {
        memcpy((void *) (frame + packet->FRAG[0].LENGTH), (void *) (packet->FRAG[1].FRAGMENT), enetIfPtr
->bdContext.txBuffSizeAlign - packet->FRAG[0].LENGTH);
        lenoffset += (enetIfPtr->bdContext.txBuffSizeAlign - packet->FRAG[0].
LENGTH);
    }
    else
    {
        memcpy((void *) frame, (void *) (packet->FRAG[1].FRAGMENT + lenoffset), enetIfPtr->
bdContext.txBuffSizeAlign);
        lenoffset += enetIfPtr->bdContext.txBuffSizeAlign;
    }

    // Increment the buffer descriptor//

    curBd = ENET_DRV_IncrTxBuffDescripIndex(enetIfPtr, curBd);
    frame = ENET_HAL_GetBuffDescripData(curBd);

    // Increment the index and parameters//

    bdNumUsed ++;
}
memcpy((void *) frame, (void *) (packet->FRAG[1].FRAGMENT + lenoffset), size - bdNumUsed * enetIfPtr->
    bdContext.txBuffSizeAlign);
bdNumUsed ++;

// Send packet to the device//

result = ENET_DRV_SendData(enetIfPtr, size, bdNumUsed);

// Free the PCB buffer if necessary//

```

ENET Peripheral Driver

```
PCB_free(packet);
return result;
}
```

19.3.8 ENET Note:

- TWR-MK70F120M Tower System module routes the RMIi interface signals from the CPU board to the primary connectors. Hence, the `rmiiCfgMode` in the `enet_mac_config_t` should be set to the `kEnetCfgRmii`. TWR-MK64F120M module can configure both RMIi and MII modes.
- Jumper settings When ENET is uses the RMIi interface signals by default, the RMIi input clock must be kept in phase with the clock supplied to the external PHY. Jumpers should be set as follows:
 - TWR-SER J2 shunt across 3-4 , J3 shunt across 2-3, J12 shunt across 9-10
 - TWR-MK64f120M board make sure J32 jumper is on to disable the OSC on the CPU board.
 - TWR-MK70f120M board make sure J18 jumper is on to disable the OSC on the CPU board.
 When ENET chooses the MII interface signals, the jumper should be set as follows: TWR-SER J2 shunt across 1-2, J12 no shunt across 9-10.
- In case there exists the cache for memory, when do transfer data, user have to make sure the data's consistence. That means, when reading the data from memory, application should be sure the data that from or to memory device is actually what it is to be and not cached.

Data Structures

- struct `enet_multicast_group_t`
Defines the multicast group structure for the ENET device. [More...](#)
- struct `enet_ethernet_header_t`
Defines the ENET header structure. [More...](#)
- struct `enet_8021vlan_header_t`
Defines the ENET VLAN frame header structure. [More...](#)
- struct `enet_buff_descrip_context_t`
Defines the structure for ENET buffer descriptors status. [More...](#)
- struct `enet_stats_t`
Defines the ENET packets statistic structure. [More...](#)
- struct `enet_mac_packet_buffer_t`
Defines the ENET MAC packet buffer structure. [More...](#)
- struct `enet_buff_config_t`
Defines the receive buffer descriptor configure structure. [More...](#)
- struct `enet_dev_if_t`
Defines the ENET device data structure for the ENET. [More...](#)
- struct `enet_user_config_t`
Defines the ENET user configuration structure. [More...](#)

Macros

- `#define ENET_RECEIVE_ALL_INTERRUPT 1`

- *Defines the approach: ENET interrupt handler receive.*
- #define `ENET_ENABLE_DETAIL_STATS` 0
Defines the statistic enable macro.
- #define `ENET_HTONS(n) __REV16(n)`
brief Defines the macro for converting constants from host byte order to network byte order
- #define `ENET_ORIGINAL_CRC32` 0xFFFFFFFFU
Defines the CRC-32 calculation constant.
- #define `ENET_CRC32_POLYNOMIC` 0xEDB88320U
CRC-32 Polynomic.

Enumerations

- enum `enet_crc_parameter_t` {
 `kEnetCrcOffset` = 8,
 `kEnetCrcMask1` = 0x3F }
Defines the CRC data for a hash value calculation.
- enum `enet_protocol_type_t` {
 `kEnetProtocol2ptpv2` = 0x88F7,
 `kEnetProtocolIpv4` = 0x0800,
 `kEnetProtocolIpv6` = 0x86dd,
 `kEnetProtocol8021QVlan` = 0x8100,
 `kEnetPacketUdpVersion` = 0x11,
 `kEnetPacketIpv4Version` = 0x4,
 `kEnetPacketIpv6Version` = 0x6 }
Defines the ENET protocol type and main parameters.

Variables

- ENET_Type *const `g_enetBase` []
Array for ENET module register base address.
- const IRQn_Type `g_enetTxIrqId` []
Two-dimensional array for the ENET interrupt vector number.

ENET Driver

- `enet_status_t` `ENET_DRV_Init` (`enet_dev_if_t` *enetIfPtr, const `enet_user_config_t` *userConfig)
Initializes the ENET with the basic configuration.
- `enet_status_t` `ENET_DRV_Deinit` (`enet_dev_if_t` *enetIfPtr)
De-initializes the ENET device.
- `enet_status_t` `ENET_DRV_UpdateRxBuffDescrip` (`enet_dev_if_t` *enetIfPtr, bool isBuffUpdate)
Updates the receive buffer descriptor.
- `enet_status_t` `ENET_DRV_CleanupTxBuffDescrip` (`enet_dev_if_t` *enetIfPtr)
ENET transmit buffer descriptor cleanup.
- volatile `enet_bd_struct_t` * `ENET_DRV_IncrRxBuffDescripIndex` (`enet_dev_if_t` *enetIfPtr, volatile `enet_bd_struct_t` *curBd)
Increases the receive buffer descriptor to the next one.

ENET Peripheral Driver

- volatile `enet_bd_struct_t * ENET_DRV_IncrTxBuffDescripIndex` (`enet_dev_if_t *enetIfPtr`, volatile `enet_bd_struct_t *curBd`)
Increases the transmit buffer descriptor to the next one.
- bool `ENET_DRV_RxErrorStats` (`enet_dev_if_t *enetIfPtr`, volatile `enet_bd_struct_t *curBd`)
Processes the ENET receive frame error statistics.
- void `ENET_DRV_TxErrorStats` (`enet_dev_if_t *enetIfPtr`, volatile `enet_bd_struct_t *curBd`)
Processes the ENET transmit frame statistics.
- `enet_status_t ENET_DRV_ReceiveData` (`enet_dev_if_t *enetIfPtr`)
Receives ENET packets.
- `enet_status_t ENET_DRV_InstallNetIfCall` (`enet_dev_if_t *enetIfPtr`, `enet_netif_callback_t` function)
Installs ENET TCP/IP stack net interface callback function.
- `enet_status_t ENET_DRV_SendData` (`enet_dev_if_t *enetIfPtr`, `uint32_t dataLen`, `uint32_t bdNumUsed`)
Transmits ENET packets.
- void `ENET_DRV_RxIRQHandler` (`uint32_t instance`)
The ENET receive interrupt handler.
- void `ENET_DRV_TxIRQHandler` (`uint32_t instance`)
The ENET transmit interrupt handler.
- void `ENET_DRV_CalculateCrc32` (`uint8_t *address`, `uint32_t *crcValue`)
Calculates the CRC hash value.
- `enet_status_t ENET_DRV_AddMulticastGroup` (`uint32_t instance`, `uint8_t *address`, `uint32_t *hash`)
Adds the ENET device to a multicast group.
- `enet_status_t ENET_DRV_LeaveMulticastGroup` (`uint32_t instance`, `uint8_t *address`)
Moves the ENET device from a multicast group.
- void `enet_mac_enqueue_buffer` (`void **queue`, `void *buffer`)
ENET buffer enqueue.
- void * `enet_mac_dequeue_buffer` (`void **queue`)
ENET buffer dequeue.

19.3.9 Data Structure Documentation

19.3.9.1 struct enet_multicast_group_t

Data Fields

- `uint8_t groupAdddr` [`kEnetMacAddrLen`]
Multicast group address.
- `uint32_t hash`
Hash value of the multicast group address.
- struct `ENETMulticastGroup * next`
Pointer of the next group structure.
- struct `ENETMulticastGroup * prv`
Pointer of the previous structure.

19.3.9.2 struct enet_ethernet_header_t

Data Fields

- uint8_t **destAddr** [kEnetMacAddrLen]
Destination address.
- uint8_t **sourceAddr** [kEnetMacAddrLen]
Source address.
- uint16_t **type**
Protocol type.

19.3.9.3 struct enet_8021vlan_header_t

Data Fields

- uint8_t **destAddr** [kEnetMacAddrLen]
Destination address.
- uint8_t **sourceAddr** [kEnetMacAddrLen]
Source address.
- uint16_t **tpidtag**
ENET 8021tag header tag region.
- uint16_t **othertag**
ENET 8021tag header type region.
- uint16_t **type**
Protocol type.

19.3.9.4 struct enet_buff_descrip_context_t

Data Fields

- volatile **enet_bd_struct_t * rxBdBasePtr**
Receive buffer descriptor base address pointer.
- volatile **enet_bd_struct_t * rxBdCurPtr**
Current receive buffer descriptor pointer.
- volatile **enet_bd_struct_t * rxBdDirtyPtr**
Receive dirty buffer descriptor.
- volatile **enet_bd_struct_t * txBdBasePtr**
Transmit buffer descriptor base address pointer.
- volatile **enet_bd_struct_t * txBdCurPtr**
Current transmit buffer descriptor pointer.
- volatile **enet_bd_struct_t * txBdDirtyPtr**
Last cleaned transmit buffer descriptor pointer.
- bool **isTxBdFull**
Transmit buffer descriptor full.
- bool **isRxBdFull**
Receive buffer descriptor full.
- uint32_t **rxBuffSizeAlign**
Receive buffer size alignment.
- uint32_t **txBuffSizeAlign**

ENET Peripheral Driver

- *Transmit buffer size alignment.*
- `uint8_t * extRxBuffQue`
Extended Rx data buffer queue to update the data buff in the receive buffer descriptor.
- `uint8_t extRxBuffNum`
extended data buffer number

19.3.9.5 struct enet_stats_t

Data Fields

- `uint32_t statsRxTotal`
Total number of receive packets.
- `uint32_t statsTxTotal`
Total number of transmit packets.

19.3.9.6 struct enet_mac_packet_buffer_t

Data Fields

- `uint8_t * data`
Data buffer pointer.
- `uint16_t length`
Data length.
- `struct ENETMacPacketBuffer * next`
Next pointer.

19.3.9.7 struct enet_buff_config_t

Data Fields

- `uint16_t rxBdNumber`
Receive buffer descriptor number.
- `uint16_t txBdNumber`
Transmit buffer descriptor number.
- `uint32_t rxBuffSizeAlign`
Aligned receive buffer size and must be larger than 256.
- `uint32_t txBuffSizeAlign`
Aligned transmit buffer size and must be larger than 256.
- `volatile enet_bd_struct_t * rxBdPtrAlign`
Aligned receive buffer descriptor pointer.
- `uint8_t * rxBufferAlign`
Aligned receive data buffer pointer.
- `volatile enet_bd_struct_t * txBdPtrAlign`
Aligned transmit buffer descriptor pointer.
- `uint8_t * txBufferAlign`
Aligned transmit buffer descriptor pointer.
- `uint8_t * extRxBuffQue`
Extended Rx data buffer queue to update the data buff in the receive buffer descriptor.

- `uint8_t extRxBuffNum`
extended data buffer number

19.3.9.8 struct enet_dev_if_t

Data Fields

- `struct ENETDevIf * next`
Next device structure address.
- `void * netIfPrivate`
For upper layer private structure.
- `enet_multicast_group_t * multiGroupPtr`
Multicast group chain.
- `uint32_t deviceNumber`
Device number.
- `uint8_t macAddr [kEnetMacAddrLen]`
Mac address.
- `uint8_t phyAddr`
PHY address connected to this device.
- `bool isInitialized`
Device initialized.
- `uint16_t maxFrameSize`
Mac maximum frame size.
- `bool isVlanTagEnabled`
ENET VLAN-TAG frames enabled.
- `bool isTxCrcEnable`
Transmit CRC enable in buffer descriptor.
- `bool isRxCrcFwdEnable`
Receive CRC forward.
- `enet_buff_descrip_context_t bdContext`
Mac buffer descriptors context pointer.
- `enet_stats_t stats`
Packets statistic.
- `enet_netif_callback_t enetNetifcall`
Receive callback function to the upper layer.
- `mutex_t enetContextSync`
Sync signal.

19.3.9.9 struct enet_user_config_t

Data Fields

- `const enet_mac_config_t * macCfgPtr`
MAC configuration structure.
- `const enet_buff_config_t * buffCfgPtr`
ENET buffer configuration structure.

ENET Peripheral Driver

19.3.10 Macro Definition Documentation

19.3.10.1 **#define ENET_ENABLE_DETAIL_STATS 0**

19.3.10.2 **#define ENET_ORIGINAL_CRC32 0xFFFFFFFFFU**

CRC-32 Original data

19.3.11 Enumeration Type Documentation

19.3.11.1 **enum enet_crc_parameter_t**

Enumerator

kEnetCrcOffset CRC-32 offset2.

kEnetCrcMask1 CRC-32 mask.

19.3.11.2 **enum enet_protocol_type_t**

Enumerator

kEnetProtocoll2ptpv2 Packet type Ethernet ieee802.3.

kEnetProtocollpv4 Packet type IPv4.

kEnetProtocollpv6 Packet type IPv6.

kEnetProtocol8021QVlan Packet type VLAN.

kEnetPacketUdpVersion UDP protocol type.

kEnetPacketIpv4Version Packet IP version IPv4.

kEnetPacketIpv6Version Packet IP version IPv6.

19.3.12 Function Documentation

19.3.12.1 **enet_status_t ENET_DRV_Init (enet_dev_if_t * *enetIfPtr*, const enet_user_config_t * *userConfig*)**

Parameters

| | |
|------------------|--|
| <i>enetIfPtr</i> | The pointer to the basic Ethernet structure. |
|------------------|--|

| | |
|-------------------|--|
| <i>userConfig</i> | The ENET user configuration structure pointer. |
|-------------------|--|

Returns

The execution status.

19.3.12.2 **enet_status_t** ENET_DRV_Deinit (**enet_dev_if_t** * **enetIfPtr**)

Parameters

| | |
|------------------|-----------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
|------------------|-----------------------------|

Returns

The execution status.

19.3.12.3 **enet_status_t** ENET_DRV_UpdateRxBuffDescrip (**enet_dev_if_t** * **enetIfPtr**, **bool** **isBuffUpdate**)

This function updates the used receive buffer descriptor ring to ensure that the used BDS is correctly used. It cleans the status region and sets the control region of the used receive buffer descriptor. If the `isBufferUpdate` flag is set, the data buffer in the buffer descriptor is updated.

Parameters

| | |
|---------------------|------------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>isBuffUpdate</i> | The data buffer update flag. |

Returns

The execution status.

19.3.12.4 **enet_status_t** ENET_DRV_CleanupTxBuffDescrip (**enet_dev_if_t** * **enetIfPtr**)

First, store the transmit frame error statistic and PTP timestamp of the transmitted packets. Second, clean up the used transmit buffer descriptors. If the PTP 1588 feature is open, this interface captures the 1588 timestamp. It is called by the transmit interrupt handler.

ENET Peripheral Driver

Parameters

| | |
|------------------|-----------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
|------------------|-----------------------------|

Returns

The execution status.

19.3.12.5 volatile enet_bd_struct_t* ENET_DRV_IncRxBuffDescripIndex (enet_dev_if_t * *enetIfPtr*, volatile enet_bd_struct_t * *curBd*)

Parameters

| | |
|------------------|--|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>curBd</i> | The current buffer descriptor pointer. |

Returns

the increased received buffer descriptor.

19.3.12.6 volatile enet_bd_struct_t* ENET_DRV_IncTxBuffDescripIndex (enet_dev_if_t * *enetIfPtr*, volatile enet_bd_struct_t * *curBd*)

Parameters

| | |
|------------------|--|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>curBd</i> | The current buffer descriptor pointer. |

Returns

the increased transmit buffer descriptor.

19.3.12.7 bool ENET_DRV_RxErrorStats (enet_dev_if_t * *enetIfPtr*, volatile enet_bd_struct_t * *curBd*)

This interface gets the error statistics of the received frame. Because the error information is in the last BD of a frame, this interface should be called when processing the last BD of a frame.

Parameters

| | |
|------------------|--------------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>curBd</i> | The current buffer descriptor. |

Returns

The frame error status.

- True if the frame has an error.
- False if the frame does not have an error.

19.3.12.8 void ENET_DRV_TxErrorStats (enet_dev_if_t * *enetIfPtr*, volatile enet_bd_struct_t * *curBd*)

This interface gets the error statistics of the transmit frame. Because the error information is in the last BD of a frame, this interface should be called when processing the last BD of a frame.

Parameters

| | |
|------------------|--------------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>curBd</i> | The current buffer descriptor. |

19.3.12.9 enet_status_t ENET_DRV_ReceiveData (enet_dev_if_t * *enetIfPtr*)

Parameters

| | |
|------------------|-----------------------------|
| <i>enetIfPtr</i> | The ENET context structure. |
|------------------|-----------------------------|

Returns

The execution status.

19.3.12.10 enet_status_t ENET_DRV_InstallNetIfCall (enet_dev_if_t * *enetIfPtr*, enet_netif_callback_t *function*)

ENET Peripheral Driver

Parameters

| | |
|------------------|--|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>function</i> | The ENET TCP/IP stack net interface callback function. |

Returns

The execution status.

19.3.12.11 **enet_status_t ENET_DRV_SendData (enet_dev_if_t * *enetIfPtr*, uint32_t *dataLen*, uint32_t *bdNumUsed*)**

Parameters

| | |
|------------------|--|
| <i>enetIfPtr</i> | The ENET context structure. |
| <i>dataLen</i> | The frame data length to be transmitted. |
| <i>bdNumUsed</i> | The buffer descriptor need to be used. |

Returns

The execution status.

19.3.12.12 **void ENET_DRV_RxIRQHandler (uint32_t *instance*)**

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | The ENET instance number. |
|-----------------|---------------------------|

19.3.12.13 **void ENET_DRV_TxIRQHandler (uint32_t *instance*)**

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | The ENET instance number. |
|-----------------|---------------------------|

19.3.12.14 void ENET_DRV_CalculateCrc32 (uint8_t * *address*, uint32_t * *crcValue*)

Parameters

| | |
|-----------------|--|
| <i>address</i> | The ENET Mac hardware address. |
| <i>crcValue</i> | The calculated CRC value of the Mac address. |

19.3.12.15 enet_status_t ENET_DRV_AddMulticastGroup (uint32_t *instance*, uint8_t * *address*, uint32_t * *hash*)

Parameters

| | |
|-----------------|--|
| <i>instance</i> | The ENET instance number. |
| <i>address</i> | The multicast group address. |
| <i>hash</i> | The hash value of the multicast group address. |

Returns

The execution status.

19.3.12.16 enet_status_t ENET_DRV_LeaveMulticastGroup (uint32_t *instance*, uint8_t * *address*)

Parameters

| | |
|-----------------|------------------------------|
| <i>instance</i> | The ENET instance number. |
| <i>address</i> | The multicast group address. |

Returns

The execution status.

19.3.12.17 void enet_mac_enqueue_buffer (void ** *queue*, void * *buffer*)

ENET Peripheral Driver

Parameters

| | |
|---------------|--|
| <i>queue</i> | The buffer queue address. |
| <i>buffer</i> | The buffer will add to the buffer queue. |

19.3.12.18 void* enet_mac_dequeue_buffer (void ** *queue*)

Parameters

| | |
|--------------|---------------------------|
| <i>queue</i> | The buffer queue address. |
|--------------|---------------------------|

Returns

The buffer will be dequeued from the buffer queue.

19.3.13 Variable Documentation

19.5 ENET RTCS Adaptor

This chapter describes the programming interface of the ENET RTCS Adaptor.

Chapter 20

External Watchdog Timer (EWM)

20.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the external Watchdog Timer (EWM) block of Kinetis devices.

Modules

- [EWM HAL driver](#)
- [EWM Peripheral Driver](#)

EWM HAL driver

20.2 EWM HAL driver

20.2.1 Overview

The section describes the programming interface of the EWM HAL driver.

Data Structures

- struct [ewm_config_t](#)
Data structure for EWM initialize. [More...](#)

Enumerations

- enum [ewm_status_t](#) {
[kStatus_EWM_Success](#) = 0x0U,
[kStatus_EWM_Fail](#) = 0x01,
[kStatus_EWM_NotInitialized](#) = 0x2U,
[kStatus_EWM_NullArgument](#) = 0x3U }
ewm status return codes.

Functions

- static void [EWM_HAL_Enable](#) (EWM_Type *base)
Enable the EWM.
- static void [EWM_HAL_Disable](#) (EWM_Type *base)
Disable the EWM.
- static bool [EWM_HAL_IsEnable](#) (EWM_Type *base)
Checks whether the EWM is enabled.
- static void [EWM_HAL_SetIntCmd](#) (EWM_Type *base, bool enable)
Enable/Disable EWM interrupt.
- static void [EWM_HAL_SetCmpLowRegValue](#) (EWM_Type *base, uint8_t minServiceCycles)
Set EWM compare low register value.
- static void [EWM_HAL_SetCmpHighRegValue](#) (EWM_Type *base, uint8_t maxServiceCycles)
Set EWM compare high register value.
- static void [EWM_HAL_Refresh](#) (EWM_Type *base)
Service EWM.
- void [EWM_HAL_SetConfig](#) (EWM_Type *base, const [ewm_config_t](#) *ewmConfigPtr)
Config EWM control register.
- void [EWM_HAL_Init](#) (EWM_Type *base)
Restores the EWM module to reset value.

20.2.2 Data Structure Documentation

20.2.2.1 struct ewm_config_t

This structure is used when initializing the EWM.

Data Fields

- bool [ewmEnable](#)
Enable EWM module.
- bool [ewmInEnable](#)
Enable EWM_in input enable.
- bool [ewmInAssertLogic](#)
Set EWM_in signal assertion state.
- bool [intEnable](#)
Enable EWM interrupt enable.
- uint8_t [ewmCmpLowValue](#)
Set EWM compare low register value.
- uint8_t [ewmCmpHighValue](#)
Set EWM compare high register value, the maximum value should be 0xfe otherwise the counter will never expire.

20.2.3 Enumeration Type Documentation

20.2.3.1 enum ewm_status_t

Enumerator

- kStatus_EWM_Success* EWM operation Succeed.
- kStatus_EWM_Fail* EWM operation Failed.
- kStatus_EWM_NotInitialized* EWM is not initialized yet.
- kStatus_EWM_NullArgument* Argument is NULL.

20.2.4 Function Documentation

20.2.4.1 static void EWM_HAL_Enable (EWM_Type * base) [inline], [static]

This function enables the EWM.

Parameters

EWM HAL driver

| | |
|-------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
|-------------|---------------------------------|

20.2.4.2 static void EWM_HAL_Disable (EWM_Type * *base*) [inline], [static]

This function disables the EWM.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
|-------------|---------------------------------|

20.2.4.3 static bool EWM_HAL_IsEnable (EWM_Type * *base*) [inline], [static]

This function checks whether the EWM is enabled.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
|-------------|---------------------------------|

Returns

State of the module

Return values

| | |
|--------------|-----------------------|
| <i>false</i> | means EWM is disabled |
| <i>true</i> | means WODG is enabled |

20.2.4.4 static void EWM_HAL_SetIntCmd (EWM_Type * *base*, bool *enable*) [inline], [static]

This function sets EWM enable/disable.

Parameters

| | |
|---------------|----------------------------------|
| <i>base</i> | The EWM peripheral base address |
| <i>enable</i> | Set EWM interrupt enable/disable |

20.2.4.5 static void EWM_HAL_SetCmpLowRegValue (EWM_Type * *base*, uint8_t *minServiceCycles*) [inline], [static]

This function sets EWM compare low register value and defines the minimum cycles to service EWM, when counter value is greater than or equal to ewm compare low register value, refresh EWM can be successful, and this register is write once, one more write will cause bus fault.

Parameters

| | |
|-------------------------|------------------------------------|
| <i>base</i> | The EWM peripheral base address |
| <i>minServiceCycles</i> | The EWM compare low register value |

20.2.4.6 static void EWM_HAL_SetCmpHighRegValue (EWM_Type * *base*, uint8_t *maxServiceCycles*) [inline], [static]

This function sets EWM compare high register value and defines the maximum cycles to service EWM, when counter value is less than or equal to ewm compare high register value, refresh EWM can be successful, the compare high register value must be greater than compare low register value, and this register is write once, one more write will cause bus fault.

Parameters

| | |
|-------------------------|-------------------------------------|
| <i>base</i> | The EWM peripheral base address |
| <i>maxServiceCycles</i> | The EWM compare high register value |

20.2.4.7 static void EWM_HAL_Refresh (EWM_Type * *base*) [inline], [static]

This function reset EWM counter to zero and the period of writing the frist value and the second value should be within 15 bus cycles.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
|-------------|---------------------------------|

EWM HAL driver

20.2.4.8 void EWM_HAL_SetConfig (EWM_Type * *base*, const ewm_config_t * *ewmConfigPtr*)

This function configures EWM control register, EWM enable bitfeild, EWM ASSIN bitfeild and EWM INPUT enable bitfeild are WRITE ONCE, one more write will cause bus fault.

Parameters

| | |
|---------------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
| <i>ewmConfigPtr</i> | config EWM CTRL register |

20.2.4.9 void EWM_HAL_Init (EWM_Type * *base*)

This function restores the EWM module to reset value.

Parameters

| | |
|-------------|---------------------------------|
| <i>base</i> | The EWM peripheral base address |
|-------------|---------------------------------|

20.3 EWM Peripheral Driver

20.3.1 Overview

The section describes the programming interface of the EWM Peripheral driver. The EWM driver provides an easy way to initialize and configure the EWM.

20.3.2 EWM Initialization

To initialize the EWM module, call the [EWM_DRV_Init\(\)](#) function and pass in the user configuration structure. This function automatically enables the EWM module and clock. After the [EWM_DRV_Init\(\)](#) function is called, the EWM is enabled and its counter is working. Therefore, the [EWM_DRV_Refresh\(\)](#) function should be called before the EWM times out.

This example code shows how to initialize and configure the driver:

```
// Define device configuration.
const ewm_user_config_t init =
{
    .ewmEnable = true, // When reset EWM_out signal is assert, to de-assert the signal EWM must be enabled
    //
    .ewmInAssertionState = kEWMLogicOneAssert, // At reset EWM_in is assert in logic zero, so EWM_in signal
    assertion should be set in logic one, otherwise,
    EWM_out will be assert when servicing EWM counter //
    .ewmInputEnable = true, // Enable the EWM_in signal, so EWM can monitor external circuit //
    .ewmIntEnable = true, // Enable EWM interrupt //
    .ewmCmpLowValue = 0x00, // The compare low register configures the minimum period to service the EWM
    counter //
    .ewmCmpHighValue = 0xfe, // 0xfe is the maximum value for compare high register, because interrupt
    occurs when counter value is greater than compare high register value //
};
```

Initialize EWM. `EWM_DRV_Init(instance, &init);`

20.3.3 EWM Refresh

After the EWM is enabled, the [EWM_DRV_Refresh\(\)](#) function should be called periodically to prevent the EWM from timing out. Otherwise, `EWM_out` is asserted and an EWM interrupt occurs. When `EWM_in` is asserted, servicing EWM causes the `EWM_out` signal to be asserted.

Variables

- `EWM_Type *const g_ewmBase []`
Table of base addresses for EWM instances.
- `const IRQn_Type g_ewmIrqld [EWM_INSTANCE_COUNT]`
Table to save EWM IRQ enumeration numbers defined in the CMSIS header file.

EWM Peripheral Driver

EWM Driver

- `ewm_status_t EWM_DRV_Init` (uint32_t instance, const `ewm_config_t *ConfigPtr`)
Initializes the EWM.
- void `EWM_DRV_Deinit` (uint32_t instance)
Closes the clock for EWM.
- void `EWM_DRV_Refresh` (uint32_t instance)
Refreshes the EWM.
- bool `EWM_DRV_IsRunning` (uint32_t instance)
Gets the EWM running status.
- void `EWM_DRV_SetIntCmd` (uint32_t instance, bool enable)
Enables/disables the EWM interrupt.

20.3.4 Function Documentation

20.3.4.1 `ewm_status_t EWM_DRV_Init (uint32_t instance, const ewm_config_t * ConfigPtr)`

This function initializes the EWM. When called, the EWM runs according to the configuration.

Parameters

| | |
|------------------|---|
| <i>instance</i> | EWM instance ID |
| <i>ConfigPtr</i> | EWM user configure data structure, see #EWM_user_config_t |

Returns

Execution status.

20.3.4.2 `void EWM_DRV_Deinit (uint32_t instance)`

This function sets the run time array to zero and closes the clock.

Parameters

| | |
|-----------------|-----------------|
| <i>instance</i> | EWM instance ID |
|-----------------|-----------------|

20.3.4.3 `void EWM_DRV_Refresh (uint32_t instance)`

This function feeds the EWM. It sets the EWM timer count to zero and should be called before the EWM timer times out.

Parameters

| | |
|-----------------|-----------------|
| <i>instance</i> | EWM instance ID |
|-----------------|-----------------|

20.3.4.4 bool EWM_DRV_IsRunning (uint32_t *instance*)

This function gets the EWM running status.

Parameters

| | |
|-----------------|-----------------|
| <i>instance</i> | EWM instance ID |
|-----------------|-----------------|

Returns

EWM running status. False means not running. True means running

20.3.4.5 void EWM_DRV_SetIntCmd (uint32_t *instance*, bool *enable*)

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | EWM instance ID. |
| <i>enable</i> | EWM interrupt enable/disable. |

20.3.5 Variable Documentation

20.3.5.1 EWM_Type* const g_ewmBase[]

20.3.5.2 const IRQn_Type g_ewmIrqId[EWM_INSTANCE_COUNT]

Chapter 21

Controller Area Network (FlexCAN)

21.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the FlexCAN Controller Area Network (FlexCAN) block of Kinetis devices.

Modules

- [FlexCAN Driver](#)
- [FlexCAN HAL driver](#)

FlexCAN Driver

21.2 FlexCAN Driver

21.2.1 Overview

This section describes the programming interface of the FlexCAN Peripheral driver.

21.2.2 FlexCAN Overview

The FlexCAN (flexible controller area network) module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification. The FlexCAN module supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. The CAN Protocol Engine (PE) sub-module manages the serial communication on the CAN bus by requesting RAM access for receiving and transmitting message frames, validating received messages, and performing error handling.

21.2.3 FlexCAN Initialization

To initialize the FlexCAN driver, call the `FLEXCAN_DRV_Init()` function and pass the instance number of the FlexCAN you want to use. For example, to use FlexCAN0, pass a value of 0 to the `flexcan_init` function. In addition, you should also pass a user configuration structure `flexcan_user_config_t`, as shown here:

```
// FlexCAN configuration structure for user
typedef struct FLEXCANUserConfig {
    uint32_t max_num_mb;
    flexcan_rx_fifo_id_filter_num_t num_id_filters;
    bool is_rx_fifo_needed;
} flexcan_user_config_t;
```

Typically, the user configures the `flexcan_user_config_t` instantiation as 16 message buffers, 8 RX FIFO ID filters and set to true when RX FIFO is needed. This is a code example to set up a FlexCAN configuration instantiation:

```
flexcan_config_t flexcan1_data;

flexcan1_data.max_num_mb = 16;
flexcan1_data.num_id_filters = kFlexCanRxFifoIDFilters_8;
flexcan1_data.is_rx_fifo_needed = true;
```

21.2.4 FlexCAN Module timing

FlexCAN bit rate is derived from the serial clock, which is generated by dividing the PE clock by the programmed `PRESDIV` value. Each serial clock period is also called a time quantum. The FlexCAN bit-rate is defined as the `Sclock` divided by the number of time quanta, where time quanta are further broken down segments within the bit time (time to transmit and sample a bit). This list shows the CAN

bit-rates that are supported in the FlexCAN driver. 1 Mbytes/s 750 Kbytes/s 500 Kbytes/s 250 Kbytes/s 125 Kbytes/s

The FlexCAN module supports several different ways to set up the bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

To calculate the CAN bit timing parameters, use the method outlined in the Application Note AN1798, section 4.1. A maximum time for PROP_SEG is used, the remaining TQ is split equally between PSEG1 and PSEG2, provided PSEG2 ≥ 2 . RJW is set to the minimum of 4 or to the PSEG1.

21.2.5 FlexCAN Transfers

To transmit a FlexCAN frame, the CPU must prepare a message buffer for transmission by calling the [FLEXCAN_DRV_Send\(\)](#) function. To receive the FlexCAN frames into a message buffer, the CPU must also prepare it for reception by first setting up the receive mask by calling [FLEXCAN_DRV_SetMaskType\(\)](#), [FLEXCAN_DRV_SetRxFifoGlobalMask\(\)](#), [FLEXCAN_DRV_SetRxMbGlobalMask\(\)](#) and [FLEXCAN_DRV_SetRxIndividualMask\(\)](#) functions. Then configure the RX buffers by calling either [FLEXCAN_DRV_ConfigRxMb\(\)](#) or [FLEXCAN_DRV_ConfigRxFifo\(\)](#) functions depending on the mode of reception. Finally, call [FLEXCAN_DRV_RxMessageBuffer\(\)](#) or [FLEXCAN_DRV_RxFifo](#) functions depending on the mode of reception. The FlexCAN uses only the interrupt-driven process to transfer data.

Data Structures

- struct [flexcan_state_t](#)
Internal driver state information. [More...](#)
- struct [flexcan_data_info_t](#)
FlexCAN data info from user. [More...](#)
- struct [flexcan_user_config_t](#)
FlexCAN configuration. [More...](#)

Functions

- void [FLEXCAN_DRV_IRQHandler](#) (uint8_t instance)
Interrupt handler for a FlexCAN instance.
- [flexcan_status_t FLEXCAN_DRV_GetTransmitStatus](#) (uint32_t instance)
Returns whether the previous FLEXCAN transmit has finished.
- [flexcan_status_t FLEXCAN_DRV_GetReceiveStatus](#) (uint32_t instance)
Returns whether the previous FLEXCAN receive is complete.

Variables

- CAN_Type *const [g_flexcanBase](#) []
Table of base addresses for FlexCAN instances.

FlexCAN Driver

- const IRQn_Type [g_flexcanRxWarningIrqId](#) []
Table to save RX Warning IRQ numbers for FlexCAN instances.
- const IRQn_Type [g_flexcanTxWarningIrqId](#) []
Table to save TX Warning IRQ numbers for FlexCAN instances.
- const IRQn_Type [g_flexcanWakeUpIrqId](#) []
Table to save wakeup IRQ numbers for FlexCAN instances.
- const IRQn_Type [g_flexcanErrorIrqId](#) []
Table to save error IRQ numbers for FlexCAN instances.
- const IRQn_Type [g_flexcanBusOffIrqId](#) []
Table to save Bus off IRQ numbers for FlexCAN instances.
- const IRQn_Type [g_flexcanOredMessageBufferIrqId](#) []
Table to save message buffer IRQ numbers for FlexCAN instances.

Bit rate

- [flexcan_status_t FLEXCAN_DRV_SetBitrate](#) (uint8_t instance, [flexcan_time_segment_t](#) *bitrate)
Sets the FlexCAN bit rate.
- [flexcan_status_t FLEXCAN_DRV_GetBitrate](#) (uint8_t instance, [flexcan_time_segment_t](#) *bitrate)
Gets the FlexCAN bit rate.

Global mask

- void [FLEXCAN_DRV_SetRxMaskType](#) (uint8_t instance, [flexcan_rx_mask_type_t](#) type)
Sets the RX masking type.
- [flexcan_status_t FLEXCAN_DRV_SetRxFifoGlobalMask](#) (uint8_t instance, [flexcan_msgbuff_id_type_t](#) id_type, uint32_t mask)
Sets the FlexCAN RX FIFO global standard or extended mask.
- [flexcan_status_t FLEXCAN_DRV_SetRxMbGlobalMask](#) (uint8_t instance, [flexcan_msgbuff_id_type_t](#) id_type, uint32_t mask)
Sets the FlexCAN RX MB global standard or extended mask.
- [flexcan_status_t FLEXCAN_DRV_SetRxIndividualMask](#) (uint8_t instance, [flexcan_msgbuff_id_type_t](#) id_type, uint32_t mb_idx, uint32_t mask)
Sets the FlexCAN RX individual standard or extended mask.

Initialization and Shutdown

- [flexcan_status_t FLEXCAN_DRV_Init](#) (uint32_t instance, [flexcan_state_t](#) *state, const [flexcan_user_config_t](#) *data)
Initializes the FlexCAN peripheral.
- uint32_t [FLEXCAN_DRV_Deinit](#) (uint8_t instance)
Shuts down a FlexCAN instance.

Send configuration

- `flexcan_status_t FLEXCAN_DRV_ConfigTxMb` (uint8_t instance, uint32_t mb_idx, `flexcan_data_info_t *tx_info`, uint32_t msg_id)
FlexCAN transmit message buffer field configuration.
- `flexcan_status_t FLEXCAN_DRV_SendBlocking` (uint8_t instance, uint32_t mb_idx, `flexcan_data_info_t *tx_info`, uint32_t msg_id, uint8_t *mb_data, uint32_t timeout_ms)
Sends FlexCAN messages.
- `flexcan_status_t FLEXCAN_DRV_Send` (uint8_t instance, uint32_t mb_idx, `flexcan_data_info_t *tx_info`, uint32_t msg_id, uint8_t *mb_data)
Sends FlexCAN messages.

Receive configuration

- `flexcan_status_t FLEXCAN_DRV_ConfigRxMb` (uint8_t instance, uint32_t mb_idx, `flexcan_data_info_t *rx_info`, uint32_t msg_id)
FlexCAN receive message buffer field configuration.
- `flexcan_status_t FLEXCAN_DRV_ConfigRxFifo` (uint8_t instance, `flexcan_rx_fifo_id_element_format_t id_format`, `flexcan_id_table_t *id_filter_table`)
FlexCAN RX FIFO field configuration.
- `flexcan_status_t FLEXCAN_DRV_RxMessageBufferBlocking` (uint8_t instance, uint32_t mb_idx, `flexcan_msgbuff_t *data`, uint32_t timeout_ms)
FlexCAN is waiting to receive data from the message buffer.
- `flexcan_status_t FLEXCAN_DRV_RxMessageBuffer` (uint8_t instance, uint32_t mb_idx, `flexcan_msgbuff_t *data`)
FlexCAN is waiting to receive data from the message buffer.
- `flexcan_status_t FLEXCAN_DRV_RxFifoBlocking` (uint8_t instance, `flexcan_msgbuff_t *data`, uint32_t timeout_ms)
FlexCAN is waiting to receive data from the message FIFO.
- `flexcan_status_t FLEXCAN_DRV_RxFifo` (uint8_t instance, `flexcan_msgbuff_t *data`)
FlexCAN is waiting to receive data from the message FIFO.

21.2.6 Data Structure Documentation

21.2.6.1 struct flexcan_state_t

Note

The contents of this structure are internal to the driver and should not be modified by users. Also, contents of the structure are subject to change in future releases.

Data Fields

- `flexcan_msgbuff_t * fifo_message`
The FlexCAN receive FIFO data.
- `flexcan_msgbuff_t * mb_message`

FlexCAN Driver

- *The FlexCAN receive MB data.*
- volatile uint32_t [rx_mb_idx](#)
Index of the message buffer for receiving.
- volatile uint32_t [tx_mb_idx](#)
Index of the message buffer for transmitting.
- [semaphore_t txIrqSync](#)
Used to wait for ISR to complete its TX business.
- [semaphore_t rxIrqSync](#)
Used to wait for ISR to complete its RX business.
- volatile bool [isTxBusy](#)
True if there is an active transmit.
- volatile bool [isRxBusy](#)
True if there is an active receive.
- volatile bool [isTxBlocking](#)
True if transmit is blocking transaction.
- volatile bool [isRxBlocking](#)
True if receive is blocking transaction.

21.2.6.1.0.102 Field Documentation

21.2.6.1.0.102.1 [semaphore_t flexcan_state_t::txIrqSync](#)

21.2.6.1.0.102.2 [semaphore_t flexcan_state_t::rxIrqSync](#)

21.2.6.1.0.102.3 [volatile bool flexcan_state_t::isTxBusy](#)

21.2.6.1.0.102.4 [volatile bool flexcan_state_t::isRxBusy](#)

21.2.6.1.0.102.5 [volatile bool flexcan_state_t::isTxBlocking](#)

21.2.6.1.0.102.6 [volatile bool flexcan_state_t::isRxBlocking](#)

21.2.6.2 struct flexcan_data_info_t

Data Fields

- [flexcan_msgbuff_id_type_t msg_id_type](#)
Type of message ID (standard or extended)
- uint32_t [data_length](#)
Length of Data in Bytes.

21.2.6.3 struct flexcan_user_config_t

Data Fields

- uint32_t [max_num_mb](#)
The maximum number of Message Buffers.
- [flexcan_rx_fifo_id_filter_num_t num_id_filters](#)
The number of RX FIFO ID filters needed.
- bool [is_rx_fifo_needed](#)

- 1 if needed; 0 if not.*
 - [flexcan_operation_modes_t flexcanMode](#)
User configurable FlexCAN operation modes.

21.2.6.3.0.103 Field Documentation

21.2.6.3.0.103.1 bool flexcan_user_config_t::is_rx_fifo_needed

This controls whether the Rx FIFO feature is enabled or not.

21.2.7 Function Documentation

21.2.7.1 flexcan_status_t FLEXCAN_DRV_SetBitrate (uint8_t *instance*, flexcan_time_segment_t * *bitrate*)

Parameters

| | |
|-----------------|---|
| <i>instance</i> | A FlexCAN instance number |
| <i>bitrate</i> | A pointer to the FlexCAN bit rate settings. |

Returns

0 if successful; non-zero failed

21.2.7.2 flexcan_status_t FLEXCAN_DRV_GetBitrate (uint8_t *instance*, flexcan_time_segment_t * *bitrate*)

Parameters

| | |
|-----------------|---|
| <i>instance</i> | A FlexCAN instance number |
| <i>bitrate</i> | A pointer to a variable for returning the FlexCAN bit rate settings |

Returns

0 if successful; non-zero failed

21.2.7.3 void FLEXCAN_DRV_SetRxMaskType (uint8_t *instance*, flexcan_rx_mask_type_t *type*)

FlexCAN Driver

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>type</i> | The FlexCAN RX mask type |

21.2.7.4 flexcan_status_t FLEXCAN_DRV_SetRxFifoGlobalMask (uint8_t *instance*, flexcan_msgbuff_id_type_t *id_type*, uint32_t *mask*)

Parameters

| | |
|-----------------|----------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>id_type</i> | Standard ID or extended ID |
| <i>mask</i> | Mask value |

Returns

0 if successful; non-zero failed

21.2.7.5 flexcan_status_t FLEXCAN_DRV_SetRxMbGlobalMask (uint8_t *instance*, flexcan_msgbuff_id_type_t *id_type*, uint32_t *mask*)

Parameters

| | |
|-----------------|----------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>id_type</i> | Standard ID or extended ID |
| <i>mask</i> | Mask value |

Returns

0 if successful; non-zero failed

21.2.7.6 flexcan_status_t FLEXCAN_DRV_SetRxIndividualMask (uint8_t *instance*, flexcan_msgbuff_id_type_t *id_type*, uint32_t *mb_idx*, uint32_t *mask*)

Parameters

| | |
|-----------------|---------------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>id_type</i> | A standard ID or an extended ID |
| <i>mb_idx</i> | Index of the message buffer |
| <i>mask</i> | Mask value |

Returns

0 if successful; non-zero failed.

21.2.7.7 flexcan_status_t FLEXCAN_DRV_Init (uint32_t *instance*, flexcan_state_t * *state*, const flexcan_user_config_t * *data*)

This function initializes

Parameters

| | |
|-----------------|--|
| <i>instance</i> | A FlexCAN instance number |
| <i>state</i> | Pointer to the FlexCAN driver state structure. |
| <i>data</i> | The FlexCAN platform data |

Returns

0 if successful; non-zero failed

21.2.7.8 uint32_t FLEXCAN_DRV_Deinit (uint8_t *instance*)

Parameters

| | |
|-----------------|---------------------------|
| <i>instance</i> | A FlexCAN instance number |
|-----------------|---------------------------|

Returns

0 if successful; non-zero failed

21.2.7.9 flexcan_status_t FLEXCAN_DRV_ConfigTxMb (uint8_t *instance*, uint32_t *mb_idx*, flexcan_data_info_t * *tx_info*, uint32_t *msg_id*)

FlexCAN Driver

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>tx_info</i> | Data info |
| <i>msg_id</i> | ID of the message to transmit |

Returns

0 if successful; non-zero failed

21.2.7.10 `flexcan_status_t FLEXCAN_DRV_SendBlocking (uint8_t instance, uint32_t mb_idx, flexcan_data_info_t * tx_info, uint32_t msg_id, uint8_t * mb_data, uint32_t timeout_ms)`

Parameters

| | |
|-------------------|---|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>tx_info</i> | Data info |
| <i>msg_id</i> | ID of the message to transmit |
| <i>mb_data</i> | Bytes of the FlexCAN message |
| <i>timeout_ms</i> | A timeout for the transfer in milliseconds. |

Returns

0 if successful; non-zero failed

21.2.7.11 `flexcan_status_t FLEXCAN_DRV_Send (uint8_t instance, uint32_t mb_idx, flexcan_data_info_t * tx_info, uint32_t msg_id, uint8_t * mb_data)`

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>tx_info</i> | Data info |
| <i>msg_id</i> | ID of the message to transmit |
| <i>mb_data</i> | Bytes of the FlexCAN message. |

Returns

0 if successful; non-zero failed

21.2.7.12 flexcan_status_t FLEXCAN_DRV_ConfigRxMb (uint8_t *instance*, uint32_t *mb_idx*, flexcan_data_info_t * *rx_info*, uint32_t *msg_id*)

Parameters

| | |
|-----------------|-------------------------------|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>rx_info</i> | Data info |
| <i>msg_id</i> | ID of the message to transmit |

Returns

0 if successful; non-zero failed

21.2.7.13 flexcan_status_t FLEXCAN_DRV_ConfigRxFifo (uint8_t *instance*, flexcan_rx_fifo_id_element_format_t *id_format*, flexcan_id_table_t * *id_filter_table*)

Parameters

| | |
|------------------|--|
| <i>instance</i> | A FlexCAN instance number |
| <i>id_format</i> | The format of the RX FIFO ID Filter Table Elements |

FlexCAN Driver

| | |
|------------------------|--|
| <i>id_filter_table</i> | The ID filter table elements which contain RTR bit, IDE bit, and RX message ID |
|------------------------|--|

Returns

0 if successful; non-zero failed.

21.2.7.14 flexcan_status_t FLEXCAN_DRV_RxMessageBufferBlocking (uint8_t *instance*, uint32_t *mb_idx*, flexcan_msgbuff_t * *data*, uint32_t *timeout_ms*)

Parameters

| | |
|-------------------|---|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>data</i> | The FlexCAN receive message buffer data. |
| <i>timeout_ms</i> | A timeout for the transfer in milliseconds. |

Returns

0 if successful; non-zero failed

21.2.7.15 flexcan_status_t FLEXCAN_DRV_RxMessageBuffer (uint8_t *instance*, uint32_t *mb_idx*, flexcan_msgbuff_t * *data*)

Parameters

| | |
|-----------------|--|
| <i>instance</i> | A FlexCAN instance number |
| <i>mb_idx</i> | Index of the message buffer |
| <i>data</i> | The FlexCAN receive message buffer data. |

Returns

0 if successful; non-zero failed

21.2.7.16 flexcan_status_t FLEXCAN_DRV_RxFifoBlocking (uint8_t *instance*, flexcan_msgbuff_t * *data*, uint32_t *timeout_ms*)

Parameters

| | |
|-------------------|---|
| <i>instance</i> | A FlexCAN instance number |
| <i>data</i> | The FlexCAN receive message buffer data. |
| <i>timeout_ms</i> | A timeout for the transfer in milliseconds. |

Returns

0 if successful; non-zero failed

21.2.7.17 flexcan_status_t FLEXCAN_DRV_RxFifo (uint8_t *instance*, flexcan_msgbuff_t * *data*)

Parameters

| | |
|-----------------|--|
| <i>instance</i> | A FlexCAN instance number |
| <i>data</i> | The FlexCAN receive message buffer data. |

Returns

0 if successful; non-zero failed

21.2.7.18 void FLEXCAN_DRV_IRQHandler (uint8_t *instance*)

Parameters

| | |
|-----------------|------------------------------|
| <i>instance</i> | The FlexCAN instance number. |
|-----------------|------------------------------|

21.2.7.19 flexcan_status_t FLEXCAN_DRV_GetTransmitStatus (uint32_t *instance*)

When performing an async transmit, call this function to ascertain the state of the current transmission: in progress (or busy) or complete (success).

Parameters

FlexCAN Driver

| | |
|-----------------|----------------------------------|
| <i>instance</i> | The FLEXCAN module base address. |
|-----------------|----------------------------------|

Returns

The transmit status.

Return values

| | |
|--------------------------------|--|
| <i>kStatus_FLEXCAN_Success</i> | The transmit has completed successfully. |
| <i>kStatus_FLEXCAN_Tx-Busy</i> | The transmit is still in progress. |

21.2.7.20 flexcan_status_t FLEXCAN_DRV_GetReceiveStatus (uint32_t instance)

When performing an async receive, call this function to find out the state of the current receive progress: in progress (or busy) or complete (success).

Parameters

| | |
|------------------------|---|
| <i>instance</i> | The FLEXCAN module base address. |
| <i>bytes-Remaining</i> | A pointer to a value that is filled in with the number of bytes which still need to be received in the active transfer. |

Returns

The receive status.

Return values

| | |
|--------------------------------|---|
| <i>kStatus_FLEXCAN_Success</i> | The receive has completed successfully. |
| <i>kStatus_FLEXCAN_Rx-Busy</i> | The receive is still in progress. |

21.2.8 Variable Documentation

21.2.8.1 `CAN_Type* const g_flexcanBase[]`

```

FlexCAN receive FIFO filters number.

FlexCAN HAL driver

- enum `flexcan_rx_mask_type_t` {
`kFlexCanRxMaskGlobal`,
`kFlexCanRxMaskIndividual` }
FlexCAN receive mask type.
- enum `flexcan_msgbuff_id_type_t` {
`kFlexCanMsgIdStd`,
`kFlexCanMsgIdExt` }
FlexCAN Message Buffer ID type.
- enum `flexcan_clk_source_t` {
`kFlexCanClkSourceOsc`,
`kFlexCanClkSourceIpbuss` }
FlexCAN clock source.
- enum `flexcan_int_type_t` {
`kFlexCanIntRxwarning` = CAN_CTRL1_RWRNMSK_MASK,
`kFlexCanIntTxwarning` = CAN_CTRL1_TWRNMSK_MASK,
`kFlexCanIntErr` = CAN_CTRL1_ERRMSK_MASK,
`kFlexCanIntBusoff` = CAN_CTRL1_BOFFMSK_MASK,
`kFlexCanIntWakeup` = CAN_MCR_WAKMSK_MASK }
FlexCAN error interrupt types.

Configuration

- `flexcan_status_t FLEXCAN_HAL_Enable` (CAN_Type *base)
Enables FlexCAN controller.
- `flexcan_status_t FLEXCAN_HAL_Disable` (CAN_Type *base)
Disables FlexCAN controller.
- `flexcan_status_t FLEXCAN_HAL_SelectClock` (CAN_Type *base, `flexcan_clk_source_t` clk)
Selects the clock source for FlexCAN.
- static bool `FLEXCAN_HAL_GetClock` (CAN_Type *base)
Reads the clock source for FlexCAN Protocol Engine (PE).
- `flexcan_status_t FLEXCAN_HAL_Init` (CAN_Type *base)
Initializes the FlexCAN controller.
- void `FLEXCAN_HAL_SetTimeSegments` (CAN_Type *base, `flexcan_time_segment_t` *timeSeg)
Sets the FlexCAN time segments for setting up bit rate.
- void `FLEXCAN_HAL_GetTimeSegments` (CAN_Type *base, `flexcan_time_segment_t` *timeSeg)
Gets the FlexCAN time segments to calculate the bit rate.
- void `FLEXCAN_HAL_ExitFreezeMode` (CAN_Type *base)
Unfreezes the FlexCAN module.
- void `FLEXCAN_HAL_EnterFreezeMode` (CAN_Type *base)
Freezes the FlexCAN module.
- `flexcan_status_t FLEXCAN_HAL_SetOperationMode` (CAN_Type *base, `flexcan_operation_modes_t` mode)
Sets operation mode.
- `flexcan_status_t FLEXCAN_HAL_ExitOperationMode` (CAN_Type *base, `flexcan_operation_modes_t` mode)
Exits operation mode.

Data transfer

- [flexcan_status_t FLEXCAN_HAL_SetTxMsgBuff](#) (CAN_Type *base, uint32_t msgBuffIdx, flexcan_msgbuff_code_status_t *cs, uint32_t msgId, uint8_t *msgData)
Sets the FlexCAN message buffer fields for transmitting.
- [flexcan_status_t FLEXCAN_HAL_SetRxMsgBuff](#) (CAN_Type *base, uint32_t msgBuffIdx, flexcan_msgbuff_code_status_t *cs, uint32_t msgId)
Sets the FlexCAN message buffer fields for receiving.
- [flexcan_status_t FLEXCAN_HAL_GetMsgBuff](#) (CAN_Type *base, uint32_t msgBuffIdx, flexcan_msgbuff_t *msgBuff)
Gets the FlexCAN message buffer fields.
- [flexcan_status_t FLEXCAN_HAL_LockRxMsgBuff](#) (CAN_Type *base, uint32_t msgBuffIdx)
Locks the FlexCAN receive message buffer.
- [static uint32_t FLEXCAN_HAL_UnlockRxMsgBuff](#) (CAN_Type *base)
Unlocks the FlexCAN receive message buffer.
- [void FLEXCAN_HAL_EnableRxFifo](#) (CAN_Type *base, uint32_t numOfFilters)
Enables the receive FIFO.
- [void FLEXCAN_HAL_DisableRxFifo](#) (CAN_Type *base)
Disables the receive FIFO.
- [void FLEXCAN_HAL_SetRxFifoFilterNum](#) (CAN_Type *base, uint32_t number)
Sets the number of the receive FIFO filters.
- [void FLEXCAN_HAL_SetMaxMsgBuffNum](#) (CAN_Type *base, uint32_t maxMsgBuffNum)
Sets the number of the last message buffer.
- [flexcan_status_t FLEXCAN_HAL_SetRxFifoFilter](#) (CAN_Type *base, flexcan_rx_fifo_id_element_format_t idFormat, flexcan_id_table_t *idFilterTable)
Sets the FlexCAN receive FIFO fields.
- [flexcan_status_t FLEXCAN_HAL_ReadRxFifo](#) (CAN_Type *base, flexcan_msgbuff_t *rxFifo)
Gets the FlexCAN receive FIFO data.

Interrupts

- [flexcan_status_t FLEXCAN_HAL_SetMsgBuffIntCmd](#) (CAN_Type *base, uint32_t msgBuffIdx, bool enable)
Enables/disables the FlexCAN message buffer interrupt.
- [void FLEXCAN_HAL_SetErrIntCmd](#) (CAN_Type *base, flexcan_int_type_t errType, bool enable)
Enables the error interrupt of the FlexCAN module.

Status

- [static uint32_t FLEXCAN_HAL_GetFreezeAck](#) (CAN_Type *base)
Gets the value of the FlexCAN freeze ACK.
- [uint8_t FLEXCAN_HAL_GetMsgBuffIntStatusFlag](#) (CAN_Type *base, uint32_t msgBuffIdx)
Gets the individual FlexCAN MB interrupt flag.
- [static uint32_t FLEXCAN_HAL_GetAllMsgBuffIntStatusFlag](#) (CAN_Type *base)
Gets all FlexCAN message buffer interrupt flags.
- [static void FLEXCAN_HAL_ClearMsgBuffIntStatusFlag](#) (CAN_Type *base, uint32_t flag)
Clears the interrupt flag of the message buffers.
- [void FLEXCAN_HAL_GetErrCounter](#) (CAN_Type *base, flexcan_buserr_counter_t *errCount)

FlexCAN HAL driver

- Gets the transmit error counter and receives the error counter.*

 - static uint32_t [FLEXCAN_HAL_GetErrStatus](#) (CAN_Type *base)

Gets an error and status.
- void [FLEXCAN_HAL_ClearErrIntStatusFlag](#) (CAN_Type *base)

Clears all other interrupts in ERRSTAT register (Error, Busoff, and Wakeup).

Mask

- void [FLEXCAN_HAL_SetRxMaskType](#) (CAN_Type *base, flexcan_rx_mask_type_t type)

Sets the receive masking type.
- void [FLEXCAN_HAL_SetRxFifoGlobalStdMask](#) (CAN_Type *base, uint32_t stdMask)

Sets the FlexCAN receive FIFO global standard mask.
- void [FLEXCAN_HAL_SetRxFifoGlobalExtMask](#) (CAN_Type *base, uint32_t extMask)

Sets the FlexCAN receive FIFO global extended mask.
- flexcan_status_t [FLEXCAN_HAL_SetRxIndividualStdMask](#) (CAN_Type *base, uint32_t msg-BuffIdx, uint32_t stdMask)

Sets the FlexCAN receive individual standard mask for ID filtering in the receive MBs and the receive FIFO.
- flexcan_status_t [FLEXCAN_HAL_SetRxIndividualExtMask](#) (CAN_Type *base, uint32_t msg-BuffIdx, uint32_t extMask)

Sets the FlexCAN receive individual extended mask for ID filtering in the receive Message Buffers and the receive FIFO.
- void [FLEXCAN_HAL_SetRxMsgBuffGlobalStdMask](#) (CAN_Type *base, uint32_t stdMask)

Sets the FlexCAN receive Message Buffer global standard mask.
- void [FLEXCAN_HAL_SetRxMsgBuff14StdMask](#) (CAN_Type *base, uint32_t stdMask)

Sets the FlexCAN receive Message Buffer BUF14 standard mask.
- void [FLEXCAN_HAL_SetRxMsgBuff15StdMask](#) (CAN_Type *base, uint32_t stdMask)

Sets the FlexCAN receive Message Buffer BUF15 standard mask.
- void [FLEXCAN_HAL_SetRxMsgBuffGlobalExtMask](#) (CAN_Type *base, uint32_t extMask)

Sets the FlexCAN receive Message Buffer global extended mask.
- void [FLEXCAN_HAL_SetRxMsgBuff14ExtMask](#) (CAN_Type *base, uint32_t extMask)

Sets the FlexCAN receive Message Buffer BUF14 extended mask.
- void [FLEXCAN_HAL_SetRxMsgBuff15ExtMask](#) (CAN_Type *base, uint32_t extMask)

Sets the FlexCAN receive MB BUF15 extended mask.
- static uint32_t [FLEXCAN_HAL_GetRxFifoHitIdAcceptanceFilter](#) (CAN_Type *base)

Gets the FlexCAN ID acceptance filter hit indicator on receive FIFO.

21.3.2 Data Structure Documentation

21.3.2.1 struct flexcan_id_table_t

Data Fields

- bool [isRemoteFrame](#)
Remote frame.
- bool [isExtendedFrame](#)
Extended frame.
- uint32_t * [idFilter](#)

Receive FIFO ID filter elements.

21.3.2.2 struct flexcan_buserr_counter_t

Data Fields

- uint16_t `txerr`
Transmit error counter.
- uint16_t `rxerr`
Receive error counter.

21.3.2.3 struct flexcan_msgbuff_code_status_t

Data Fields

- uint32_t `code`
MB code for transmit or receive buffers.
- flexcan_msgbuff_id_type_t `msgIdType`
Type of message ID (standard or extended)
- uint32_t `dataLen`
Length of Data in Bytes.

21.3.2.3.0.104 Field Documentation

21.3.2.3.0.104.1 uint32_t flexcan_msgbuff_code_status_t::code

Defined by flexcan_mb_code_rx_t and flexcan_mb_code_tx_t

21.3.2.4 struct flexcan_msgbuff_t

Data Fields

- uint32_t `cs`
Code and Status.
- uint32_t `msgId`
Message Buffer ID.
- uint8_t `data` [`kFlexCanMessageSize`]
Bytes of the FlexCAN message.

21.3.2.5 struct flexcan_time_segment_t

Data Fields

- uint32_t `propSeg`
Propagation segment.
- uint32_t `phaseSeg1`
Phase segment 1.

FlexCAN HAL driver

- uint32_t [phaseSeg2](#)
Phase segment 2.
- uint32_t [preDivider](#)
Clock pre divider.
- uint32_t [rJumpwidth](#)
Resync jump width.

21.3.3 Enumeration Type Documentation

21.3.3.1 enum _flexcan_constants

Enumerator

kFlexCanMessageSize FlexCAN message buffer data size in bytes.

21.3.3.2 enum _flexcan_err_status

Enumerator

kFlexCanRxWrn Reached warning level for RX errors.

kFlexCanTxWrn Reached warning level for TX errors.

kFlexCanStfErr Stuffing Error.

kFlexCanFrmErr Form Error.

kFlexCanCrcErr Cyclic Redundancy Check Error.

kFlexCanAckErr Received no ACK on transmission.

kFlexCanBit0Err Unable to send dominant bit.

kFlexCanBit1Err Unable to send recessive bit.

21.3.3.3 enum flexcan_operation_modes_t

Enumerator

kFlexCanNormalMode Normal mode or user mode.

kFlexCanListenOnlyMode Listen-only mode.

kFlexCanLoopBackMode Loop-back mode.

kFlexCanFreezeMode Freeze mode.

kFlexCanDisableMode Module disable mode.

21.3.3.4 enum flexcan_msgbuff_code_rx_t

Enumerator

kFlexCanRXInactive MB is not active.

kFlexCanRXFull MB is full.

kFlexCanRXEmpty MB is active and empty.

kFlexCanRXOverrun MB is overwritten into a full buffer.

kFlexCanRXBusy FlexCAN is updating the contents of the MB.

kFlexCanRXRanswer The CPU must not access the MB. A frame was configured to recognize a Remote Request Frame

kFlexCanRXNotUsed and transmit a Response Frame in return. Not used

21.3.3.5 enum flexcan_msgbuff_code_tx_t

Enumerator

kFlexCanTXInactive MB is not active.

kFlexCanTXAbort MB is aborted.

kFlexCanTXData MB is a transmit data frame(MB RTR must be 0).

kFlexCanTXRemote MB is a transmit remote request frame (MB RTR must be 1).

kFlexCanTXTanswer MB is a transmit response request frame from.

kFlexCanTXNotUsed an incoming remote request frame. Not used

21.3.3.6 enum flexcan_msgbuff_transmission_type_t

Enumerator

kFlexCanMBStatusTypeTX Transmit MB.

kFlexCanMBStatusTypeTXRemote Transmit remote request MB.

kFlexCanMBStatusTypeRX Receive MB.

kFlexCanMBStatusTypeRXRemote Receive remote request MB.

kFlexCanMBStatusTypeRXTXRemote FlexCAN remote frame receives remote request and. transmits MB.

21.3.3.7 enum flexcan_rx_fifo_id_element_format_t

Enumerator

kFlexCanRxFifoIdElementFormatA One full ID (standard and extended) per ID Filter Table.

kFlexCanRxFifoIdElementFormatB element. Two full standard IDs or two partial 14-bit (standard and

kFlexCanRxFifoIdElementFormatC extended) IDs per ID Filter Table element. Four partial 8-bit Standard IDs per ID Filter Table

kFlexCanRxFifoIdElementFormatD element. All frames rejected.

FlexCAN HAL driver

21.3.3.8 enum flexcan_rx_fifo_id_filter_num_t

Enumerator

| | |
|------------------------------------|---------------------------|
| <i>kFlexCanRxFifoIDFilters_8</i> | 8 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_16</i> | 16 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_24</i> | 24 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_32</i> | 32 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_40</i> | 40 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_48</i> | 48 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_56</i> | 56 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_64</i> | 64 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_72</i> | 72 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_80</i> | 80 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_88</i> | 88 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_96</i> | 96 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_104</i> | 104 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_112</i> | 112 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_120</i> | 120 receive FIFO Filters. |
| <i>kFlexCanRxFifoIDFilters_128</i> | 128 receive FIFO Filters. |

21.3.3.9 enum flexcan_rx_mask_type_t

Enumerator

| | |
|---------------------------------|--------------------------|
| <i>kFlexCanRxMaskGlobal</i> | Receive global mask. |
| <i>kFlexCanRxMaskIndividual</i> | Receive individual mask. |

21.3.3.10 enum flexcan_msgbuff_id_type_t

Enumerator

| | |
|-------------------------|--------------|
| <i>kFlexCanMsgIdStd</i> | Standard ID. |
| <i>kFlexCanMsgIdExt</i> | Extended ID. |

21.3.3.11 enum flexcan_clk_source_t

Enumerator

| | |
|------------------------------|-------------------|
| <i>kFlexCanClkSourceOsc</i> | Oscillator clock. |
| <i>kFlexCanClkSourceIpbu</i> | Peripheral clock. |

21.3.3.12 enum flexcan_int_type_t

Enumerator

- kFlexCanIntRxwarning* Receive warning interrupt.
- kFlexCanIntTxwarning* Transmit warning interrupt.
- kFlexCanIntErr* Error interrupt.
- kFlexCanIntBusoff* Bus off interrupt.
- kFlexCanIntWakeup* Wake up interrupt.

21.3.4 Function Documentation

21.3.4.1 flexcan_status_t FLEXCAN_HAL_Enable (CAN_Type * base)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

0 if successful; non-zero failed

21.3.4.2 flexcan_status_t FLEXCAN_HAL_Disable (CAN_Type * base)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

0 if successful; non-zero failed

21.3.4.3 flexcan_status_t FLEXCAN_HAL_SelectClock (CAN_Type * base, flexcan_clk_source_t clk)

Parameters

FlexCAN HAL driver

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>clk</i> | The FlexCAN clock source |

Returns

0 if successful; non-zero failed

21.3.4.4 static bool FLEXCAN_HAL_GetClock (CAN_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

0: if clock source is oscillator clock, 1: if clock source is peripheral clock

21.3.4.5 flexcan_status_t FLEXCAN_HAL_Init (CAN_Type * *base*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

0 if successful; non-zero failed

21.3.4.6 void FLEXCAN_HAL_SetTimeSegments (CAN_Type * *base*, flexcan_time_segment_t * *timeSeg*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

| | |
|----------------|---|
| <i>timeSeg</i> | FlexCAN time segments, which need to be set for the bit rate. |
|----------------|---|

21.3.4.7 void FLEXCAN_HAL_GetTimeSegments (CAN_Type * *base*, flexcan_time_segment_t * *timeSeg*)

Parameters

| | |
|----------------|---|
| <i>base</i> | The FlexCAN base address |
| <i>timeSeg</i> | FlexCAN time segments read for bit rate |

21.3.4.8 void FLEXCAN_HAL_ExitFreezeMode (CAN_Type * *base*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

21.3.4.9 void FLEXCAN_HAL_EnterFreezeMode (CAN_Type * *base*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

21.3.4.10 flexcan_status_t FLEXCAN_HAL_SetOperationMode (CAN_Type * *base*, flexcan_operation_modes_t *mode*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>mode</i> | Set an operation mode |

Returns

0 if successful; non-zero failed.

21.3.4.11 flexcan_status_t FLEXCAN_HAL_ExitOperationMode (CAN_Type * *base*, flexcan_operation_modes_t *mode*)

FlexCAN HAL driver

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>mode</i> | Exit An operation mode |

Returns

0 if successful; non-zero failed.

21.3.4.12 flexcan_status_t FLEXCAN_HAL_SetTxMsgBuff (CAN_Type * *base*, uint32_t *msgBuffIdx*, flexcan_msgbuff_code_status_t * *cs*, uint32_t *msgId*, uint8_t * *msgData*)

Parameters

| | |
|-------------------|-------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>cs</i> | CODE/status values (TX) |
| <i>msgId</i> | ID of the message to transmit |
| <i>msgData</i> | Bytes of the FlexCAN message |

Returns

0 if successful; non-zero failed

21.3.4.13 flexcan_status_t FLEXCAN_HAL_SetRxMsgBuff (CAN_Type * *base*, uint32_t *msgBuffIdx*, flexcan_msgbuff_code_status_t * *cs*, uint32_t *msgId*)

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>cs</i> | CODE/status values (RX) |

| | |
|--------------|------------------------------|
| <i>msgId</i> | ID of the message to receive |
|--------------|------------------------------|

Returns

0 if successful; non-zero failed

21.3.4.14 flexcan_status_t FLEXCAN_HAL_GetMsgBuff (CAN_Type * *base*, uint32_t *msgBuffIdx*, flexcan_msgbuff_t * *msgBuff*)

Parameters

| | |
|-------------------|----------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>msgBuff</i> | The fields of the message buffer |

Returns

0 if successful; non-zero failed

21.3.4.15 flexcan_status_t FLEXCAN_HAL_LockRxMsgBuff (CAN_Type * *base*, uint32_t *msgBuffIdx*)

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |

Returns

0 if successful; non-zero failed

**21.3.4.16 static uint32_t FLEXCAN_HAL_UnlockRxMsgBuff (CAN_Type * *base*)
[inline], [static]**

FlexCAN HAL driver

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

0 if successful; non-zero failed

21.3.4.17 void FLEXCAN_HAL_EnableRxFifo (CAN_Type * *base*, uint32_t *numOfFilters*)

Parameters

| | |
|---------------------|------------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>numOfFilters</i> | The number of receive FIFO filters |

21.3.4.18 void FLEXCAN_HAL_DisableRxFifo (CAN_Type * *base*)

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

21.3.4.19 void FLEXCAN_HAL_SetRxFifoFilterNum (CAN_Type * *base*, uint32_t *number*)

Parameters

| | |
|---------------|------------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>number</i> | The number of receive FIFO filters |

21.3.4.20 void FLEXCAN_HAL_SetMaxMsgBuffNum (CAN_Type * *base*, uint32_t *maxMsgBuffNum*)

Parameters

| | |
|-----------------------|-----------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>maxMsgBuff-Num</i> | Number of the last Message Buffer |

21.3.4.21 flexcan_status_t FLEXCAN_HAL_SetRxFifoFilter (CAN_Type * *base*, flexcan_rx_fifo_id_element_format_t *idFormat*, flexcan_id_table_t * *idFilterTable*)

Parameters

| | |
|----------------------|--|
| <i>base</i> | The FlexCAN base address |
| <i>idFormat</i> | The format of the receive FIFO ID Filter Table Elements |
| <i>idFilterTable</i> | The ID filter table elements which contain RTR bit, IDE bit, and receive message ID. |

Returns

0 if successful; non-zero failed.

21.3.4.22 flexcan_status_t FLEXCAN_HAL_ReadRxFifo (CAN_Type * *base*, flexcan_msgbuff_t * *rxFifo*)

Parameters

| | |
|---------------|-------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>rxFifo</i> | The FlexCAN receive FIFO data |

Returns

0 if successful; non-zero failed.

21.3.4.23 flexcan_status_t FLEXCAN_HAL_SetMsgBuffIntCmd (CAN_Type * *base*, uint32_t *msgBuffIdx*, bool *enable*)

FlexCAN HAL driver

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>enable</i> | choose enable or disable |

Returns

0 if successful; non-zero failed

21.3.4.24 `void FLEXCAN_HAL_SetErrIntCmd (CAN_Type * base, flexcan_int_type_t errType, bool enable)`

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>errType</i> | The interrupt type |
| <i>enable</i> | choose enable or disable |

21.3.4.25 `static uint32_t FLEXCAN_HAL_GetFreezeAck (CAN_Type * base) [inline], [static]`

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

freeze ACK state (1-freeze mode, 0-not in freeze mode).

21.3.4.26 `uint8_t FLEXCAN_HAL_GetMsgBuffIntStatusFlag (CAN_Type * base, uint32_t msgBuffIdx)`

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |

Returns

the individual Message Buffer interrupt flag (0 and 1 are the flag value)

21.3.4.27 `static uint32_t FLEXCAN_HAL_GetAllMsgBuffIntStatusFlag (CAN_Type * base) [inline], [static]`

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

all MB interrupt flags

21.3.4.28 `static void FLEXCAN_HAL_ClearMsgBuffIntStatusFlag (CAN_Type * base, uint32_t flag) [inline], [static]`

Parameters

| | |
|-------------|--|
| <i>base</i> | The FlexCAN base address |
| <i>flag</i> | The value to be written to the interrupt flag1 register. |

21.3.4.29 `void FLEXCAN_HAL_GetErrCounter (CAN_Type * base, flexcan_buserr_counter_t * errCount)`

Parameters

| | |
|-----------------|--|
| <i>base</i> | The FlexCAN base address |
| <i>errCount</i> | Transmit error counter and receive error counter |

FlexCAN HAL driver

21.3.4.30 `static uint32_t FLEXCAN_HAL_GetErrStatus (CAN_Type * base) [inline], [static]`

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

The current error and status

21.3.4.31 `void FLEXCAN_HAL_ClearErrIntStatusFlag (CAN_Type * base)`

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

21.3.4.32 `void FLEXCAN_HAL_SetRxMaskType (CAN_Type * base, flexcan_rx_mask_type_t type)`

Parameters

| | |
|-------------|-------------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>type</i> | The FlexCAN receive mask type |

21.3.4.33 `void FLEXCAN_HAL_SetRxFifoGlobalStdMask (CAN_Type * base, uint32_t stdMask)`

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

| | |
|----------------|---------------|
| <i>stdMask</i> | Standard mask |
|----------------|---------------|

21.3.4.34 void FLEXCAN_HAL_SetRxFifoGlobalExtMask (CAN_Type * *base*, uint32_t *extMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>extMask</i> | Extended mask |

21.3.4.35 flexcan_status_t FLEXCAN_HAL_SetRxIndividualStdMask (CAN_Type * *base*, uint32_t *msgBuffIdx*, uint32_t *stdMask*)

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>stdMask</i> | Individual standard mask |

Returns

0 if successful; non-zero failed

21.3.4.36 flexcan_status_t FLEXCAN_HAL_SetRxIndividualExtMask (CAN_Type * *base*, uint32_t *msgBuffIdx*, uint32_t *extMask*)

Parameters

| | |
|-------------------|-----------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>msgBuffIdx</i> | Index of the message buffer |
| <i>extMask</i> | Individual extended mask |

Returns

0 if successful; non-zero failed

21.3.4.37 void FLEXCAN_HAL_SetRxMsgBuffGlobalStdMask (CAN_Type * *base*, uint32_t *stdMask*)

FlexCAN HAL driver

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>stdMask</i> | Standard mask |

21.3.4.38 void FLEXCAN_HAL_SetRxMsgBuff14StdMask (CAN_Type * *base*, uint32_t *stdMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>stdMask</i> | Standard mask |

21.3.4.39 void FLEXCAN_HAL_SetRxMsgBuff15StdMask (CAN_Type * *base*, uint32_t *stdMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>stdMask</i> | Standard mask |

21.3.4.40 void FLEXCAN_HAL_SetRxMsgBuffGlobalExtMask (CAN_Type * *base*, uint32_t *extMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>extMask</i> | Extended mask |

21.3.4.41 void FLEXCAN_HAL_SetRxMsgBuff14ExtMask (CAN_Type * *base*, uint32_t *extMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>extMask</i> | Extended mask |

21.3.4.42 void FLEXCAN_HAL_SetRxMsgBuff15ExtMask (CAN_Type * *base*, uint32_t *extMask*)

Parameters

| | |
|----------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
| <i>extMask</i> | Extended mask |

21.3.4.43 static uint32_t FLEXCAN_HAL_GetRxFifoHitIdAcceptanceFilter (CAN_Type * *base*) [inline], [static]

Parameters

| | |
|-------------|--------------------------|
| <i>base</i> | The FlexCAN base address |
|-------------|--------------------------|

Returns

receive FIFO information

Chapter 22

External Bus Interface (FLEXBUS)

22.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the External Bus Interface (FLEXBUS) block of Kinetis devices.

Modules

- [FLEXBUS HAL driver](#)
- [FLEXBUS Peripheral Driver](#)

FLEXBUS HAL driver

22.2 FLEXBUS HAL driver

22.2.1 Overview

The section describes the programming interface of the FLEXBUS HAL driver.

Files

- file [fsl_flexbus_hal.h](#)

Data Structures

- struct [flexbus_user_config_t](#)
Configuration structure that the user needs to set. [More...](#)

Enumerations

- enum [flexbus_status_t](#)
Flexbus status return codes.
- enum [flexbus_port_size_t](#) {
[kFlexbus4bytes](#) = 0x00U,
[kFlexbus1byte](#) = 0x01U,
[kFlexbus2bytes](#) = 0x02U }
Defines port size for Flexbus peripheral.
- enum [flexbus_write_address_hold_t](#) {
[kFlexbusHold1cycle](#) = 0x00U,
[kFlexbusHold2cycles](#) = 0x01U,
[kFlexbusHold3cycles](#) = 0x02U,
[kFlexbusHold4cycles](#) = 0x03U }
Defines number of cycles to hold address and attributes for Flexbus peripheral.
- enum [flexbus_read_address_hold_t](#) {
[kFlexbusHold4or3cycles](#) = 0x03U,
[kFlexbusHold3or2cycles](#) = 0x02U,
[kFlexbusHold2or1cycle](#) = 0x01U,
[kFlexbusHold1or0cycle](#) = 0x00U }
Defines number of cycles to hold address and attributes for Flexbus peripheral.
- enum [flexbus_address_setup_t](#) {
[kFlexbusFirstRisingEdge](#) = 0x00U,
[kFlexbusSecondRisingEdge](#) = 0x01U,
[kFlexbusThirdRisingEdge](#) = 0x02U,
[kFlexbusFourthRisingEdge](#) = 0x03U }
Address setup for Flexbus peripheral.
- enum [flexbus_bytelane_shift_t](#) {
[kFlexbusNotShifted](#) = 0x00U,
[kFlexbusShifted](#) = 0x01U }

- Defines byte-lane shift for Flexbus peripheral.*

 - enum `flexbus_multiplex_group1_t` {
`kFlexbusMultiplexGroup1_FB_ALE` = 0x00U,
`kFlexbusMultiplexGroup1_FB_CS1` = 0x01U,
`kFlexbusMultiplexGroup1_FB_TS` = 0x02U }

Defines multiplex group1 valid signals.

 - enum `flexbus_multiplex_group2_t` {
`kFlexbusMultiplexGroup2_FB_CS4` = 0x00U,
`kFlexbusMultiplexGroup2_FB_TSIZ0` = 0x01U,
`kFlexbusMultiplexGroup2_FB_BE_31_24` = 0x02U }

Defines multiplex group2 valid signals.

 - enum `flexbus_multiplex_group3_t` {
`kFlexbusMultiplexGroup3_FB_CS5` = 0x00U,
`kFlexbusMultiplexGroup3_FB_TSIZ1` = 0x01U,
`kFlexbusMultiplexGroup3_FB_BE_23_16` = 0x02U }

Defines multiplex group3 valid signals.

 - enum `flexbus_multiplex_group4_t` {
`kFlexbusMultiplexGroup4_FB_TBST` = 0x00U,
`kFlexbusMultiplexGroup4_FB_CS2` = 0x01U,
`kFlexbusMultiplexGroup4_FB_BE_15_8` = 0x02U }

Defines multiplex group4 valid signals.

 - enum `flexbus_multiplex_group5_t` {
`kFlexbusMultiplexGroup5_FB_TA` = 0x00U,
`kFlexbusMultiplexGroup5_FB_CS3` = 0x01U,
`kFlexbusMultiplexGroup5_FB_BE_7_0` = 0x02U }

Defines multiplex group5 valid signals.

Configuration

- void `FLEXBUS_HAL_Init` (FB_Type *base)
Initialization to default values.
- void `FLEXBUS_HAL_Configure` (FB_Type *base, const `flexbus_user_config_t` *userConfigPtr)
Configure to a known values.
- static void `FLEXBUS_HAL_WriteAddr` (FB_Type *base, uint8_t chip, uint16_t addr, uint16_t addrMask)
Write chip-select base address.
- static void `FLEXBUS_HAL_SetChipSelectValidCmd` (FB_Type *base, uint8_t chip, bool valid)
Sets chip-selects valid bit or not.
- static void `FLEXBUS_HAL_SetWriteProtectionCmd` (FB_Type *base, uint8_t chip, bool enable)
Enables or disables write protection function for Flexbus.
- static void `FLEXBUS_HAL_SetBurstWriteCmd` (FB_Type *base, uint8_t chip, bool enable)
Enables or disables burst-write on Flexbus.
- static void `FLEXBUS_HAL_SetBurstReadCmd` (FB_Type *base, uint8_t chip, bool enable)
Enables or disables burst-read bit on Flexbus.
- static void `FLEXBUS_HAL_SetByteModeCmd` (FB_Type *base, uint8_t chip, bool enable)
Enables or disables byte-enable support on Flexbus.
- static void `FLEXBUS_HAL_SetPortSize` (FB_Type *base, uint8_t chip, `flexbus_port_size_t` size)
Sets port size on Flexbus.

FLEXBUS HAL driver

- static void `FLEXBUS_HAL_SetAutoAcknowledgeCmd` (`FB_Type *base`, `uint8_t chip`, `bool enable`)
Enables auto-acknowledge on Flexbus.
- static void `FLEXBUS_HAL_SetByteLaneShift` (`FB_Type *base`, `uint8_t chip`, `flexbus_bytelane_shift_t shift`)
Enables byte-lane shift on Flexbus.
- static void `FLEXBUS_HAL_SetWaitStates` (`FB_Type *base`, `uint8_t chip`, `uint8_t waitStates`)
Sets number of wait states on Flexbus.
- static void `FLEXBUS_HAL_SetWriteAddrHoldOrDeselect` (`FB_Type *base`, `uint8_t chip`, `flexbus_write_address_hold_t addrHold`)
Sets write address hold or deselect.
- static void `FLEXBUS_HAL_SetReadAddrHoldOrDeselect` (`FB_Type *base`, `uint8_t chip`, `flexbus_read_address_hold_t addrHold`)
Sets read address hold or deselect.
- static void `FLEXBUS_HAL_SetAddrSetup` (`FB_Type *base`, `uint8_t chip`, `flexbus_address_setup_t delay`)
Set address setup.
- static void `FLEXBUS_HAL_SetExtendedAddrLatchCmd` (`FB_Type *base`, `uint8_t chip`, `bool enable`)
Enables extended address latch.
- static void `FLEXBUS_HAL_SetSecondaryWaitStateCmd` (`FB_Type *base`, `uint8_t chip`, `bool enable`)
Enables secondary wait state.
- static void `FLEXBUS_HAL_SetMultiplexControlGroup1` (`FB_Type *base`, `flexbus_multiplex_group1_t controls`)
Multiplex group1 set.
- static `flexbus_multiplex_group1_t FLEXBUS_HAL_GetMultiplexControlGroup1` (`FB_Type *base`)
Multiplex group1 get.
- static void `FLEXBUS_HAL_SetMultiplexControlGroup2` (`FB_Type *base`, `flexbus_multiplex_group2_t controls`)
Multiplex group2 set.
- static `flexbus_multiplex_group2_t FLEXBUS_HAL_GetMultiplexControlGroup2` (`FB_Type *base`)
Multiplex group2 get.
- static void `FLEXBUS_HAL_SetMultiplexControlGroup3` (`FB_Type *base`, `flexbus_multiplex_group3_t controls`)
Multiplex group3 set.
- static `flexbus_multiplex_group3_t FLEXBUS_HAL_GetMultiplexControlGroup3` (`FB_Type *base`)
Multiplex group3 get.
- static void `FLEXBUS_HAL_SetMultiplexControlGroup4` (`FB_Type *base`, `flexbus_multiplex_group4_t controls`)
Multiplex group4 set.
- static `flexbus_multiplex_group4_t FLEXBUS_HAL_GetMultiplexControlGroup4` (`FB_Type *base`)
Multiplex group4 get.
- static void `FLEXBUS_HAL_SetMultiplexControlGroup5` (`FB_Type *base`, `flexbus_multiplex_group5_t controls`)

- Multiplex group5 set.*

 - static `flexbus_multiplex_group5_t` `FLEXBUS_HAL_GetMultiplexControlGroup5` (`FB_Type *base`)

Multiplex group5 get.

22.2.2 Data Structure Documentation

22.2.2.1 struct flexbus_user_config_t

Data Fields

- `uint8_t` `chip`
Chip FlexBus for validation.
- `uint8_t` `waitStates`
Value of wait states.
- `uint32_t` `baseAddress`
Base address for using FlexBus.
- `uint32_t` `baseAddressMask`
Base address mask.
- `bool` `writeProtect`
Write protected.
- `bool` `burstWrite`
Burst-Write enable.
- `bool` `burstRead`
Burst-Read enable.
- `bool` `byteEnableMode`
Byte-enable mode support.
- `bool` `autoAcknowledge`
Auto acknowledge setting.
- `bool` `extendTransferAddress`
Extend transfer start/extend address latch enable.
- `bool` `secondaryWaitStates`
Secondary wait states number.
- `flexbus_port_size_t` `portSize`
Port size of transfer.
- `flexbus_bytelane_shift_t` `byteLaneShift`
Byte-lane shift enable.
- `flexbus_write_address_hold_t` `writeAddressHold`
Write address hold or deselect option.
- `flexbus_read_address_hold_t` `readAddressHold`
Read address hold or deselect option.
- `flexbus_address_setup_t` `addressSetup`
Address setup setting.
- `flexbus_multiplex_group1_t` `group1MultiplexControl`
FlexBus Signal Group 1 Multiplex control.
- `flexbus_multiplex_group2_t` `group2MultiplexControl`
FlexBus Signal Group 2 Multiplex control.
- `flexbus_multiplex_group3_t` `group3MultiplexControl`
FlexBus Signal Group 3 Multiplex control.

FLEXBUS HAL driver

- [flexbus_multiplex_group4_t group4MultiplexControl](#)
FlexBus Signal Group 4 Multiplex control.
- [flexbus_multiplex_group5_t group5MultiplexControl](#)
FlexBus Signal Group 5 Multiplex control.

22.2.3 Enumeration Type Documentation

22.2.3.1 enum flexbus_status_t

22.2.3.2 enum flexbus_port_size_t

Enumerator

- kFlexbus4bytes* 32-bit port size
- kFlexbus1byte* 8-bit port size
- kFlexbus2bytes* 16-bit port size

22.2.3.3 enum flexbus_write_address_hold_t

Enumerator

- kFlexbusHold1cycle* Hold address and attributes one cycle after FB_CS_n negates on writes.
- kFlexbusHold2cycles* Hold address and attributes two cycle after FB_CS_n negates on writes.
- kFlexbusHold3cycles* Hold address and attributes three cycle after FB_CS_n negates on writes.
- kFlexbusHold4cycles* Hold address and attributes four cycle after FB_CS_n negates on writes.

22.2.3.4 enum flexbus_read_address_hold_t

Enumerator

- kFlexbusHold4or3cycles* Hold address and attributes 4 or 3 cycles on reads.
- kFlexbusHold3or2cycles* Hold address and attributes 3 or 2 cycles on reads.
- kFlexbusHold2or1cycle* Hold address and attributes 2 or 1 cycles on reads.
- kFlexbusHold1or0cycle* Hold address and attributes 1 or 0 cycles on reads.

22.2.3.5 enum flexbus_address_setup_t

Enumerator

- kFlexbusFirstRisingEdge* Assert FB_CS_n on first rising clock edge after address is asserted.
- kFlexbusSecondRisingEdge* Assert FB_CS_n on second rising clock edge after address is asserted.
- kFlexbusThirdRisingEdge* Assert FB_CS_n on third rising clock edge after address is asserted.
- kFlexbusFourthRisingEdge* Assert FB_CS_n on fourth rising clock edge after address is asserted.

22.2.3.6 enum flexbus_bytelane_shift_t

Enumerator

kFlexbusNotShifted Not shifted. Data is left-justified on FB_AD.

kFlexbusShifted Shifted. Data is right justified on FB_AD.

22.2.3.7 enum flexbus_multiplex_group1_t

Enumerator

kFlexbusMultiplexGroup1_FB_ALE FB_ALE.

kFlexbusMultiplexGroup1_FB_CS1 FB_CS1.

kFlexbusMultiplexGroup1_FB_TS FB_TS.

22.2.3.8 enum flexbus_multiplex_group2_t

Enumerator

kFlexbusMultiplexGroup2_FB_CS4 FB_CS4.

kFlexbusMultiplexGroup2_FB_TSIZ0 FB_TSIZ0.

kFlexbusMultiplexGroup2_FB_BE_31_24 FB_BE_31_24.

22.2.3.9 enum flexbus_multiplex_group3_t

Enumerator

kFlexbusMultiplexGroup3_FB_CS5 FB_CS5.

kFlexbusMultiplexGroup3_FB_TSIZ1 FB_TSIZ1.

kFlexbusMultiplexGroup3_FB_BE_23_16 FB_BE_23_16.

22.2.3.10 enum flexbus_multiplex_group4_t

Enumerator

kFlexbusMultiplexGroup4_FB_TBST FB_TBST.

kFlexbusMultiplexGroup4_FB_CS2 FB_CS2.

kFlexbusMultiplexGroup4_FB_BE_15_8 FB_BE_15_8.

FLEXBUS HAL driver

22.2.3.11 enum flexbus_multiplex_group5_t

Enumerator

kFlexbusMultiplexGroup5_FB_TA FB_TA.
kFlexbusMultiplexGroup5_FB_CS3 FB_CS3.
kFlexbusMultiplexGroup5_FB_BE_7_0 FB_BE_7_0.

22.2.4 Function Documentation

22.2.4.1 void FLEXBUS_HAL_Init (FB_Type * *base*)

Only chip 0 validated and set to known values. Other chips disabled.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

22.2.4.2 void FLEXBUS_HAL_Configure (FB_Type * *base*, const flexbus_user_config_t * *userConfigPtr*)

Parameters

| | |
|----------------------|----------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>userConfigPtr</i> | Flexbus input user configuration |

22.2.4.3 static void FLEXBUS_HAL_WriteAddr (FB_Type * *base*, uint8_t *chip*, uint16_t *addr*, uint16_t *addrMask*) [inline], [static]

The CSARn registers specify the chip-select base addresses. NOTE: Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. Refer to the device memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSARn registers appropriately.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

| | |
|-----------------|--------------------------------|
| <i>chip</i> | Flexbus chip for validation. |
| <i>addr</i> | chip-select base address. |
| <i>addrMask</i> | chip-select base address mask. |

22.2.4.4 **static void FLEXBUS_HAL_SetChipSelectValidCmd (FB_Type * *base*, uint8_t *chip*, bool *valid*) [inline], [static]**

Indicates whether the corresponding CSAR, CSMR, and CSCR contents are valid. NOTE: At reset, no chip-select other than FB_CS0 can be used until the CSMR0[V] is set. Afterward, FB_CS[5:0] functions as programmed.

Parameters

| | |
|--------------|---|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>valid</i> | Validation for chip-selects or not. <ul style="list-style-type: none"> • true: chip-select is valid • false: chip-select is invalid |

22.2.4.5 **static void FLEXBUS_HAL_SetWriteProtectionCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]**

Controls write accesses to the address range in the corresponding CSAR. 0: Read and write accesses are allowed 1: Only read accesses are allowed

Parameters

| | |
|---------------|---------------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables write protection. |

22.2.4.6 **static void FLEXBUS_HAL_SetBurstWriteCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]**

Specifies whether burst writes are used for memory associated with each FB_CS_n.

0: Break data larger than the specified port size into individual, port-sized, non-burst writes. For example, a longword write to an 8-bit port takes four byte writes. 1: Enables burst write of data larger than the

FLEXBUS HAL driver

specified port size, including longword writes to 8 and 16-bit ports, word writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.

Parameters

| | |
|---------------|----------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables burst-write. |

22.2.4.7 static void FLEXBUS_HAL_SetBurstReadCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]

Specifies whether burst reads are used for memory associated with each FB_CS_n.

0: Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a longword read from an 8-bit port is broken into four 8-bit reads. 1: Enables data burst reads larger than the specified port size, including longword reads from 8- and 16-bit ports, word reads from 8-bit ports, and line reads from 8, 16-, and 32-bit ports.

Parameters

| | |
|---------------|---------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables burst-read. |

22.2.4.8 static void FLEXBUS_HAL_SetByteModeCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]

Specifies the byte enable operation. Certain memories have byte enables that must be asserted during reads and writes. BEM can be set in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs.

The FB_BEn signals are asserted for read and write accesses.

Parameters

| | |
|---------------|---|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables byte-enable support |

FLEXBUS HAL driver

22.2.4.9 static void FLEXBUS_HAL_SetPortSize (FB_Type * *base*, uint8_t *chip*, flexbus_port_size_t *size*) [inline], [static]

Specifies the data port width associated with each chip-select. It determines where data is driven during write cycles and where data is sampled during read cycles.

Parameters

| | |
|-------------|------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>size</i> | Size of port. |

22.2.4.10 static void FLEXBUS_HAL_SetAutoAcknowledgeCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]

Determines the assertion of the internal transfer acknowledge for accesses specified by the chip-select address.

NOTE: If AA is set for a corresponding FB_CS_n and the external system asserts an external FB_TA before the wait-state countdown asserts the internal FB_TA, the cycle is terminated. Burst cycles increment the address bus between each internal termination. NOTE: This bit must be set if CSPMCR disables FB_TA.

enable value: 0: No internal FB_TA is asserted. Cycle is terminated externally 1: Internal transfer acknowledge is asserted as specified by WS

Parameters

| | |
|---------------|---------------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables Auto-acknowledge. |

22.2.4.11 static void FLEXBUS_HAL_SetByteLaneShift (FB_Type * *base*, uint8_t *chip*, flexbus_bytelane_shift_t *shift*) [inline], [static]

Determines if data on FB_AD appears left-justified or right-justified during the data phase of a FlexBus access.

0: Not shifted. Data is left-justified on FB_AD. 1: Shifted. Data is right justified on FB_AD.

Parameters

| | |
|--------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>shift</i> | Selects left-justified or right-justified data |

22.2.4.12 static void FLEXBUS_HAL_SetWaitStates (FB_Type * *base*, uint8_t *chip*, uint8_t *waitStates*) [inline], [static]

The number of wait states inserted after FB_CS_n asserts and before an internal transfer acknowledge is generated (WS = 0 inserts zero wait states, WS = 0x3F inserts 63 wait states).

Parameters

| | |
|-------------------|------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>waitStates</i> | Defines value of wait states |

22.2.4.13 static void FLEXBUS_HAL_SetWriteAddrHoldOrDeselect (FB_Type * *base*, uint8_t *chip*, flexbus_write_address_hold_t *addrHold*) [inline], [static]

Write address hold or deselect. This field controls the address, data, and attribute hold time after the termination of a write cycle that hits in the chip-select address space. NOTE: The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>addrHold</i> | Value of cycles to hold write address. |

22.2.4.14 static void FLEXBUS_HAL_SetReadAddrHoldOrDeselect (FB_Type * *base*, uint8_t *chip*, flexbus_read_address_hold_t *addrHold*) [inline], [static]

This field controls the address and attribute hold time after the termination during a read cycle that hits in the chip-select address space. NOTE: The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.

FLEXBUS HAL driver

Parameters

| | |
|-----------------|---------------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>addrHold</i> | Value of cycles to hold read address. |

22.2.4.15 static void FLEXBUS_HAL_SetAddrSetup (FB_Type * *base*, uint8_t *chip*, flexbus_address_setup_t *delay*) [inline], [static]

Controls the assertion of the chip-select with respect to assertion of a valid address and attributes. The address and attributes are considered valid at the same time FB_TS/FB_ALE asserts.

Parameters

| | |
|--------------|------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>delay</i> | Value of delay. |

22.2.4.16 static void FLEXBUS_HAL_SetExtendedAddrLatchCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]

Extended address latch enable

0: FB_TS/FB_ALE asserts for one bus clock cycle. 1: FB_TS/FB_ALE remains asserted until the first positive clock edge after FB_CS_n asserts.

Parameters

| | |
|---------------|---|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables extended address latch. |

22.2.4.17 static void FLEXBUS_HAL_SetSecondaryWaitStateCmd (FB_Type * *base*, uint8_t *chip*, bool *enable*) [inline], [static]

Secondary wait state enable.

0: The WS value inserts wait states before an internal transfer acknowledge is generated for all transfers.
1: The SWS value inserts wait states before an internal transfer acknowledge is generated for burst transfer secondary terminations.

Parameters

| | |
|---------------|--------------------------------|
| <i>base</i> | Flexbus module base number. |
| <i>chip</i> | Flexbus chip for validation. |
| <i>enable</i> | Enables or disables wait state |

22.2.4.18 static void FLEXBUS_HAL_SetMultiplexControlGroup1 (FB_Type * *base*, flexbus_multiplex_group1_t *controls*) [inline], [static]

GROUP1 Controls the multiplexing of the FB_ALE, FB_CS1 , and FB_TS signals.

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>controls</i> | Flexbus multiplex settings for Group1. |

Returns

Flexbus status.

22.2.4.19 static flexbus_multiplex_group1_t FLEXBUS_HAL_GetMultiplexControlGroup1 (FB_Type * *base*) [inline], [static]

GROUP1 Controls the multiplexing of the FB_ALE, FB_CS1 , and FB_TS signals.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

Returns

Flexbus multiplex settings for Group1.

22.2.4.20 static void FLEXBUS_HAL_SetMultiplexControlGroup2 (FB_Type * *base*, flexbus_multiplex_group2_t *controls*) [inline], [static]

GROUP2 Controls the multiplexing of the FB_TA , FB_CS3 , and FB_BE_7_0 signals. When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer.

FLEXBUS HAL driver

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>controls</i> | Flexbus multiplex settings for Group2. |

Returns

Flexbus status.

22.2.4.21 **static flexbus_multiplex_group2_t FLEXBUS_HAL_GetMultiplexControlGroup2 (FB_Type * *base*) [inline], [static]**

GROUP2 Controls the multiplexing of the FB_TA , FB_CS3 , and FB_BE_7_0 signals. When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

Returns

Flexbus multiplex settings for Group2.

22.2.4.22 **static void FLEXBUS_HAL_SetMultiplexControlGroup3 (FB_Type * *base*, flexbus_multiplex_group3_t *controls*) [inline], [static]**

GROUP3 Controls the multiplexing of the FB_CS4 , FB_TSIZ0, and FB_BE_31_24 signals.

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>controls</i> | Flexbus multiplex settings for Group3. |

Returns

Flexbus status.

22.2.4.23 **static flexbus_multiplex_group3_t FLEXBUS_HAL_GetMultiplexControlGroup3 (FB_Type * *base*) [inline], [static]**

GROUP3 Controls the multiplexing of the FB_CS4 , FB_TSIZ0, and FB_BE_31_24 signals.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

Returns

Flexbus multiplex settings for Group3.

22.2.4.24 static void FLEXBUS_HAL_SetMultiplexControlGroup4 (FB_Type * *base*, flexbus_multiplex_group4_t *controls*) [inline], [static]

GROUP4 Controls the multiplexing of the FB_TBST, FB_CS2, and FB_BE_15_8 signals.

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>controls</i> | Flexbus multiplex settings for Group4. |

Returns

Flexbus status.

22.2.4.25 static flexbus_multiplex_group4_t FLEXBUS_HAL_GetMultiplexControlGroup4 (FB_Type * *base*) [inline], [static]

GROUP4 Controls the multiplexing of the FB_TBST, FB_CS2, and FB_BE_15_8 signals.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

Returns

Flexbus multiplex settings for Group4.

22.2.4.26 static void FLEXBUS_HAL_SetMultiplexControlGroup5 (FB_Type * *base*, flexbus_multiplex_group5_t *controls*) [inline], [static]

GROUP5 Controls the multiplexing of the FB_TA, FB_CS3, and FB_BE_7_0 signals.

FLEXBUS HAL driver

Parameters

| | |
|-----------------|--|
| <i>base</i> | Flexbus module base number. |
| <i>controls</i> | Flexbus multiplex settings for Group5. |

Returns

Flexbus status.

22.2.4.27 `static flexbus_multiplex_group5_t FLEXBUS_HAL_GetMultiplexControlGroup5 (FB_Type * base) [inline], [static]`

GROUP5 Controls the multiplexing of the FB_TA, FB_CS3, and FB_BE_7_0 signals.

Parameters

| | |
|-------------|-----------------------------|
| <i>base</i> | Flexbus module base number. |
|-------------|-----------------------------|

Returns

Flexbus multiplex settings for Group5.

22.3 FLEXBUS Peripheral Driver

22.3.1 Overview

The section describes the programming interface of the FLEXBUS Peripheral driver. The FLEXBUS driver provides an easy way to initialize and configure the FLEXBUS.

22.3.2 FLEXBUS Overview

The FLEXBUS (external bus interface) is a hardware module that provides memory expansion and a connection to external peripheral with a parallel bus. It can be directly connected to the slave-only devices such as:

- External ROMs
- Flash memories
- Programmable logic devices
- Other simple target (slave) devices

22.3.3 FLEXBUS Initialization

To initialize the FLEXBUS module, call the [FLEXBUS_DRV_Init\(\)](#) function and pass in the instance number and the user configuration structure. This function automatically enables the FLEXBUS module and clock.

This example code shows how to initialize and configure the FLEXBUS for MRAM purpose:

```
/* Define configuration.
flexbus_user_config_t fb_config;
/* Clear user configuration struct first.
memset(&fb_config, 0x0, sizeof(flexbus_user_config_t));
fb_config.chip = 0;
fb_config.baseAddress = 0x60000000; /* Configure base address.
fb_config.portSize = kFlexbus1byte; /* Port size of transfer.
fb_config.autoAcknowledge = true; /* Enable auto acknowledge.
fb_config.waitStates = 0x2; /* Set wait state.
fb_config.baseAddressMask = 0x7; /* Configure base address mask.

/* Initialize FLEXBUS.
FLEXBUS_DRV_Init(instance, &fb_config);
```

22.3.4 FLEXBUS De-initialize

To shut down the FLEXBUS module, call the [FLEXBUS_DRV_Deinit\(\)](#) function and pass in the instance number.

```
FLEXBUS_DRV_Deinit(instance);
```

FLEXBUS Peripheral Driver

Functions

- `flexbus_status_t FLEXBUS_DRV_Init (uint32_t instance, const flexbus_user_config_t *fb_config)`
Initializes the FlexBus driver.
- `flexbus_status_t FLEXBUS_DRV_Deinit (uint32_t instance)`
Shuts down the FlexBus driver.

Variables

- `FB_Type *const g_fbBase []`
Table of base addresses for FlexBus instances.

22.3.5 Function Documentation

22.3.5.1 flexbus_status_t FLEXBUS_DRV_Init (uint32_t instance, const flexbus_user_config_t * fb_config)

Parameters

| | |
|------------------|---|
| <i>instance</i> | The FlexBus peripheral instance number. |
| <i>fb_config</i> | FlexBus input user configuration |

Returns

Execution status.

22.3.5.2 flexbus_status_t FLEXBUS_DRV_Deinit (uint32_t instance)

Parameters

| | |
|-----------------|---|
| <i>instance</i> | The FlexBus peripheral instance number. |
|-----------------|---|

Returns

Execution status.

22.3.6 Variable Documentation

22.3.6.1 FB_Type* const g_fbBase[]

Chapter 23

FlexIO (FLEXIO)

23.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for basic FlexIO operation.

Modules

- [FlexIO basic HAL Driver](#)
- [FlexIO basic Peripheral Driver](#)

FlexIO basic HAL Driver

23.2 FlexIO basic HAL Driver

23.2.1 Overview

This section describes the programming interface of the FlexIO basic HAL driver.

23.2.2 Basic concept for FlexIO programming

FlexIO is a module that can be used to simulate multiple communication interfaces. The FlexIO can work by assembling pins, shifters, and timers with the appropriate configuration.

The pin is bonded to shifter and timer and is usually an external interface to other devices.

- When the pin is bonded to a shifter, it can be used to output the data shifted from the shifter's buffer, or as the input signal that is sampled by shifter. In this case, the setting for the pin is involved in bonded shifter's configuration.
- When the pin is bonded to a timer, it can be used as a trigger to enable/disable the timer. When the timer is enabled, the pin can also act as a channel of the input/output clock signal, in the same way it is used for the shifter. In this case, the setting for the pin is involved in the bonded timer's configuration.

The FlexIO 32-bit shifter is the data interface to the modules inside the chip. Shifters are responsible for buffering and shifting data in or out of the FlexIO. The timing of a shift, load and store events are controlled by the timer assigned to the shifter via the SHIFTCTL[TIMSEL] register. This setting creates the relationship between the shifter and the timer. Shifters are designed to support either DMA, interrupt or polled operation. Corresponding switchers generate triggers for the DMA or the interrupt request.

For advanced versions of the FlexIO module, there is a parallel mode for the shifter, which means that one shifter can be connected to more than one pins and the count of shift bits per shifter clock is related to the pin number.

The FlexIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the comparison register and decrement down to zero on the FlexIO clock.

- Enabling the timer; Timers can be configured to enable in response to a trigger, a pin, or a shifter condition.
- Updating the counter; Decrement always or only on a trigger or pin edge;
- Resetting the timer; Reset in response to a trigger or pin condition;
- Disabling the timer; Timer is disabled on a trigger, a pin condition, or on a timer comparison. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as a previous timer. For example, timer1 can enable or disable at the same time as timer 0 and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, a shifter status flag, a pin input or an external trigger input. The trigger configuration is separate from the pin configuration, which can be configured for input, output data, or output enable.

23.2.3 FlexIO HAL model building

In addition to setting global features and reading the information of hardware attribution, the most important APIs involve operating the timer and shifter. `FLEXIO_HAL_ConfigureTimer()` and `FLEXIO_HAL_ConfigureShifter()` functions are designed to configure the timer and shifter integrally with their related settings. There are also the APIs to enable/disable the interrupt/DMA, get/clear flags, fill/fetch the data to/from the shifter, in the same way as other drivers of bus interfaces.

As a basic driver of FlexIO module, the `flexio_hal` provides the basic APIs to operate the timer and shifter. To simulate the communication interface, the appropriate configuration should be applied. An SoC Reference Manual provides detailed information to use the `flexio_<device>_hal` which includes the special configurations with the basic FlexIO HAL driver.

Data Structures

- struct `flexio_timer_config_t`
Define structure of configuring the FlexIO timer. [More...](#)
- struct `flexio_shifter_config_t`
Define structure of configure the FlexIO shifter. [More...](#)

Enumerations

- enum `flexio_status_t` {
`kStatus_FLEXIO_Success` = 0U,
`kStatus_FLEXIO_InvalidArgument` = 1U,
`kStatus_FLEXIO_Failed` = 2U }
FlexIO status return code.
- enum `flexio_timer_trigger_polarity_t` {
`kFlexioTimerTriggerPolarityActiveHigh` = 0U,
`kFlexioTimerTriggerPolarityActiveLow` = 1U }
Define time of timer trigger polarity.
- enum `flexio_timer_trigger_source_t` {
`kFlexioTimerTriggerSourceExternal` = 0U,
`kFlexioTimerTriggerSourceInternal` = 1U }
Define type of timer trigger source.
- enum `flexio_pin_config_t` {
`kFlexioPinConfigOutputDisabled` = 0U,
`kFlexioPinConfigOpenDrainOrBidirection` = 1U,
`kFlexioPinConfigBidirectionOutputData` = 2U,
`kFlexioPinConfigOutput` = 3U }
Define type of timer/shifter pin configuration.
- enum `flexio_pin_polarity_t` {
`kFlexioPinActiveHigh` = 0U,
`kFlexioPinActiveLow` = 1U }
Definition of pin polarity.

FlexIO basic HAL Driver

- enum flexio_timer_mode_t {
 kFlexioTimerModeDisabled = 0U,
 kFlexioTimerModeDual8BitBaudBit = 1U,
 kFlexioTimerModeDual8BitPWM = 2U,
 kFlexioTimerModeSingle16Bit = 3U }
Define type of timer work mode.
- enum flexio_timer_output_t {
 kFlexioTimerOutputOneNotAffectedByReset = 0U,
 kFlexioTimerOutputZeroNotAffectedByReset = 1U,
 kFlexioTimerOutputOneAffectedByReset = 2U,
 kFlexioTimerOutputZeroAffectedByReset = 3U }
Define type of timer initial output or timer reset condition.
- enum flexio_timer_decrement_source_t {
 kFlexioTimerDecSrcOnFlexIOClockShiftTimerOutput = 0U,
 kFlexioTimerDecSrcOnTriggerInputShiftTimerOutput = 1U,
 kFlexioTimerDecSrcOnPinInputShiftPinInput = 2U,
 kFlexioTimerDecSrcOnTriggerInputShiftTriggerInput = 3U }
Define type of timer decrement.
- enum flexio_timer_reset_condition_t {
 kFlexioTimerResetNever = 0U,
 kFlexioTimerResetOnTimerPinEqualToTimerOutput = 2U,
 kFlexioTimerResetOnTimerTriggerEqualToTimerOutput = 3U,
 kFlexioTimerResetOnTimerPinRisingEdge = 4U,
 kFlexioTimerResetOnTimerTriggerRisingEdge = 6U,
 kFlexioTimerResetOnTimerTriggerBothEdge = 7U }
Define type of timer reset condition.
- enum flexio_timer_disable_condition_t {
 kFlexioTimerDisableNever = 0U,
 kFlexioTimerDisableOnPreTimerDisable = 1U,
 kFlexioTimerDisableOnTimerCompare = 2U,
 kFlexioTimerDisableOnTimerCompareTriggerLow = 3U,
 kFlexioTimerDisableOnPinBothEdge = 4U,
 kFlexioTimerDisableOnPinBothEdgeTriggerHigh = 5U,
 kFlexioTimerDisableOnTriggerFallingEdge = 6U }
Define type of timer disable condition.
- enum flexio_timer_enable_condition_t {
 kFlexioTimerEnabledAlways = 0U,
 kFlexioTimerEnableOnPrevTimerEnable = 1U,
 kFlexioTimerEnableOnTriggerHigh = 2U,
 kFlexioTimerEnableOnTriggerHighPinHigh = 3U,
 kFlexioTimerEnableOnPinRisingEdge = 4U,
 kFlexioTimerEnableOnPinRisingEdgeTriggerHigh = 5U,
 kFlexioTimerEnableOnTriggerRisingEdge = 6U,
 kFlexioTimerEnableOnTriggerBothEdge = 7U }
Define type of timer enable condition.
- enum flexio_timer_stop_bit_condition_t {

- ```

kFlexioTimerStopBitDisabled = 0U,
kFlexioTimerStopBitEnableOnTimerCompare = 1U,
kFlexioTimerStopBitEnableOnTimerDisable = 2U,
kFlexioTimerStopBitEnableOnTimerCompareDisable = 3U }

```
- Define type of timer stop bit generate condition.*
- enum flexio\_timer\_start\_bit\_condition\_t {

```

kFlexioTimerStartBitDisabled = 0U,
kFlexioTimerStartBitEnabled = 1U }

```

*Define type of timer start bit generate condition.*
  - enum flexio\_shifter\_timer\_polarity\_t

*Define type of timer polarity for shifter control.*
  - enum flexio\_shifter\_mode\_t {

```

kFlexioShifterDisabled = 0U,
kFlexioShifterModeReceive = 1U,
kFlexioShifterModeTransmit = 2U,
kFlexioShifterModeMatchStore = 4U,
kFlexioShifterModeMatchContinuous = 5U }

```

*Define type of shifter working mode.*
  - enum flexio\_shifter\_input\_source\_t {

```

kFlexioShifterInputFromPin = 0U,
kFlexioShifterInputFromNextShifterOutput = 1U }

```

*Define type of shifter input source.*
  - enum flexio\_shifter\_stop\_bit\_t {

```

kFlexioShifterStopBitDisable = 0U,
kFlexioShifterStopBitLow = 2U,
kFlexioShifterStopBitHigh = 3U }

```

*Define of STOP bit configuration.*
  - enum flexio\_shifter\_start\_bit\_t {

```

kFlexioShifterStartBitDisabledLoadDataOnEnable = 0U,
kFlexioShifterStartBitDisabledLoadDataOnShift = 1U,
kFlexioShifterStartBitLow = 2U,
kFlexioShifterStartBitHigh = 3U }

```

*Define type of START bit configuration.*

## Functions

- static uint32\_t **FLEXIO\_HAL\_GetMajorVersionNumber** (FLEXIO\_Type \*base)  
*Gets the FlexIO major version number.*
- static uint32\_t **FLEXIO\_HAL\_GetMinorVersionNumber** (FLEXIO\_Type \*base)  
*Gets the FlexIO minor version number.*
- static uint32\_t **FLEXIO\_HAL\_GetFeatureNumber** (FLEXIO\_Type \*base)  
*Gets the FlexIO feature specification number.*
- static uint32\_t **FLEXIO\_HAL\_GetTriggerNumber** (FLEXIO\_Type \*base)  
*Gets the number of implemented external triggers.*
- static uint32\_t **FLEXIO\_HAL\_GetPinNumber** (FLEXIO\_Type \*base)  
*Gets the number of implemented pins.*
- static uint32\_t **FLEXIO\_HAL\_GetTimerNumber** (FLEXIO\_Type \*base)

## FlexIO basic HAL Driver

- Gets the number of implemented timers.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterNumber](#) (FLEXIO\_Type \*base)
- Gets the number of implemented shifters.*

  - static void [FLEXIO\\_HAL\\_SetDozeModeCmd](#) (FLEXIO\_Type \*base, bool enable)
- Controls the FlexIO operation in doze modes.*

  - static void [FLEXIO\\_HAL\\_SetDebugModeCmd](#) (FLEXIO\_Type \*base, bool enable)
- Controls the FlexIO operation in debug mode.*

  - static void [FLEXIO\\_HAL\\_SetFastAccessCmd](#) (FLEXIO\_Type \*base, bool enable)
- Controls the FlexIO register accesses speed.*

  - static void [FLEXIO\\_HAL\\_SetSoftwareResetCmd](#) (FLEXIO\_Type \*base, bool enable)
- Software reset of the module.*

  - static void [FLEXIO\\_HAL\\_SetFlexioEnableCmd](#) (FLEXIO\_Type \*base, bool enable)
- Enables the FlexIO module operation.*

  - void [FLEXIO\\_HAL\\_SetTimerStatusIntCmd](#) (FLEXIO\_Type \*base, uint32\_t mask, bool enable)
- Enables or disables the timer status interrupt requests.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetTimerStatusFlags](#) (FLEXIO\_Type \*base)
- Gets timer status flags.*

  - static void [FLEXIO\\_HAL\\_ClearTimerStatusFlags](#) (FLEXIO\_Type \*base, uint32\_t mask)
- Clears timer status flags.*

  - void [FLEXIO\\_HAL\\_ConfigureTimer](#) (FLEXIO\_Type \*base, uint32\_t timerIdx, const [flexio\\_timer-\\_config\\_t](#) \*timerConfigPtr)
- Configures a FlexIO timer.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterStatusFlags](#) (FLEXIO\_Type \*base)
- Gets shifter status flags.*

  - static void [FLEXIO\\_HAL\\_ClearShifterStatusFlags](#) (FLEXIO\_Type \*base, uint32\_t mask)
- Clears shifter status flags.*

  - void [FLEXIO\\_HAL\\_SetShifterStatusIntCmd](#) (FLEXIO\_Type \*base, uint32\_t mask, bool enable)
- Enables or disables shifter status interrupt requests.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterStatusIntCmd](#) (FLEXIO\_Type \*base)
- Returns enabled shifter status interrupts.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterErrorFlags](#) (FLEXIO\_Type \*base)
- Gets shifter error flags.*

  - static void [FLEXIO\\_HAL\\_ClearShifterErrorFlags](#) (FLEXIO\_Type \*base, uint32\_t mask)
- Clears shifter error flags.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterErrorInt](#) (FLEXIO\_Type \*base)
- Returns shifter enabled error interrupts.*

  - void [FLEXIO\\_HAL\\_SetShifterErrorIntCmd](#) (FLEXIO\_Type \*base, uint32\_t mask, bool enable)
- Enables or disables shifter error interrupt requests.*

  - void [FLEXIO\\_HAL\\_ConfigureShifter](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx, const [flexio-\\_shifter\\_config\\_t](#) \*shifterConfigPtr)
- Configures a shifter including CTL and CFG.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShiftStatusDma](#) (FLEXIO\_Type \*base)
- Returns the shifter-enabled status DMA support.*

  - void [FLEXIO\\_HAL\\_SetShifterStatusDmaCmd](#) (FLEXIO\_Type \*base, uint32\_t mask, bool enable)
- Enables or disables the shifter status DMA support.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterBuffer](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx)
- Stores data from the shifter buffer.*

  - static void [FLEXIO\\_HAL\\_SetShifterBuffer](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx, uint32\_t value)
- Loads data to the shifter buffer.*

  - static uint32\_t [FLEXIO\\_HAL\\_GetShifterBufferBitByteSwapped](#) (FLEXIO\_Type \*base, uint32\_t

shifterIdx)

*Stores data from the bit byte swapped shifter buffer.*

- static void [FLEXIO\\_HAL\\_SetShifterBufferBitByteSwapped](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx, uint32\_t value)

*Loads data to the bit byte swapped shifter buffer.*

- static uint32\_t [FLEXIO\\_HAL\\_GetShifterBufferByteSwapped](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx)

*Stores data from the byte swapped shifter buffer.*

- static void [FLEXIO\\_HAL\\_SetShifterBufferByteSwapped](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx, uint32\_t value)

*Loads data to the byte swapped shifter buffer.*

- static uint32\_t [FLEXIO\\_HAL\\_GetShifterBufferBitSwapped](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx)

*Stores data from the bit swapped shifter buffer.*

- static void [FLEXIO\\_HAL\\_SetShifterBufferBitSwapped](#) (FLEXIO\_Type \*base, uint32\_t shifterIdx, uint32\_t value)

*Loads data to the bit swapped shifter buffer.*

- void [FLEXIO\\_HAL\\_Init](#) (FLEXIO\_Type \*base)

*Restores the FlexIO peripheral to reset state.*

## 23.2.4 Data Structure Documentation

### 23.2.4.1 struct flexio\_timer\_config\_t

## 23.2.5 Enumeration Type Documentation

### 23.2.5.1 `enum flexio_status_t`

Enumerator

*kStatus\_FLEXIO\_Success* Success.

*kStatus\_FLEXIO\_InvalidArgument* Invalid argument existed.

*kStatus\_FLEXIO\_Failed* Execution failed.

### 23.2.5.2 `enum flexio_timer_trigger_polarity_t`

Enumerator

*kFlexioTimerTriggerPolarityActiveHigh* Active high.

*kFlexioTimerTriggerPolarityActiveLow* Active low.

## FlexIO basic HAL Driver

### 23.2.5.3 enum flexio\_timer\_trigger\_source\_t

Enumerator

*kFlexioTimerTriggerSourceExternal* External trigger selected.

*kFlexioTimerTriggerSourceInternal* Internal trigger selected.

### 23.2.5.4 enum flexio\_pin\_config\_t

Enumerator

*kFlexioPinConfigOutputDisabled* Pin output disabled.

*kFlexioPinConfigOpenDrainOrBidirection* Pin open drain or bidirectional output enable.

*kFlexioPinConfigBidirectionOutputData* Pin bidirectional output data.

*kFlexioPinConfigOutput* Pin output.

### 23.2.5.5 enum flexio\_pin\_polarity\_t

Enumerator

*kFlexioPinActiveHigh* Active high.

*kFlexioPinActiveLow* Active low.

### 23.2.5.6 enum flexio\_timer\_mode\_t

Enumerator

*kFlexioTimerModeDisabled* Timer Disabled.

*kFlexioTimerModeDual8BitBaudBit* Dual 8-bit counters baud/bit mode.

*kFlexioTimerModeDual8BitPWM* Dual 8-bit counters PWM mode.

*kFlexioTimerModeSingle16Bit* Single 16-bit counter mode.

### 23.2.5.7 enum flexio\_timer\_output\_t

Enumerator

*kFlexioTimerOutputOneNotAffectedByReset* Logic one when enabled and is not affected by timer reset.

*kFlexioTimerOutputZeroNotAffectedByReset* Logic zero when enabled and is not affected by timer reset.

*kFlexioTimerOutputOneAffectedByReset* Logic one when enabled and on timer reset.

*kFlexioTimerOutputZeroAffectedByReset* Logic zero when enabled and on timer reset.

### 23.2.5.8 enum flexio\_timer\_decrement\_source\_t

Enumerator

- kFlexioTimerDecSrcOnFlexIOClockShiftTimerOutput* Decrement counter on FlexIO clock, Shift clock equals Timer output.
- kFlexioTimerDecSrcOnTriggerInputShiftTimerOutput* Decrement counter on Trigger input (both edges), Shift clock equals Timer output.
- kFlexioTimerDecSrcOnPinInputShiftPinInput* Decrement counter on Pin input (both edges), Shift clock equals Pin input.
- kFlexioTimerDecSrcOnTriggerInputShiftTriggerInput* Decrement counter on Trigger input (both edges), Shift clock equals Trigger input.

### 23.2.5.9 enum flexio\_timer\_reset\_condition\_t

Enumerator

- kFlexioTimerResetNever* Timer never reset.
- kFlexioTimerResetOnTimerPinEqualToTimerOutput* Timer reset on Timer Pin equal to Timer Output.
- kFlexioTimerResetOnTimerTriggerEqualToTimerOutput* Timer reset on Timer Trigger equal to Timer Output.
- kFlexioTimerResetOnTimerPinRisingEdge* Timer reset on Timer Pin rising edge.
- kFlexioTimerResetOnTimerTriggerRisingEdge* Timer reset on Trigger rising edge.
- kFlexioTimerResetOnTimerTriggerBothEdge* Timer reset on Trigger rising or falling edge.

### 23.2.5.10 enum flexio\_timer\_disable\_condition\_t

Enumerator

- kFlexioTimerDisableNever* Timer never disabled.
- kFlexioTimerDisableOnPreTimerDisable* Timer disabled on Timer N-1 disable.
- kFlexioTimerDisableOnTimerCompare* Timer disabled on Timer compare.
- kFlexioTimerDisableOnTimerCompareTriggerLow* Timer disabled on Timer compare and Trigger Low.
- kFlexioTimerDisableOnPinBothEdge* Timer disabled on Pin rising or falling edge.
- kFlexioTimerDisableOnPinBothEdgeTriggerHigh* Timer disabled on Pin rising or falling edge provided Trigger is high.
- kFlexioTimerDisableOnTriggerFallingEdge* Timer disabled on Trigger falling edge.

### 23.2.5.11 enum flexio\_timer\_enable\_condition\_t

Enumerator

- kFlexioTimerEnabledAlways* Timer always enabled.

## FlexIO basic HAL Driver

*kFlexioTimerEnableOnPrevTimerEnable* Timer enabled on Timer N-1 enable.

*kFlexioTimerEnableOnTriggerHigh* Timer enabled on Trigger high.

*kFlexioTimerEnableOnTriggerHighPinHigh* Timer enabled on Trigger high and Pin high.

*kFlexioTimerEnableOnPinRisingEdge* Timer enabled on Pin rising edge.

*kFlexioTimerEnableOnPinRisingEdgeTriggerHigh* Timer enabled on Pin rising edge and Trigger high.

*kFlexioTimerEnableOnTriggerRisingEdge* Timer enabled on Trigger rising edge.

*kFlexioTimerEnableOnTriggerBothEdge* Timer enabled on Trigger rising or falling edge.

### 23.2.5.12 enum flexio\_timer\_stop\_bit\_condition\_t

Enumerator

*kFlexioTimerStopBitDisabled* Stop bit disabled.

*kFlexioTimerStopBitEnableOnTimerCompare* Stop bit is enabled on timer compare.

*kFlexioTimerStopBitEnableOnTimerDisable* Stop bit is enabled on timer disable.

*kFlexioTimerStopBitEnableOnTimerCompareDisable* Stop bit is enabled on timer compare and timer disable.

### 23.2.5.13 enum flexio\_timer\_start\_bit\_condition\_t

Enumerator

*kFlexioTimerStartBitDisabled* Start bit disabled.

*kFlexioTimerStartBitEnabled* Start bit enabled.

### 23.2.5.14 enum flexio\_shifter\_timer\_polarity\_t

### 23.2.5.15 enum flexio\_shifter\_mode\_t

Enumerator

*kFlexioShifterDisabled* Shifter is disabled.

*kFlexioShifterModeReceive* Receive mode.

*kFlexioShifterModeTransmit* Transmit mode.

*kFlexioShifterModeMatchStore* Match store mode.

*kFlexioShifterModeMatchContinuous* Match continuous mode.

### 23.2.5.16 enum flexio\_shifter\_input\_source\_t

Enumerator

*kFlexioShifterInputFromPin* Shifter input from pin.

*kFlexioShifterInputFromNextShifterOutput* Shifter input from Shifter N+1.

### 23.2.5.17 enum flexio\_shifter\_stop\_bit\_t

Enumerator

- kFlexioShifterStopBitDisable* Disable shifter stop bit.
- kFlexioShifterStopBitLow* Set shifter stop bit to logic low level.
- kFlexioShifterStopBitHigh* Set shifter stop bit to logic high level.

### 23.2.5.18 enum flexio\_shifter\_start\_bit\_t

Enumerator

- kFlexioShifterStartBitDisabledLoadDataOnEnable* Disable shifter start bit, transmitter loads data on enable.
- kFlexioShifterStartBitDisabledLoadDataOnShift* Disable shifter start bit, transmitter loads data on first shift.
- kFlexioShifterStartBitLow* Set shifter start bit to logic low level.
- kFlexioShifterStartBitHigh* Set shifter start bit to logic high level.

## 23.2.6 Function Documentation

### 23.2.6.1 static uint32\_t FLEXIO\_HAL\_GetMajorVersionNumber ( FLEXIO\_Type \* base ) [inline], [static]

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

major version

### 23.2.6.2 static uint32\_t FLEXIO\_HAL\_GetMinorVersionNumber ( FLEXIO\_Type \* base ) [inline], [static]

Parameters

## FlexIO basic HAL Driver

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

minor version

**23.2.6.3** `static uint32_t FLEXIO_HAL_GetFeatureNumber ( FLEXIO_Type * base )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

feature number

**23.2.6.4** `static uint32_t FLEXIO_HAL_GetTriggerNumber ( FLEXIO_Type * base )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

number of external triggers

**23.2.6.5** `static uint32_t FLEXIO_HAL_GetPinNumber ( FLEXIO_Type * base )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

number of pins

**23.2.6.6** `static uint32_t FLEXIO_HAL_GetTimerNumber ( FLEXIO_Type * base )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

number of timers

**23.2.6.7** `static uint32_t FLEXIO_HAL_GetShifterNumber ( FLEXIO_Type * base )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

number of shifters

**23.2.6.8** `static void FLEXIO_HAL_SetDozeModeCmd ( FLEXIO_Type * base, bool enable )`  
`[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

## FlexIO basic HAL Driver

|               |                                           |
|---------------|-------------------------------------------|
| <i>enable</i> | Pass true to enable FlexIO in Doze modes. |
|---------------|-------------------------------------------|

**23.2.6.9** `static void FLEXIO_HAL_SetDebugModeCmd ( FLEXIO_Type * base, bool enable ) [inline], [static]`

Parameters

|               |                                           |
|---------------|-------------------------------------------|
| <i>base</i>   | base address                              |
| <i>enable</i> | Pass true to enable FlexIO in debug mode. |

**23.2.6.10** `static void FLEXIO_HAL_SetFastAccessCmd ( FLEXIO_Type * base, bool enable ) [inline], [static]`

Parameters

|               |                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | base address                                                                                                                                                     |
| <i>enable</i> | true if fast register access is enabled, FlexIO clock to be set at least twice the frequency of the bus clock. Or false if normal register accesses is selected. |

**23.2.6.11** `static void FLEXIO_HAL_SetSoftwareResetCmd ( FLEXIO_Type * base, bool enable ) [inline], [static]`

Parameters

|               |                                                           |
|---------------|-----------------------------------------------------------|
| <i>base</i>   | base address                                              |
| <i>enable</i> | true - Enable software reset false - Clear software reset |

**23.2.6.12** `static void FLEXIO_HAL_SetFlexioEnableCmd ( FLEXIO_Type * base, bool enable ) [inline], [static]`

Parameters

---

|               |                            |
|---------------|----------------------------|
| <i>base</i>   | base address               |
| <i>enable</i> | Pass true to enable FlexIO |

**23.2.6.13 void FLEXIO\_HAL\_SetTimerStatusIntCmd ( FLEXIO\_Type \* *base*, uint32\_t *mask*, bool *enable* )**

Parameters

|               |                                                        |
|---------------|--------------------------------------------------------|
| <i>base</i>   | base address                                           |
| <i>mask</i>   | Mask of timers to be enabled/disabled interrupt status |
| <i>enable</i> | Pass true to enable interrupt, false to disable        |

**23.2.6.14 static uint32\_t FLEXIO\_HAL\_GetTimerStatusFlags ( FLEXIO\_Type \* *base* ) [inline], [static]**

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

timer status flags

**23.2.6.15 static void FLEXIO\_HAL\_ClearTimerStatusFlags ( FLEXIO\_Type \* *base*, uint32\_t *mask* ) [inline], [static]**

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
| <i>mask</i> | timer mask   |

Returns

timer status flags

**23.2.6.16 void FLEXIO\_HAL\_ConfigureTimer ( FLEXIO\_Type \* *base*, uint32\_t *timerIdx*, const flexio\_timer\_config\_t \* *timerConfigPtr* )**

## FlexIO basic HAL Driver

### Parameters

|                       |                                              |
|-----------------------|----------------------------------------------|
| <i>base</i>           | base address                                 |
| <i>timerIdx</i>       | timer id number                              |
| <i>timerConfigPtr</i> | pointer to FlexIO's timer configuration data |

**23.2.6.17** `static uint32_t FLEXIO_HAL_GetShifterStatusFlags ( FLEXIO_Type * base )`  
`[inline], [static]`

### Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

### Returns

shifter status flags

**23.2.6.18** `static void FLEXIO_HAL_ClearShifterStatusFlags ( FLEXIO_Type * base,`  
`uint32_t mask ) [inline], [static]`

### Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
| <i>mask</i> | shifter mask |

### Returns

shifter status flags

**23.2.6.19** `void FLEXIO_HAL_SetShifterStatusIntCmd ( FLEXIO_Type * base, uint32_t`  
`mask, bool enable )`

### Parameters

---

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <i>base</i>   | base address                                                    |
| <i>mask</i>   | Mask of shifters to be enabled/disabled status interrupt status |
| <i>enable</i> | Pass true to enable interrupt, false to disable                 |

**23.2.6.20** `static uint32_t FLEXIO_HAL_GetShifterStatusIntCmd ( FLEXIO_Type * base ) [inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

mask - Mask of enabled shifter status interrupt

**23.2.6.21** `static uint32_t FLEXIO_HAL_GetShifterErrorFlags ( FLEXIO_Type * base ) [inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

shifter error flags

**23.2.6.22** `static void FLEXIO_HAL_ClearShifterErrorFlags ( FLEXIO_Type * base, uint32_t mask ) [inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
| <i>mask</i> | shifter mask |

## FlexIO basic HAL Driver

Returns

shifter error flags

**23.2.6.23** `static uint32_t FLEXIO_HAL_GetShifterErrorInt ( FLEXIO_Type * base )  
[inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

mask - Mask of enabled shifter error interrupt

**23.2.6.24** `void FLEXIO_HAL_SetShifterErrorIntCmd ( FLEXIO_Type * base, uint32_t  
mask, bool enable )`

Parameters

|               |                                                                |
|---------------|----------------------------------------------------------------|
| <i>base</i>   | base address                                                   |
| <i>mask</i>   | Mask of shifters to be enabled/disabled error interrupt status |
| <i>enable</i> | Pass true to enable interrupt, false to disable                |

**23.2.6.25** `void FLEXIO_HAL_ConfigureShifter ( FLEXIO_Type * base, uint32_t shifterIdx,  
const flexio_shifter_config_t * shifterConfigPtr )`

Parameters

|                   |               |
|-------------------|---------------|
| <i>base</i>       | base address  |
| <i>shifterIdx</i> | shifter index |

|                         |                                            |
|-------------------------|--------------------------------------------|
| <i>shifterConfigPtr</i> | pointer to shifter configuration structure |
|-------------------------|--------------------------------------------|

**23.2.6.26** `static uint32_t FLEXIO_HAL_GetShiftStatusDma ( FLEXIO_Type * base ) [inline], [static]`

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

Returns

mask Mask of shifters' DMA status

**23.2.6.27** `void FLEXIO_HAL_SetShifterStatusDmaCmd ( FLEXIO_Type * base, uint32_t mask, bool enable )`

Parameters

|               |                                                    |
|---------------|----------------------------------------------------|
| <i>base</i>   | base address                                       |
| <i>mask</i>   | Mask of shifters to be enabled/disabled DMA status |
| <i>enable</i> | Pass true to enable DMA transfer signalling        |

**23.2.6.28** `static uint32_t FLEXIO_HAL_GetShifterBuffer ( FLEXIO_Type * base, uint32_t shifterIdx ) [inline], [static]`

Parameters

|                   |               |
|-------------------|---------------|
| <i>base</i>       | base address  |
| <i>shifterIdx</i> | shifter index |

Returns

shifter buffer content

**23.2.6.29** `static void FLEXIO_HAL_SetShifterBuffer ( FLEXIO_Type * base, uint32_t shifterIdx, uint32_t value ) [inline], [static]`

## FlexIO basic HAL Driver

### Parameters

|                   |                                    |
|-------------------|------------------------------------|
| <i>base</i>       | base address                       |
| <i>shifterIdx</i> | shifter index                      |
| <i>value</i>      | Value to be load to shifter buffer |

**23.2.6.30** `static uint32_t FLEXIO_HAL_GetShifterBufferBitByteSwapped ( FLEXIO_Type *  
base, uint32_t shifterIdx ) [inline], [static]`

### Parameters

|                   |               |
|-------------------|---------------|
| <i>base</i>       | base address  |
| <i>shifterIdx</i> | shifter index |

### Returns

bit byte swapped shifter buffer content SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15],  
SHIFTBUF[0:7]

**23.2.6.31** `static void FLEXIO_HAL_SetShifterBufferBitByteSwapped ( FLEXIO_Type *  
base, uint32_t shifterIdx, uint32_t value ) [inline], [static]`

### Parameters

|                   |                                                     |
|-------------------|-----------------------------------------------------|
| <i>base</i>       | base address                                        |
| <i>shifterIdx</i> | shifter index                                       |
| <i>value</i>      | Value to be load to bit byte swapped shifter buffer |

**23.2.6.32** `static uint32_t FLEXIO_HAL_GetShifterBufferByteSwapped ( FLEXIO_Type *  
base, uint32_t shifterIdx ) [inline], [static]`

### Parameters

---

|                   |               |
|-------------------|---------------|
| <i>base</i>       | base address  |
| <i>shifterIdx</i> | shifter index |

Returns

bit byte swapped shifter buffer content SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]

**23.2.6.33** `static void FLEXIO_HAL_SetShifterBufferByteSwapped ( FLEXIO_Type * base, uint32_t shifterIdx, uint32_t value ) [inline], [static]`

Parameters

|                   |                                                 |
|-------------------|-------------------------------------------------|
| <i>base</i>       | base address                                    |
| <i>shifterIdx</i> | shifter index                                   |
| <i>value</i>      | Value to be load to byte swapped shifter buffer |

**23.2.6.34** `static uint32_t FLEXIO_HAL_GetShifterBufferBitSwapped ( FLEXIO_Type * base, uint32_t shifterIdx ) [inline], [static]`

Parameters

|                   |               |
|-------------------|---------------|
| <i>base</i>       | base address  |
| <i>shifterIdx</i> | shifter index |

Returns

bit swapped shifter buffer content SHIFTBUF[0:31]

**23.2.6.35** `static void FLEXIO_HAL_SetShifterBufferBitSwapped ( FLEXIO_Type * base, uint32_t shifterIdx, uint32_t value ) [inline], [static]`

Parameters

\_\_\_\_\_

## FlexIO basic HAL Driver

|                   |                                                |
|-------------------|------------------------------------------------|
| <i>base</i>       | base address                                   |
| <i>shifterIdx</i> | shifter index                                  |
| <i>value</i>      | Value to be load to bit swapped shifter buffer |

### 23.2.6.36 void FLEXIO\_HAL\_Init ( FLEXIO\_Type \* *base* )

Parameters

|             |              |
|-------------|--------------|
| <i>base</i> | base address |
|-------------|--------------|

## 23.3 FlexIO basic Peripheral Driver

### 23.3.1 Overview

This section describes the programming interface of the FlexIO basic Peripheral driver. The FlexIO basic peripheral driver configures the common features of FlexIO. It handles the common initialization, clock, and interrupts when using FlexIO.

### 23.3.2 FlexIO PD model building

The FlexIO module simulate the device and its life cycle corresponds to a life cycle of various simulated devices. These functions are implemented by the FlexIO simulated device drivers. However, before or after these life cycles, there are some common operations. FlexIO basic PD driver provides the APIs to set the FlexIO globally, such as enabling/disabling the clock/interrupt and starting/pausing the module.

Note that for complex simulations, such as the camera interface, it is recommended not to simulate more than one device at the same time. In the camera use case, the application may pause the camera's interface by stopping the FlexIO module calling the `FLEXIO_DRV_Pause()`, which may affect other simulated devices.

For FlexIO basic driver usage:

```
#include "fsl_flexio_driver.h"

const flexio_user_config_t FlexIOUserConfigStruct =
{
 .useInt = false,
 .onDozeEnable = false,
 .onDebugEnable = true,
 .fastAccessEnable = true
};

int main(void)
{
 //...

 FLEXIO_DRV_Init(0U, &FlexIOUserConfigStruct);
 FLEXIO_DRV_Start(0U);

 /* Do the FlexIO devices' simulation.
 //...
 {
 FLEXIO_DRV_Pause(0U);
 //...
 FLEXIO_DRV_Start(0U);

 }

 FLEXIO_DRV_Deinit(0U);

 return 0U;
}
```

## FlexIO basic Peripheral Driver

### Data Structures

- struct [flexio\\_user\\_config\\_t](#)  
*Defines the structure to configure the FlexIO module. [More...](#)*
- struct [flexio\\_shifter\\_callback\\_t](#)  
*Defines the structure to register the shifter callback and parameter. [More...](#)*

### Typedefs

- typedef void(\* [flexio\\_shifter\\_int\\_handler\\_t](#))(void \*param)  
*Shifter interrupt handler function type.*

### Variables

- FLEXIO\_Type \*const [g\\_flexioBase](#) []  
*Table of base addresses for FlexIO instances.*
- const IRQn\_Type [g\\_flexioIrqId](#) []  
*Table to save FlexIO IRQ enumeration numbers defined in the CMSIS header file.*

### FlexIO Driver

- [flexio\\_status\\_t FLEXIO\\_DRV\\_Init](#) (uint32\_t instance, const [flexio\\_user\\_config\\_t](#) \*userConfigPtr)  
*Initializes the FlexIO module before using the FlexIO module.*
- void [FLEXIO\\_DRV\\_Start](#) (uint32\_t instance)  
*Enables the FlexIO after configuring the FlexIO devices.*
- void [FLEXIO\\_DRV\\_Pause](#) (uint32\_t instance)  
*Disables the FlexIO during FlexIO device configuration.*
- void [FLEXIO\\_DRV\\_RegisterCallback](#) (uint32\_t instance, uint32\_t shifterId, [flexio\\_shifter\\_int\\_handler\\_t](#) shifterIntHandler, void \*param)  
*Registers the callback function into a shifter interrupt.*
- [flexio\\_status\\_t FLEXIO\\_DRV\\_Deinit](#) (uint32\_t instance)  
*Deinitializes the FlexIO module.*
- void [FLEXIO\\_DRV\\_IRQHandler](#) (uint32\_t instance)  
*IRQ handler for FlexIO.*

## 23.3.3 Data Structure Documentation

### 23.3.3.1 struct flexio\_user\_config\_t

#### Data Fields

- bool [useInt](#)  
*Enables supporting interrupts.*
- bool [onDozeEnable](#)  
*Controls the FlexIO operation in doze modes.*

- bool `onDebugEnabled`  
*Enables FlexIO operation when in debug mode.*
- bool `fastAccessEnable`

### 23.3.3.2 struct flexio\_shifter\_callback\_t

## 23.3.4 Function Documentation

### 23.3.4.1 flexio\_status\_t FLEXIO\_DRV\_Init ( uint32\_t instance, const flexio\_user\_config\_t \* userConfigPtr )

Parameters

|                      |                                         |
|----------------------|-----------------------------------------|
| <i>instance</i>      | FlexIO instance ID.                     |
| <i>userConfigPtr</i> | Pointer to the configuration structure. |

Returns

Execution status.

### 23.3.4.2 void FLEXIO\_DRV\_Start ( uint32\_t instance )

Parameters

|                 |                     |
|-----------------|---------------------|
| <i>instance</i> | FlexIO instance ID. |
|-----------------|---------------------|

### 23.3.4.3 void FLEXIO\_DRV\_Pause ( uint32\_t instance )

Parameters

|                 |                     |
|-----------------|---------------------|
| <i>instance</i> | FlexIO instance ID. |
|-----------------|---------------------|

### 23.3.4.4 void FLEXIO\_DRV\_RegisterCallback ( uint32\_t instance, uint32\_t shifterId, flexio\_shifter\_int\_handler\_t shifterIntHandler, void \* param )

## FlexIO basic Peripheral Driver

Parameters

|                           |                                     |
|---------------------------|-------------------------------------|
| <i>instance</i>           | FlexIO instance ID.                 |
| <i>shifterId</i>          | Index of shifter.                   |
| <i>shifterInt-Handler</i> | Callback function to be registered. |
| <i>param</i>              | Parameter for callback function.    |

### 23.3.4.5 flexio\_status\_t FLEXIO\_DRV\_Deinit ( uint32\_t instance )

Parameters

|                 |                     |
|-----------------|---------------------|
| <i>instance</i> | FlexIO instance ID. |
|-----------------|---------------------|

Returns

Execution status.

### 23.3.4.6 void FLEXIO\_DRV\_IRQHandler ( uint32\_t instance )

Parameters

|                 |                     |
|-----------------|---------------------|
| <i>instance</i> | FlexIO instance ID. |
|-----------------|---------------------|

## Chapter 24

### FlexIO-simulated Camera (FlexIO\_Camera)

#### 24.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the camera interface simulated by FlexIO. The FlexIO-simulated camera is only available when the FlexIO module has a parallel mode supported, such as on Kinetis 80 SoCs.

#### Modules

- [FlexIO\\_Camera HAL Driver](#)
- [FlexIO\\_Camera\\_EDMA Peripheral Driver](#)

## FlexIO\_Camera HAL Driver

### 24.2 FlexIO\_Camera HAL Driver

This section describes the programming interface of the FlexIO Camera HAL driver.

#### 24.2.1 FlexIO Camera HAL description

The FlexIO Camera HAL supports the general 8-bit Camera Parallel Interface (CPI) for camera devices, such as the OV7670.

The FlexIO Camera Interface is simulated from the FlexIO basic HAL driver using one timer, multiple shifters (typically 8 count, such as the data buffer) and ten pins (eight pins for data D[0..7], one pin for PCLK, and one pin for HREF). The HREF pin signal triggers the timer. The PCLK pin signal drives the timer's counter and the shifter. Finally, the data pin signals are shifted into the shifter's chain buffer, where each shifter is connected to one another. Multiple transfers from the buffer to the indicated memory can be supported using the external DMA controller.

Note that the FlexIO Camera driver covers the data bus interface. Additionally, to connect the driver to the camera, the SCCB bus and a VSYNC signal need to be implemented in the application. The SCCB bus is compatible with I2C hardware. The VSYNC signal can be implemented using the GPIO's IRQ, which is more flexible for the application.

#### Usage of FlexIO Camera HAL

This is an example that shows how to use the FlexIO Camera Interface to capture the image data from an OV7670 camera and display it to an LCD module with FlexBus interface. The triggers for Camera DMA and LCD DMA are generated by the buffer full event.

```
#include "fsl_flexio_hal.h"
#include "fsl_flexio_camera.h"
#include "fsl_edma_hal.h"

// FlexIO configuration structures.

## FlexIO\_Camera\_EDMA Peripheral Driver

### 24.3 FlexIO\_Camera\_EDMA Peripheral Driver

This section describes the programming interface of the FlexIO Camera with eDMA Peripheral driver.

#### 24.3.1 FlexIO Camera with eDMA Peripheral Driver description

FlexIO Camera with eDMA provides a use case that shows how to map the image data from the camera's sensor matrix to the indicated memory area. In this module, a DMA channel inside the driver syncs the data from the camera to memory automatically in the background. The DMA channel is triggered after the FlexIO Camera's buffer is filled and updates the data for every trigger. In this instance, the the internal DMA and camera's data stream are not relevant to the application. The application reads the mapped image data as soon as possible with no blocking. Reading the memory corresponds to reading the camera's sensor matrix directly.

Note that, when using DMA to transfer data, because of the cache for memory, the data must be consistent. This means that, when reading data from memory, the application must ensure that data from or to the memory device is not cached.

#### Usage of FlexIO Camera with eDMA Peripheral Driver

```
#include "fsl_edma_driver.h"
#include "fsl_flexio_camera_edma_driver.h"
#include "fsl_flexio_driver.h"

## Chapter 25

### FlexIO-simulated I2C (FlexIO\_I2C)

#### 25.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for using FlexIO to simulate I2C (FlexIO\_I2C) on the FlexIO block of Kinetis devices.

#### Modules

- [FlexIO I2C HAL driver](#)
- [FlexIO I2C Master peripheral driver](#)

## FlexIO I2C HAL driver

### 25.2 FlexIO I2C HAL driver

#### 25.2.1 Overview

This section describes the programming interface of the FlexIO I2C HAL driver.

#### Data Structures

- struct `flexio_i2c_dev_t`  
*Define structure of configuring the flexio i2c device. [More...](#)*
- struct `flexio_i2c_master_config_t`  
*Define structure of configuring the flexio i2c bus for master. [More...](#)*

#### Functions

- `flexio_status_t FLEXIO_I2C_HAL_ConfigMaster` (`flexio_i2c_dev_t *devPtr`, `const flexio_i2c_master_config_t *configPtr`)  
*Configure the flexio working as i2c master device.*
- `flexio_status_t FLEXIO_I2C_HAL_ConfigXferWordCountOnce` (`flexio_i2c_dev_t *devPtr`, `uint32_t count`)  
*Configure the count of words for each frame.*
- `bool FLEXIO_I2C_HAL_GetTxBufferEmptyFlag` (`flexio_i2c_dev_t *devPtr`)  
*Get the flag if the rx buffer is empty.*
- `void FLEXIO_I2C_HAL_ClearTxBufferEmptyFlag` (`flexio_i2c_dev_t *devPtr`)  
*Clear the flag of tx buffer empty manually.*
- `void FLEXIO_I2C_HAL_SetTxBufferEmptyIntCmd` (`flexio_i2c_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for tx buffer is empty.*
- `bool FLEXIO_I2C_HAL_GetTxErrFlag` (`flexio_i2c_dev_t *devPtr`)  
*Get the tx error flag.*
- `void FLEXIO_I2C_HAL_ClearTxErrFlag` (`flexio_i2c_dev_t *devPtr`)  
*Clear the tx error flag manually.*
- `void FLEXIO_I2C_HAL_SetTxErrIntCmd` (`flexio_i2c_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for tx error.*
- `void FLEXIO_I2C_HAL_PutData` (`flexio_i2c_dev_t *devPtr`, `uint32_t dat`)  
*Put data into tx buffer.*
- `void FLEXIO_I2C_HAL_PutDataPolling` (`flexio_i2c_dev_t *devPtr`, `uint32_t dat`)  
*Put data into tx buffer when empty.*
- `void FLEXIO_I2C_HAL_SetTxDmaCmd` (`flexio_i2c_dev_t *devPtr`, `bool enable`)  
*Switch on/off the tx DMA support.*
- `uint32_t FLEXIO_I2C_HAL_GetTxBufferAddr` (`flexio_i2c_dev_t *devPtr`)  
*Get address of tx buffer when using DMA.*
- `bool FLEXIO_I2C_HAL_GetRxBufferFullFlag` (`flexio_i2c_dev_t *devPtr`)  
*Get the flag that rx buffer is full.*
- `void FLEXIO_I2C_HAL_ClearRxBufferFullFlag` (`flexio_i2c_dev_t *devPtr`)  
*Clear the rx buffer empty flag manually.*
- `void FLEXIO_I2C_HAL_SetRxBufferFullIntCmd` (`flexio_i2c_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for rx buffer is full.*
- `bool FLEXIO_I2C_HAL_GetRxErrFlag` (`flexio_i2c_dev_t *devPtr`)

- Get the rx error flag.*

  - void [FLEXIO\\_I2C\\_HAL\\_ClearRxErrFlag](#) (flexio\_i2c\_dev\_t \*devPtr)

*Clear the rx error flag manually.*

  - void [FLEXIO\\_I2C\\_HAL\\_SetRxErrIntCmd](#) (flexio\_i2c\_dev\_t \*devPtr, bool enable)

*Switch on/off the interrupt for rx error.*

  - uint32\_t [FLEXIO\\_I2C\\_HAL\\_GetData](#) (flexio\_i2c\_dev\_t \*devPtr)

*Get the data from tx buffer.*

  - uint32\_t [FLEXIO\\_I2C\\_HAL\\_GetDataPolling](#) (flexio\_i2c\_dev\_t \*devPtr)

*Get the data from tx buffer when full.*

  - void [FLEXIO\\_I2C\\_HAL\\_SetRxDmaCmd](#) (flexio\_i2c\_dev\_t \*devPtr, bool enable)

*Switch on/off the rx DMA support.*

  - uint32\_t [FLEXIO\\_I2C\\_HAL\\_GetRxBufferAddr](#) (flexio\_i2c\_dev\_t \*devPtr)

*Get the address the of rx buffer.*

  - void [FLEXIO\\_I2C\\_HAL\\_ConfigSendNAck](#) (flexio\_i2c\_dev\_t \*devPtr)

*Configure the next sending would generate NACK condition.*

  - void [FLEXIO\\_I2C\\_HAL\\_ConfigSendAck](#) (flexio\_i2c\_dev\_t \*devPtr)

*Configure the next sending would generate ACK condition.*

## 25.2.2 Data Structure Documentation

### 25.2.2.1 struct flexio\_i2c\_dev\_t

#### Data Fields

- FLEXIO\_Type \* [flexioBase](#)  
*FlexIO module base pointer.*
- uint32\_t [sdaPinIdx](#)  
*Pin index for I2C SDA in FlexIO.*

25.2.2.2.0.108.3 **uint32\_t** flexio\_i2c\_master\_config\_t::xferWordCount

## 25.2.3 Function Documentation

**25.2.3.1 flexio\_status\_t FLEXIO\_I2C\_HAL\_ConfigMaster ( flexio\_i2c\_dev\_t \* devPtr, const flexio\_i2c\_master\_config\_t \* configPtr )**

Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>devPtr</i>    | Pointer to the device.              |
| <i>configPtr</i> | Pointer to configuration structure. |

Returns

Execution status.

**25.2.3.2 flexio\_status\_t FLEXIO\_I2C\_HAL\_ConfigXferWordCountOnce ( flexio\_i2c\_dev\_t \* devPtr, uint32\_t count )**

When using flexio\_i2c\_master, each frame's length should be configured before sending any word. Of course, when calling the [FLEXIO\\_I2C\\_HAL\\_ConfigMaster\(\)](#), user can set the "configPtr->xferWrod-Count" to set word count. However, this API could provide the light-weight setting without changing any other settings.

Parameters

|               |                            |
|---------------|----------------------------|
| <i>devPtr</i> | Pointer to the device.     |
| <i>count</i>  | Word count for each frame. |

Returns

Execution status.

**25.2.3.3 bool FLEXIO\_I2C\_HAL\_GetTxBufferEmptyFlag ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**25.2.3.4 void FLEXIO\_I2C\_HAL\_ClearTxBufferEmptyFlag ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

## FlexIO I2C HAL driver

**25.2.3.5 void FLEXIO\_I2C\_HAL\_SetTxBufferEmptyIntCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**25.2.3.6 bool FLEXIO\_I2C\_HAL\_GetTxErrFlag ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**25.2.3.7 void FLEXIO\_I2C\_HAL\_ClearTxErrFlag ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**25.2.3.8 void FLEXIO\_I2C\_HAL\_SetTxErrIntCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**25.2.3.9 void FLEXIO\_I2C\_HAL\_PutData ( flexio\_i2c\_dev\_t \* devPtr, uint32\_t dat )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

**25.2.3.10 void FLEXIO\_I2C\_HAL\_PutDataPolling ( flexio\_i2c\_dev\_t \* devPtr, uint32\_t dat )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

**25.2.3.11 void FLEXIO\_I2C\_HAL\_SetTxDmaCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**25.2.3.12 uint32\_t FLEXIO\_I2C\_HAL\_GetTxBufferAddr ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Address of tx buffer.

**25.2.3.13 bool FLEXIO\_I2C\_HAL\_GetRxBufferFullFlag ( flexio\_i2c\_dev\_t \* devPtr )**

## FlexIO I2C HAL driver

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Assertion of the event.

### 25.2.3.14 void FLEXIO\_I2C\_HAL\_ClearRxBufferFullFlag ( flexio\_i2c\_dev\_t \* devPtr )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 25.2.3.15 void FLEXIO\_I2C\_HAL\_SetRxBufferFullIntCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 25.2.3.16 bool FLEXIO\_I2C\_HAL\_GetRxErrFlag ( flexio\_i2c\_dev\_t \* devPtr )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Assertion of the event.

### 25.2.3.17 void FLEXIO\_I2C\_HAL\_ClearRxErrFlag ( flexio\_i2c\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**25.2.3.18 void FLEXIO\_I2C\_HAL\_SetRxErrIntCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**25.2.3.19 uint32\_t FLEXIO\_I2C\_HAL\_GetData ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from rx buffer.

**25.2.3.20 uint32\_t FLEXIO\_I2C\_HAL\_GetDataPolling ( flexio\_i2c\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from rx buffer.

**25.2.3.21 void FLEXIO\_I2C\_HAL\_SetRxDmaCmd ( flexio\_i2c\_dev\_t \* devPtr, bool enable )**

## FlexIO I2C HAL driver

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 25.2.3.22 uint32\_t FLEXIO\_I2C\_HAL\_GetRxBufferAddr ( flexio\_i2c\_dev\_t \* devPtr )

#### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

#### Returns

Address of rx buffer.

### 25.2.3.23 void FLEXIO\_I2C\_HAL\_ConfigSendNAck ( flexio\_i2c\_dev\_t \* devPtr )

#### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 25.2.3.24 void FLEXIO\_I2C\_HAL\_ConfigSendAck ( flexio\_i2c\_dev\_t \* devPtr )

#### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

## 25.3 FlexIO I2C Master peripheral driver

### 25.3.1 Overview

This section describes the programming interface of the FlexIO I2C master mode peripheral driver. The FlexIO I2C master peripheral driver provides functions for a master device to send and receive data.

### 25.3.2 FlexIO I2C Device structures

The driver uses an instantiation of the `flexio_i2c_state_t` structure to maintain the current state of a particular FlexIO-simulated I2C master driver. This structure holds data that is used by the FlexIO-simulated I2C master peripheral driver to communicate between the transmit and receive transfer functions and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. Because the driver itself does not statically allocate memory, the caller provides memory for the driver state structure during initialization by providing a structure.

### 25.3.3 FlexIO I2C user configuration structures

The FlexIO-simulated I2C driver uses instances of the user configuration structure `flexio_i2c_userconfig_t` for the FlexIO-simulated I2C driver. The user settings include: I2C mode(master or slave), baud rate, and the associated FlexIO timers, shifters, and pins for SDA and SCL.

### 25.3.4 FlexIO I2C Master Initialization

1. To initialize the FlexIO I2C Master driver, call the `FLEXIO_I2C_DRV_MasterInit()` function and pass the instance number of the FlexIO peripheral, memory for the run-time state structure, and a pointer to the user configuration structure. For example, to use FlexIO0 pass a value of 0 to the initialization function.
2. Then, pass the memory for the run-time state structure.
3. Finally, pass a user configuration structure of the type `flexio_i2c_userconfig_t` as shown here:

```
// FlexIO I2C Master configuration structure
typedef struct flexio_i2c_userconfig{
 uint32_t baudRate;
 flexio_i2c_hwconfig_t i2cHwConfig;
}flexio_i2c_userconfig_t;
```

The `flexio_i2c_userconfig` instantiation can be easily modified to configure the FlexIO I2C master peripheral driver either to a different baud rate or using different FlexIO hardware resource. This is an example code to set up a user FlexIO I2C master configuration instantiation:

```
flexio_i2c_userconfig_t i2cMasterConfig;
i2cMasterConfig.baudRate = 100000;
i2cMasterConfig.i2cHwConfig.sdaPinIdx = 0;
```

## FlexIO I2C Master peripheral driver

```
i2cMasterConfig.i2cHwConfig.sclkPinIdx = 1;
i2cMasterConfig.i2cHwConfig.shifterIdx[0] = 0;
i2cMasterConfig.i2cHwConfig.shifterIdx[1] = 1;
i2cMasterConfig.i2cHwConfig.timerIdx[0] = 0;
i2cMasterConfig.i2cHwConfig.timerIdx[1] = 1;
```

This example shows how to call the `FLEXIO_I2C_DRV_MasterInit()` given the user configuration structure and the FlexIO instance 0.

```
uint32_t flexioInstance = 0;
flexio_i2c_state_t i2cState; // user provides memory for the driver state structure

FLEXIO_I2C_DRV_MasterInit(flexioInstance, &i2cState, &i2cMasterConfig);
```

### 25.3.5 FlexIO I2C Master Data Transactions

The driver implements transmit and receive functions to transfer buffers of data in blocking and non-blocking modes.

The non-blocking transmit and receive functions include the `FLEXIO_I2C_DRV_MasterSendData()` and `FLEXIO_I2C_DRV_MasterReceiveData()` functions.

The blocking (async) transmit and receive functions include the `FLEXIO_I2C_DRV_MasterSendDataBlocking()` and `FLEXIO_I2C_DRV_MasterReceiveDataBlocking()` functions.

In all cases mentioned here, the functions are interrupt-driven.

This code example show how to use the functions, assuming that the FlexIO-simulated I2C Master module has been initialized as described previously in the Initialization Section.

This is an example code for blocking transfer functions transmit and receive:

```
uint8_t sourceBuff[26] = {0}; // sourceBuff can be filled out with desired data
uint8_t readBuffer[10] = {0}; // readBuffer gets filled

uint32_t byteCount = sizeof(sourceBuff);
uint32_t rxRemainingSize = sizeof(readBuffer);

// For each use there, set timeout as "1"
// i2cState is the run-time state. Pass in memory for this
// declared previously in the initialization chapter
FLEXIO_I2C_DRV_MasterSendDataBlocking(i2cState, sourceBuff, byteCount,
 1); // Function won't return until transmit is complete
FLEXIO_I2C_DRV_MasterReceiveDataBlocking(i2cState, readBuffer, 1,
 timeoutValue); // Function won't return until it receives all data
```

This is an example code for non-blocking (async) transfer functions transmit and receive:

```
uint8_t *pTxBuff;
uint8_t rxBuff[10];
uint32_t txBytesRemaining, rxBytesRemaining;

// Assume pTxBuff and txSize have been initialized
FLEXIO_I2C_DRV_MasterSendData(i2cState, pTxBuff, txSize);

// Check on status of transmit and wait until done; The code can do something else and
```

```
// check back later
while (FLEXIO_I2C_DRV_MasterGetTransmitStatus(i2cState, &
 txBytesRemaining) == kStatus_FlexIO_I2C_XBusy);

// To receive, assume rxBuff is set up to receive data and rxSize is initialized
FLEXIO_I2C_DRV_MasterReceiveData(i2cState, rxBuff, rxSize);

// Check on receive status and wait until done; The code can do something else and
// check back later
while (FLEXIO_I2C_DRV_MasterGetReceiveStatus(i2cState, &
 rxBytesRemaining) == kStatus_FlexIO_I2C_XBusy);
```

### Data Structures

- struct `flexio_i2c_memrequest_t`  
*Structure for write/read data from a specific memory address. [More...](#)*
- struct `flexio_i2c_state_t`  
*Runtime state structure for FlexIO I2C driver. [More...](#)*

### 25.3.6.2.0.109 Field Documentation

25.3.6.2.0.109.1 `flexio_i2c_dev_t flexio_i2c_state_t::i2cDev`

25.3.6.2.0.109.2 `volatile bool flexio_i2c_state_t::isXBusy`

25.3.6.2.0.109.3 `volatile bool flexio_i2c_state_t::isXBlocking`

25.3.6.2.0.109.4 `semaphore_t flexio_i2c_state_t::xIrqSync`

25.3.6.2.0.109.5 `flexio_i2c_rx_callback_t flexio_i2c_state_t::rxCallback`

25.3.6.2.0.109.6 `void* flexio_i2c_state_t::rxCallbackParam`

25.3.6.2.0.109.7 `volatile bool flexio_i2c_state_t::isTxUseDma`

25.3.6.2.0.109.8 `volatile bool flexio_i2c_state_t::isRxUseDma`

### 25.3.6.3 struct flexio\_i2c\_hwconfig\_t

These constants define the hardware resource used by FlexIO I2C master/slave device and include the external pin and internal shifter and timer.

#### Data Fields

- `uint32_t sdaPinIdx`  
*Data line.*
- `uint32_t sclkPinIdx`  
*Clock line.*
- `uint32_t shifterIdx` [2]  
*Shifter 0 is for transmit and shifter 1 is for receive.*
- `uint32_t timerIdx` [2]  
*Timer 0 is used to generate clock for clock line.*

### 25.3.6.3.0.110 Field Documentation

25.3.6.3.0.110.1 `uint32_t flexio_i2c_hwconfig_t::timerIdx[2]`

timer 1 is used to shift shifter

## FlexIO I2C Master peripheral driver

### 25.3.6.4 struct flexio\_i2c\_userconfig\_t

Use an instance of this structure with the FLEXIO\_I2C\_DRV\_Init()function. This enables configuration of the settings of the FlexIO I2C peripheral with a single function call. Settings include: I2C baud rate, data size, FlexIO I2C mode and FlexIO hardware resource resource.

#### Data Fields

- uint32\_t [baudRate](#)  
*Baudrate configuration.*
- [flexio\\_i2c\\_hwconfig\\_t i2cHwConfig](#)  
*FlexIO I2C Master Resource configuration.*

### 25.3.7 Enumeration Type Documentation

#### 25.3.7.1 enum flexio\_i2c\_status\_t

#### 25.3.7.2 enum flexio\_i2c\_direction\_t

Enumerator

*kFlexIOI2CWrite* Master transmit, slave receive.

*kFlexIOI2CRead* Master receive, slave transmit.

### 25.3.8 Function Documentation

#### 25.3.8.1 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterInit ( uint32\_t *instance*, flexio\_i2c\_state\_t \* *i2cState*, const flexio\_i2c\_userconfig\_t \* *i2cMasterConfig* )

This function initializes the run-time state structure to keep track of the on-going transfers and the module to user defined settings and default settings. It also configures the underlying FlexIO pin, shifter, and timer. This is an example to set up the [flexio\\_i2c\\_state\\_t](#) and the [flexio\\_i2c\\_userconfig\\_t](#) parameters and to call the FLEXIO\_I2C\_DRV\_Init function

```
flexio_i2c_userconif_t i2cMasterConfig;
i2cMasterConfig.baudRate = 100000;
i2cMasterConfig.i2cHwConfig.sdaPinIdx = 0;
i2cMasterConfig.i2cHwConfig.sclPinIdx = 1;
i2cMasterConfig.i2cHwConfig.shifterIdx = {0,1};
i2cMasterConfig.i2cHwConfig.timerIdx = {0,1};
```

### Parameters

|                         |                                                                                                                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>         | The FlexIO instance number.                                                                                                                                                                                                                                   |
| <i>i2cState</i>         | A pointer to the global FlexIO I2C driver state structure memory. The user passes in the memory for the run-time state structure. The FlexIO I2C driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>i2cMaster-Config</i> | The user configuration structure of type <a href="#">flexio_i2c_userconfig_t</a> . The user populates the members of this structure and passes the pointer of this structure to this function.                                                                |

### Returns

An error code or `kStatus_FlexIO_I2C_Success`.

### 25.3.8.2 void FLEXIO\_I2C\_DRV\_MasterDeinit ( flexio\_i2c\_state\_t \* i2cState )

This function disables the FlexIO-simulated I2C trigger.

### Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>i2cState</i> | The run-time structure of FlexIO-simulated I2C. |
|-----------------|-------------------------------------------------|

### 25.3.8.3 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterSendDataBlocking ( flexio\_i2c\_state\_t \* i2cState, uint16\_t slaveAddr, flexio\_i2c\_memrequest\_t \* memRequest, uint8\_t \* txBuff, uint32\_t txSize, uint32\_t timeout )

### Parameters

|                   |                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>   | The run-time structure of FlexIO-simulated I2C.                                                                             |
| <i>slaveAddr</i>  | 7-bit or 10-bit slave address.                                                                                              |
| <i>memRequest</i> | The memory request structure, including memory address and size, if the operation is not a memory request, could pass NULL. |
| <i>txBuff</i>     | A pointer to the source buffer containing 8-bit data chars to send.                                                         |
| <i>txSize</i>     | The number of bytes to send.                                                                                                |
| <i>timeout</i>    | A timeout value for RTOS abstraction sync control in milliseconds (ms).                                                     |

## FlexIO I2C Master peripheral driver

### Returns

An error code or `kStatus_FlexIO_I2C_Success`.

**25.3.8.4** `flexio_i2c_status_t FLEXIO_I2C_DRV_MasterSendData ( flexio_i2c_state_t * i2cState, uint16_t slaveAddr, flexio_i2c_memrequest_t * memRequest, uint8_t * txBuff, uint32_t txSize )`

### Parameters

|                   |                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>   | The run-time structure of FlexIO-simulated I2C.                                                                            |
| <i>slaveAddr</i>  | 7-bit or 10-bit slave address.                                                                                             |
| <i>memRequest</i> | The memory requests the structure, including memory address and size. If the operation is not a memory request, pass NULL. |
| <i>txBuff</i>     | A pointer to the source buffer containing 8-bit data chars to send.                                                        |
| <i>txSize</i>     | The number of bytes to send.                                                                                               |

### Returns

An error code or `kStatus_FlexIO_I2C_Success`.

**25.3.8.5** `flexio_i2c_status_t FLEXIO_I2C_DRV_MasterSendAddress ( flexio_i2c_state_t * i2cState, uint16_t slaveAddr, flexio_i2c_direction_t direction, flexio_i2c_memrequest_t * memRequest )`

### Parameters

|                   |                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>   | The run-time structure of FlexIO-simulated I2C.                                                                            |
| <i>direction</i>  | The direction of I2C operation, Read or Write.                                                                             |
| <i>slaveAddr</i>  | 7-bit or 10-bit slave address.                                                                                             |
| <i>memRequest</i> | The memory requests the structure, including memory address and size. If the operation is not a memory request, pass NULL. |

Returns

An error code or `kStatus_FlexIO_I2C_Success`.

**25.3.8.6 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterGetTransmitStatus ( flexio\_i2c\_state\_t \* *i2cState*, uint32\_t \* *bytesRemaining* )**

Parameters

|                       |                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>       | The run-time structure of FlexIO-simulated I2C.                                                            |
| <i>bytesRemaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

Returns

An error code or `kStatus_FlexIO_I2C_Success`.

Return values

|                                   |                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_I2C_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_I2C_Tx-Busy</i> | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

**25.3.8.7 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterAbortSendingData ( flexio\_i2c\_state\_t \* *i2cState* )**

Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>i2cState</i> | The run-time structure of FlexIO-simulated I2C. |
|-----------------|-------------------------------------------------|

Returns

An error code or `kStatus_FlexIO_I2C_Success`.

## FlexIO I2C Master peripheral driver

### Return values

|                                                |                                           |
|------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_I2C_Success</i>              | The transmit was successful.              |
| <i>kStatus_FlexIO_I2C_NoTransmitInProgress</i> | No transmission is currently in progress. |

### 25.3.8.8 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterReceiveDataBlocking ( flexio\_i2c\_state\_t \* *i2cState*, uint16\_t *slaveAddr*, flexio\_i2c\_memrequest\_t \* *memRequest*, uint8\_t \* *rxBuff*, uint32\_t *rxSize*, uint32\_t *timeout* )

#### Parameters

|                   |                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>   | The run-time structure of FlexIO-simulated I2C.                                                                            |
| <i>slaveAddr</i>  | 7-bit or 10-bit slave address.                                                                                             |
| <i>memRequest</i> | The memory requests the structure, including memory address and size. If the operation is not a memory request, pass NULL. |
| <i>rxBuff</i>     | A pointer to the buffer containing 8-bit read data chars received.                                                         |
| <i>rxSize</i>     | The number of bytes to receive.                                                                                            |
| <i>timeout</i>    | A timeout value for RTOS abstraction sync control in milliseconds (ms).                                                    |

#### Returns

An error code or *kStatus\_FlexIO\_I2C\_Success*.

### 25.3.8.9 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterReceiveData ( flexio\_i2c\_state\_t \* *i2cState*, uint16\_t *slaveAddr*, flexio\_i2c\_memrequest\_t \* *memRequest*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* )

#### Parameters

|                  |                                                 |
|------------------|-------------------------------------------------|
| <i>i2cState</i>  | The run-time structure of FlexIO-simulated I2C. |
| <i>slaveAddr</i> | 7-bit or 10-bit slave address.                  |

|                   |                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>memRequest</i> | The memory requests the structure, including memory address and size. If the operation is not a memory request, pass NULL. |
| <i>rxBuff</i>     | A pointer to the buffer containing 8-bit read data chars received.                                                         |
| <i>rxSize</i>     | The number of bytes to receive.                                                                                            |

Returns

An error code or `kStatus_FlexIO_I2C_Success`.

### 25.3.8.10 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterGetReceiveStatus ( flexio\_i2c\_state\_t \* *i2cState*, uint32\_t \* *bytesRemaining* )

Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>i2cState</i>        | The run-time structure of FlexIO-simulated I2C.                                                                         |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

Returns

An error code or `kStatus_FlexIO_I2C_Success`.

Return values

|                                    |                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_I2C_-Success</i> | The receive has completed successfully.                                                                                        |
| <i>kStatus_FlexIO_I2C_Rx-Busy</i>  | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

### 25.3.8.11 flexio\_i2c\_status\_t FLEXIO\_I2C\_DRV\_MasterAbortReceivingData ( flexio\_i2c\_state\_t \* *i2cState* )

Parameters

## FlexIO I2C Master peripheral driver

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>i2cState</i> | The run-time structure of FlexIO-simulated I2C. |
|-----------------|-------------------------------------------------|

Returns

An error code or `kStatus_I2C_Success`.

Return values

|                                                |                                      |
|------------------------------------------------|--------------------------------------|
| <i>kStatus_FlexIO_I2C_Success</i>              | The receive was successful.          |
| <i>kStatus_FlexIO_I2C_NoTransmitInProgress</i> | No receive is currently in progress. |

### 25.3.8.12 void FLEXIO\_I2C\_DRV\_TX\_IRQHandler ( void \* *param* )

Parameters

|              |                                                 |
|--------------|-------------------------------------------------|
| <i>param</i> | The run-time structure of FlexIO simulated I2C. |
|--------------|-------------------------------------------------|

### 25.3.8.13 void FLEXIO\_I2C\_DRV\_RX\_IRQHandler ( void \* *param* )

Parameters

|              |                                                 |
|--------------|-------------------------------------------------|
| <i>param</i> | The run-time structure of FlexIO simulated I2C. |
|--------------|-------------------------------------------------|

## Chapter 26

### FlexIO-simulated I2S (FlexIO\_I2S)

#### 26.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for using FlexIO to simulate I2S (flexio\_i2s) on the FlexIO block of Kinetis devices.

#### Modules

- [FlexIO I2S HAL driver](#)
- [FlexIO I2S peripheral driver](#)

## FlexIO I2S HAL driver

### 26.2 FlexIO I2S HAL driver

#### 26.2.1 Overview

This section describes the programming interface of the FlexIO I2S HAL driver.

#### Data Structures

- struct `flexio_i2s_dev_t`  
*Define type of FlexIO I2S device. [More...](#)*
- struct `flexio_i2s_master_config_t`  
*Define type of I2S master device configuration structure. [More...](#)*
- struct `flexio_i2s_slave_config_t`  
*Define type of I2S slave device configuration structure. [More...](#)*

#### Functions

- `flexio_status_t FLEXIO_I2S_HAL_Configure_Master` (`flexio_i2s_dev_t *devPtr`, `const flexio_i2s_master_config_t *configPtr`)  
*Configure the flexio working as i2s master device.*
- `flexio_status_t FLEXIO_I2S_HAL_Configure_Slave` (`flexio_i2s_dev_t *devPtr`, `const flexio_i2s_slave_config_t *configPtr`)  
*Configure the flexio working as i2s slave device.*
- `bool FLEXIO_I2S_HAL_GetTxBufferEmptyFlag` (`flexio_i2s_dev_t *devPtr`)  
*Get the flag that tx buffer is empty.*
- `void FLEXIO_I2S_HAL_ClearTxBufferEmptyFlag` (`flexio_i2s_dev_t *devPtr`)  
*Clear the tx buffer empty flag manually.*
- `void FLEXIO_I2S_HAL_SetTxBufferEmptyIntCmd` (`flexio_i2s_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for tx buffer empty.*
- `bool FLEXIO_I2S_HAL_GetTxBufferEmptyIntCmd` (`flexio_i2s_dev_t *devPtr`)  
*Get the current setting of interrupt switcher.*
- `bool FLEXIO_I2S_HAL_GetTxErrFlag` (`flexio_i2s_dev_t *devPtr`)  
*Get the rx error flag.*
- `void FLEXIO_I2S_HAL_ClearTxErrFlag` (`flexio_i2s_dev_t *devPtr`)  
*Clear the tx error flag manually.*
- `void FLEXIO_I2S_HAL_SetTxErrIntCmd` (`flexio_i2s_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for tx error.*
- `void FLEXIO_I2S_HAL_PutData` (`flexio_i2s_dev_t *devPtr`, `uint32_t dat`)  
*Put the data into tx buffer.*
- `void FLEXIO_I2S_HAL_PutDataPolling` (`flexio_i2s_dev_t *devPtr`, `uint32_t dat`)  
*Put the data into tx buffer when empty.*
- `void FLEXIO_I2S_HAL_SetTxDmaCmd` (`flexio_i2s_dev_t *devPtr`, `bool enable`)  
*Switch on/off the tx DMA support.*
- `uint32_t FLEXIO_I2S_HAL_GetTxBufferAddr` (`flexio_i2s_dev_t *devPtr`)  
*Get the address of tx buffer when using DMA.*
- `bool FLEXIO_I2S_HAL_GetRxBufferFullFlag` (`flexio_i2s_dev_t *devPtr`)  
*Get the flag if the rx buffer is full.*
- `void FLEXIO_I2S_HAL_ClearRxBufferFullFlag` (`flexio_i2s_dev_t *devPtr`)

- Clear the rx buffer full flag.*

  - void `FLEXIO_I2S_HAL_SetRxBufferFullIntCmd` (`flexio_i2s_dev_t *devPtr`, bool enable)
- Switch on/off the interrupt for rx buffer full.*

  - bool `FLEXIO_I2S_HAL_GetRxBufferFullIntCmd` (`flexio_i2s_dev_t *devPtr`)
- Get the current setting of tx buffer full interrupt.*

  - bool `FLEXIO_I2S_HAL_GetRxErrFlag` (`flexio_i2s_dev_t *devPtr`)
- Get the flag if rx error.*

  - void `FLEXIO_I2S_HAL_ClearRxErrFlag` (`flexio_i2s_dev_t *devPtr`)
- Clear the rx error flag manually.*

  - void `FLEXIO_I2S_HAL_SetRxErrIntCmd` (`flexio_i2s_dev_t *devPtr`, bool enable)
- Switch on/off the interrupt for rx error event.*

  - uint32\_t `FLEXIO_I2S_HAL_GetData` (`flexio_i2s_dev_t *devPtr`)
- Get the data from rx buffer.*

  - uint32\_t `FLEXIO_I2S_HAL_GetDataPolling` (`flexio_i2s_dev_t *devPtr`)
- Get the data from rx buffer when full.*

  - void `FLEXIO_I2S_HAL_SetRxDmaCmd` (`flexio_i2s_dev_t *devPtr`, bool enable)
- Switch on/off the rx DMA support.*

  - uint32\_t `FLEXIO_I2S_HAL_GetRxBufferAddr` (`flexio_i2s_dev_t *devPtr`)
- Get the address of rx buffer when using DMA.*

## 26.2.2 Data Structure Documentation

### 26.2.2.1 struct flexio\_i2s\_dev\_t

#### Data Fields

- FLEXIO\_Type \* `flexioBase`  
*FlexIO module base address.*
- uint32\_t `txPinIdx`  
*output for cases of both master and slave.*
- uint32\_t `rxPinIdx`  
*input for cases of both master and slave.*
- uint32\_t `sckPinIdx`  
*output for master, input for slave.*
- uint32\_t `wsPinIdx`  
*output for master, input for slave.*
- uint32\_t `shifterIdx` [2]  
*Shifter index used for I2S in FlexIO.*
- uint32\_t `timerIdx` [2]  
*Timer index used for I2S in FlexIO.*

### 26.2.3 Function Documentation

26.2.3.1 `flexio_status_t FLEXIO_I2S_HAL_Configure_Master ( flexio_i2s_dev_t * devPtr,  
const flexio_i2s_master_config_t * configPtr )`

## FlexIO I2S HAL driver

### Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>devPtr</i>    | Pointer to the device.              |
| <i>configPtr</i> | Pointer to configuration structure. |

### Returns

Execution status.

### 26.2.3.2 flexio\_status\_t FLEXIO\_I2S\_HAL\_Configure\_Slave ( flexio\_i2s\_dev\_t \* *devPtr*, const flexio\_i2s\_slave\_config\_t \* *configPtr* )

### Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>devPtr</i>    | Pointer to the device.              |
| <i>configPtr</i> | Pointer to configuration structure. |

### Returns

Execution status.

### 26.2.3.3 bool FLEXIO\_I2S\_HAL\_GetTxBufferEmptyFlag ( flexio\_i2s\_dev\_t \* *devPtr* )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Assertion of the event.

### 26.2.3.4 void FLEXIO\_I2S\_HAL\_ClearTxBufferEmptyFlag ( flexio\_i2s\_dev\_t \* *devPtr* )

### Parameters

---

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**26.2.3.5 void FLEXIO\_I2S\_HAL\_SetTxBufferEmptyIntCmd ( flexio\_i2s\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**26.2.3.6 bool FLEXIO\_I2S\_HAL\_GetTxBufferEmptyIntCmd ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

The setting of event.

**26.2.3.7 bool FLEXIO\_I2S\_HAL\_GetTxErrFlag ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**26.2.3.8 void FLEXIO\_I2S\_HAL\_ClearTxErrFlag ( flexio\_i2s\_dev\_t \* devPtr )**

## FlexIO I2S HAL driver

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 26.2.3.9 void FLEXIO\_I2S\_HAL\_SetTxErrIntCmd ( flexio\_i2s\_dev\_t \* *devPtr*, bool *enable* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 26.2.3.10 void FLEXIO\_I2S\_HAL\_PutData ( flexio\_i2s\_dev\_t \* *devPtr*, uint32\_t *dat* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 26.2.3.11 void FLEXIO\_I2S\_HAL\_PutDataPolling ( flexio\_i2s\_dev\_t \* *devPtr*, uint32\_t *dat* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 26.2.3.12 void FLEXIO\_I2S\_HAL\_SetTxDmaCmd ( flexio\_i2s\_dev\_t \* *devPtr*, bool *enable* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

|               |                        |
|---------------|------------------------|
| <i>enable</i> | Switcher to the event. |
|---------------|------------------------|

**26.2.3.13 uint32\_t FLEXIO\_I2S\_HAL\_GetTxBufferAddr ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Address of tx buffer.

**26.2.3.14 bool FLEXIO\_I2S\_HAL\_GetRxBufferFullFlag ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**26.2.3.15 void FLEXIO\_I2S\_HAL\_ClearRxBufferFullFlag ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**26.2.3.16 void FLEXIO\_I2S\_HAL\_SetRxBufferFullIntCmd ( flexio\_i2s\_dev\_t \* devPtr, bool *enable* )**

Parameters

---

## FlexIO I2S HAL driver

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 26.2.3.17 bool FLEXIO\_I2S\_HAL\_GetRxBufferFullIntCmd ( flexio\_i2s\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of event.

### 26.2.3.18 bool FLEXIO\_I2S\_HAL\_GetRxErrFlag ( flexio\_i2s\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

### 26.2.3.19 void FLEXIO\_I2S\_HAL\_ClearRxErrFlag ( flexio\_i2s\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 26.2.3.20 void FLEXIO\_I2S\_HAL\_SetRxErrIntCmd ( flexio\_i2s\_dev\_t \* devPtr, bool enable )

Parameters

---

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Swichter to the event. |

**26.2.3.21 uint32\_t FLEXIO\_I2S\_HAL\_GetData ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Reading data.

**26.2.3.22 uint32\_t FLEXIO\_I2S\_HAL\_GetDataPolling ( flexio\_i2s\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Reading data.

**26.2.3.23 void FLEXIO\_I2S\_HAL\_SetRxDmaCmd ( flexio\_i2s\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**26.2.3.24 uint32\_t FLEXIO\_I2S\_HAL\_GetRxBufferAddr ( flexio\_i2s\_dev\_t \* devPtr )**

## FlexIO I2S HAL driver

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Address of rx buffer.

## 26.3 FlexIO I2S peripheral driver

### 26.3.1 Overview

This section describes the programming interface of the FlexIO I2S Peripheral driver. The FlexIO I2S Peripheral driver provides functions for a I2S device to send and receive data.

### 26.3.2 FlexIO I2S device structures

The driver uses an instantiation of the [flexio\\_i2s\\_handler\\_t](#) structure to maintain the current state of a particular FlexIO-simulated I2S driver. This structures holds data that is used by the FlexIO-simulated I2S Peripheral driver to communicate between the transmit and receive transfer functions and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. Because the driver itself does not statically allocate memory, the caller provides memory for the driver state structure during initialization by providing a structure.

### 26.3.3 FlexIO I2S User configuration structures

The FlexIO-simulated I2S driver uses instances of the user configuration structure [flexio\\_i2s\\_config\\_t](#) for the FlexIO-simulated I2S driver. The user settings include: I2S mode(master or slave), sample rate, audio data bit count, FlexIO base pin DMA source and the associated FlexIO timers, shifters, and pin.

### 26.3.4 FlexIO I2S Initialization

1. To initialize the FlexIO I2S driver, call the [FLEXIO\\_I2S\\_DRV\\_Init\(\)](#) function and pass the instance number of the FlexIO peripheral, memory for the run-time state structure, and a pointer to the user configuration structure. For example, to use FlexIO0 pass a value of 0 to the initialization function.
2. Then, pass the memory for the run-time state structure.
3. Finally, pass a user configuration structure of the type [flexio\\_i2s\\_config\\_t](#).

The [flexio\\_i2s\\_user](#) configuration contents can be easily modified to configure the FlexIO I2S peripheral driver either to a different audio data format or using different FlexIO hardware resource. This is an example code to set up a user FlexIO I2S configuration instantiation:

```
flexio_i2s_config_t i2sConfig;
i2sConfig.data_depth = 16;
i2sConfig.sample_rate = 12000;
i2sConfig.masterslave = kFlexioI2SSlave;
i2sConfig.txPinIdx = 0; //FlexIO pin0 as transmit data line
i2sConfig.rxPinIdx = 1; //FlexIO pin1 as receive data line
i2sConfig.sckPinIdx = 4; // FlexIO pin4 as SCLK
i2sConfig.wsPinIdx = 5; //FlexIO pin5 as Frame Sync
i2sConfig.shifterIdx[0] = 0; //Use shifter 0 for transmit data
i2sConfig.shifterIdx[1] = 1; // Use shifter 1 for receive data
i2sConfig.timerIdx[0] = 0; // Use Timer0 as SCLK controller.
i2sConfig.timerIdx[1] = 1; // Use Timer1 as Frame Sync controller.
```

## FlexIO I2S peripheral driver

### 26.3.5 FlexIO I2S Data Transactions

The driver implements transmit and receive functions to transfer buffers of data in an interrupt and DAM methods. Both interrupt and DMA transfer functions are non-blocking. This code examples shows how to use the functions, assuming that the FLEXIO I2S module has been initialized as described previously in the Initialization Section.

Ensure that data is consistent when there is cache in memory and when using DMA to transfer data. In other words, when reading the data from memory, ensure that data from or to the memory device is not cached.

For blocking transfer functions transmit and receive:

```
uint8_t music[MUSIC_LEN];
FLEXIO_I2S_DRV_SendDataInt(&i2s_handler, (uint8_t *)music, MUSIC_LEN);
osa_status_t status;
//Wait for data transfer finished
do
{
 status = OSA_SemaWait(&i2s_handler.tx_sem), OSA_WAIT_FOREVER);
}while(status == kStatus_OSA_Idle);
```

### Data Structures

- struct [flexio\\_i2s\\_config\\_t](#)  
*Define the audio data format. [More...](#)*
- struct [flexio\\_i2s\\_handler\\_t](#)  
*Defines the operation handler. [More...](#)*

### Typedefs

- typedef void(\* [i2s\\_callback](#) )(void \*param)  
*Callback function of I2S.*

### Enumerations

- enum [flexio\\_i2s\\_status\\_t](#)  
*FlexIO I2S status.*
- enum [flexio\\_i2s\\_master\\_slave\\_t](#) {  
    [kFlexioI2SMaster](#) = 0U,  
    [kFlexioI2SSlave](#) = 1U }  
*Master or slave enumeration.*

### FlexIO I2S Driver

- [flexio\\_i2s\\_status\\_t FLEXIO\\_I2S\\_DRV\\_Init](#) (uint32\_t instance, [flexio\\_i2s\\_handler\\_t](#) \*handler, const [flexio\\_i2s\\_config\\_t](#) \*userConfig)

- Initializes the I2S transfer using the FlexIO.*

  - `flexio_i2s_status_t FLEXIO_I2S_DRV_Deinit` (`flexio_i2s_handler_t *handler`)

*De-initializes the FlexIO I2S.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_TxStart` (`flexio_i2s_handler_t *handler`)

*Starts the I2S transfer.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_RxStart` (`flexio_i2s_handler_t *handler`)

*Starts the I2S receive.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_TxStop` (`flexio_i2s_handler_t *handler`)

*Stops the I2S transfer.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_RxStop` (`flexio_i2s_handler_t *handler`)

*Stops the I2S receive.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_SendDataInt` (`flexio_i2s_handler_t *handler`, `uint8_t *addr`, `uint32_t len`)

*Sends data as an interrupt.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_ReceiveDataInt` (`flexio_i2s_handler_t *handler`, `uint8_t *addr`, `uint32_t len`)

*Receives data as an interrupt.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_SendDataDma` (`flexio_i2s_handler_t *handler`, `uint8_t *addr`, `uint32_t len`)

*Sends data using the DMA.*

- `flexio_i2s_status_t FLEXIO_I2S_DRV_ReceiveDataDma` (`flexio_i2s_handler_t *handler`, `uint8_t *addr`, `uint32_t len`)

*Receives data using the DMA.*

- `void FLEXIO_I2S_DRV_TxInstallCallback` (`flexio_i2s_handler_t *handler`, `i2s_callback` callback, `void *param`)

*Installs the callback function for complete data sending.*

- `void FLEXIO_I2S_DRV_RxInstallCallback` (`flexio_i2s_handler_t *handler`, `i2s_callback` callback, `void *param`)

*Installs the callback function for complete data receiving.*

## 26.3.6 Data Structure Documentation

### 26.3.6.1 struct flexio\_i2s\_config\_t

#### Data Fields

- `uint32_t txPinIdx`  
*Transmit pin.*
- `uint32_t rxPinIdx`  
*Receive pin.*
- `uint32_t sckPinIdx`  
*Clock pin.*
- `uint32_t wsPinIdx`  
*Word select pin.*
- `uint32_t shifterIdx` [2]  
*Selects two shifters.*
- `uint32_t timerIdx` [2]  
*Selects two timers.*
- `flexio_i2s_master_slave_t master_slave`

## FlexIO I2S peripheral driver

- *Acts as master or slave.*
- `uint32_t sample_rate`  
*Sample rate in Hz.*
- `uint32_t data_depth`  
*Data depth, can be 8, 16, 24, or 32 bits.*
- `dma_request_source_t baseSource`  
*DMA request source number for FlexIO pin0.*

### 26.3.6.1.0.114 Field Documentation

#### 26.3.6.1.0.114.1 `uint32_t flexio_i2s_config_t::txPinIdx`

Output for cases of both master and slave.

### 26.3.7 Enumeration Type Documentation

#### 26.3.7.1 `enum flexio_i2s_master_slave_t`

Enumerator

- kFlexioI2SMaster* As a I2S master.
- kFlexioI2SSlave* As a I2S slave.

## 26.3.8 Function Documentation

### 26.3.8.1 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_Init ( uint32\_t *instance*, flexio\_i2s\_handler\_t \* *handler*, const flexio\_i2s\_config\_t \* *userConfig* )

This interface transfers the FlexIO resource structure to a function which configures the pin/timer/shifter to act as an I2S master/slave.

## FlexIO I2S peripheral driver

### Parameters

|                   |                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>   | FlexIO I2S instance.                                                                                                                                                                           |
| <i>handler</i>    | FlexIO I2S handler; Transfer memory to the driver and this memory is used until deinitialization function is called.                                                                           |
| <i>userConfig</i> | The user configuration structure of type <a href="#">flexio_i2c_userconfig_t</a> . The user populates the members of this structure and passes the pointer of this structure to this function. |

### Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.2 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_Deinit ( flexio\_i2s\_handler\_t \* handler )

This function does not free the FlexIO resource. It only clears the internal state.

### Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

### Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.3 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_TxStart ( flexio\_i2s\_handler\_t \* handler )

### Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

### Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.4 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_RxStart ( flexio\_i2s\_handler\_t \* handler )

Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

Returns

An error code or kStatus\_FlexioI2S\_Success.

**26.3.8.5 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_TxStop ( flexio\_i2s\_handler\_t \* *handler* )**

Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

Returns

An error code or kStatus\_FlexioI2S\_Success.

**26.3.8.6 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_RxStop ( flexio\_i2s\_handler\_t \* *handler* )**

Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

Returns

An error code or kStatus\_FlexioI2S\_Success.

**26.3.8.7 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_SendDataInt ( flexio\_i2s\_handler\_t \* *handler*, uint8\_t \* *addr*, uint32\_t *len* )**

Parameters

|                |                     |
|----------------|---------------------|
| <i>handler</i> | FlexIO I2S handler. |
|----------------|---------------------|

## FlexIO I2S peripheral driver

|             |                                |
|-------------|--------------------------------|
| <i>addr</i> | Start address of data to send. |
| <i>len</i>  | Bytes to send.                 |

Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.8 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_ReceiveDataInt ( flexio\_i2s\_handler\_t \* handler, uint8\_t \* addr, uint32\_t len )

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>handler</i> | FlexIO I2S handler.               |
| <i>addr</i>    | Start address of data to receive. |
| <i>len</i>     | Bytes to receive.                 |

Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.9 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_SendDataDma ( flexio\_i2s\_handler\_t \* handler, uint8\_t \* addr, uint32\_t len )

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>handler</i> | FlexIO I2S handler.                |
| <i>addr</i>    | Start address of data to transfer. |
| <i>len</i>     | Bytes to transfer.                 |

Returns

An error code or kStatus\_FlexioI2S\_Success.

### 26.3.8.10 flexio\_i2s\_status\_t FLEXIO\_I2S\_DRV\_ReceiveDataDma ( flexio\_i2s\_handler\_t \* handler, uint8\_t \* addr, uint32\_t len )

## Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>handler</i> | FlexIO I2S handler                |
| <i>addr</i>    | Start address of data to receive. |
| <i>len</i>     | Bytes to receive.                 |

## Returns

An error code or kStatus\_FlexioI2S\_Success.

**26.3.8.11 void FLEXIO\_I2S\_DRV\_TxInstallCallback ( flexio\_i2s\_handler\_t \* *handler*,  
i2s\_callback *callback*, void \* *param* )**

The user-defined callback function is called by the transmit interrupt handler or the transfer DMA/eDMA callback function.

## Parameters

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <i>handler</i>  | FlexIO I2S handler.                                                    |
| <i>callback</i> | User-defined callback function pointer.                                |
| <i>param</i>    | User-defined callback function parameter. It should be a void pointer. |

**26.3.8.12 void FLEXIO\_I2S\_DRV\_RxInstallCallback ( flexio\_i2s\_handler\_t \* *handler*,  
i2s\_callback *callback*, void \* *param* )**

The user-defined callback function is called by the receive interrupt handler or the receive DMA/eDMA callback function.

## Parameters

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <i>handler</i>  | FlexIO I2S handler.                                                    |
| <i>callback</i> | User-defined callback function pointer.                                |
| <i>param</i>    | User-defined callback function parameter. It should be a void pointer. |

---

## Chapter 27

### FlexIO-simulated SPI (FlexIO\_SPI)

#### 27.1 Overview

The Kinetis SDK provides both HAL and peripheral drivers for using FlexIO to simulate SPI (FlexIO\_SPI) on the FlexIO block of Kinetis devices.

#### Modules

- [FlexIO SPI HAL driver](#)
- [FlexIO\\_SPI peripheral driver](#)

## FlexIO SPI HAL driver

### 27.2 FlexIO SPI HAL driver

#### 27.2.1 Overview

This section describes the programming interface of the FlexIO SPI HAL driver.

#### Data Structures

- struct `flexio_spi_dev_t`  
*Define structure of configuring the flexio spi device. [More...](#)*
- struct `flexio_spi_master_config_t`  
*Define structure of configuring the flexio spi bus when master. [More...](#)*
- struct `flexio_spi_slave_config_t`  
*Define structure of configuring the flexio spi bus when slave. [More...](#)*

#### Functions

- `flexio_status_t FLEXIO_SPI_HAL_ConfigMaster` (`flexio_spi_dev_t *devPtr`, `const flexio_spi_master_config_t *configPtr`)  
*Configure the flexio working as spi master.*
- `flexio_status_t FLEXIO_SPI_HAL_ConfigSlave` (`flexio_spi_dev_t *devPtr`, `const flexio_spi_slave_config_t *configPtr`)  
*Configure the flexio working as spi slave.*
- `bool FLEXIO_SPI_HAL_GetTxBufferEmptyFlag` (`flexio_spi_dev_t *devPtr`)  
*Get the flag if the tx buffer is empty.*
- `void FLEXIO_SPI_HAL_ClearTxBufferEmptyFlag` (`flexio_spi_dev_t *devPtr`)  
*Clear the flag that tx buffer is empty.*
- `void FLEXIO_SPI_HAL_SetTxBufferEmptyIntCmd` (`flexio_spi_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for event of tx buffer empty.*
- `bool FLEXIO_SPI_HAL_GetTxErrFlag` (`flexio_spi_dev_t *devPtr`)  
*Get the flag of tx error.*
- `void FLEXIO_SPI_HAL_ClearTxErrFlag` (`flexio_spi_dev_t *devPtr`)  
*Clear the flag of tx error manually.*
- `void FLEXIO_SPI_HAL_SetTxErrIntCmd` (`flexio_spi_dev_t *devPtr`, `bool enable`)  
*Switch on/off the interrupt for tx error event.*
- `void FLEXIO_SPI_HAL_PutDataMSB` (`flexio_spi_dev_t *devPtr`, `uint32_t dat`)  
*Put the data to tx buffer as MSB transfer.*
- `void FLEXIO_SPI_HAL_PutDataMSBPolling` (`flexio_spi_dev_t *devPtr`, `uint32_t dat`)  
*Put the data to tx buffer as MSB transfer when empty.*
- `void FLEXIO_SPI_HAL_PutDataLSB` (`flexio_spi_dev_t *devPtr`, `uint32_t dat`)  
*Put the data to tx buffer as LSB transfer.*
- `void FLEXIO_SPI_HAL_PutDataLSBPolling` (`flexio_spi_dev_t *devPtr`, `uint32_t dat`)  
*Put the data to tx buffer as LSB transfer when empty.*
- `void FLEXIO_SPI_HAL_SetTxDmaCmd` (`flexio_spi_dev_t *devPtr`, `bool enable`)  
*Switch on/off the DMA support for tx event.*
- `uint32_t FLEXIO_SPI_HAL_GetTxBufferMSBAddr` (`flexio_spi_dev_t *devPtr`)  
*Get the tx MSB buffer's register for DMA use.*
- `uint32_t FLEXIO_SPI_HAL_GetTxBufferLSBAddr` (`flexio_spi_dev_t *devPtr`)

- *Get the tx LSB buffer's register for DMA use.*
- bool **FLEXIO\_SPI\_HAL\_GetRxBufferFullFlag** (flexio\_spi\_dev\_t \*devPtr)  
*Get the flag if the rx buffer is full.*
- void **FLEXIO\_SPI\_HAL\_ClearRxBufferFullFlag** (flexio\_spi\_dev\_t \*devPtr)  
*Clear the flag of rx buffer full manually.*
- void **FLEXIO\_SPI\_HAL\_SetRxBufferFullIntCmd** (flexio\_spi\_dev\_t \*devPtr, bool enable)  
*Switch on/off the interrupt of rx buffer full event.*
- bool **FLEXIO\_SPI\_HAL\_GetRxErrFlag** (flexio\_spi\_dev\_t \*devPtr)  
*Get the flag of rx error.*
- void **FLEXIO\_SPI\_HAL\_ClearRxErrFlag** (flexio\_spi\_dev\_t \*devPtr)  
*Clear the flag of rx error manually.*
- void **FLEXIO\_SPI\_HAL\_SetRxErrIntCmd** (flexio\_spi\_dev\_t \*devPtr, bool enable)  
*Switch on/off the interrupt of the rx error event.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetDataMSB** (flexio\_spi\_dev\_t \*devPtr)  
*Get the data from rx MSB buffer.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetDataMSBPolling** (flexio\_spi\_dev\_t \*devPtr)  
*Get the data from rx MSB buffer when full.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetDataLSB** (flexio\_spi\_dev\_t \*devPtr)  
*Get the data from rx LSB buffer.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetDataLSBPolling** (flexio\_spi\_dev\_t \*devPtr)  
*Get the data from rx LSB buffer when full.*
- void **FLEXIO\_SPI\_HAL\_SetRxDmaCmd** (flexio\_spi\_dev\_t \*devPtr, bool enable)  
*Swtich on/off the DMA for rx event.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetRxBufferMSBAddr** (flexio\_spi\_dev\_t \*devPtr)  
*Get the address of rx MSB buffer.*
- uint32\_t **FLEXIO\_SPI\_HAL\_GetRxBufferLSBAddr** (flexio\_spi\_dev\_t \*devPtr)  
*Get the address of rx LSB buffer.*

## 27.2.2 Data Structure Documentation

### 27.2.2.1 struct flexio\_spi\_dev\_t

#### Data Fields

- FLEXIO\_Type \* **flexioBase**  
*FlexIO module base address.*
- uint32\_t **txPinIdx**  
*Output pin index.*
- uint32\_t **rxPinIdx**  
*Input pin index.*
- uint32\_t **sclkPinIdx**  
*Clock line, output for master, input for slave.*
- uint32\_t **csnPinIdx**  
*Chip select line, output for master, input for slave.*
- uint32\_t **shifterIdx** [2]  
*Shifter index.*
- uint32\_t **timerIdx** [2]  
*Timer index.*

## FlexIO SPI HAL driver

### 27.2.2.1.0.116 Field Documentation

27.2.2.1.0.116.1 `FLEXIO_Type* flexio_spi_dev_t::flexioBase`

27.2.2.1.0.116.2 `uint32_t flexio_spi_dev_t::txPinIdx`

27.2.2.1.0.116.3 `uint32_t flexio_spi_dev_t::rxPinIdx`

27.2.2.1.0.116.4 `uint32_t flexio_spi_dev_t::sclkPinIdx`

27.2.2.1.0.116.5 `uint32_t flexio_spi_dev_t::csnPinIdx`

27.2.2.1.0.116.6 `uint32_t flexio_spi_dev_t::shifterIdx[2]`

27.2.2.1.0.116.7 `uint32_t flexio_spi_dev_t::timerIdx[2]`

timer 0 is available for both master and slave. timer 1 would be only available for master and not used in slave mode.

### 27.2.2.2 struct flexio\_spi\_master\_config\_t

#### Data Fields

- `uint32_t flexioBusClk`  
*Clock frequency of flexio bus.*
- `uint32_t baudrate`  
*Baudrate for spi bus.*
- `uint32_t bitCount`  
*Bit count for each word.*
- `bool cphaOneEnable`  
*The phase of spi.*

### 27.2.2.2.0.117 Field Documentation

27.2.2.2.0.117.1 `uint32_t flexio_spi_master_config_t::flexioBusClk`

27.2.2.2.0.117.2 `uint32_t flexio_spi_master_config_t::baudrate`

27.2.2.2.0.117.3 `uint32_t flexio_spi_master_config_t::bitCount`

27.2.2.2.0.117.4 `bool flexio_spi_master_config_t::cphaOneEnable`

### 27.2.2.3 struct flexio\_spi\_slave\_config\_t

#### Data Fields

- `uint32_t bitCount`  
*Bit count for each word.*
- `bool cphaOneEnable`  
*The phase of spi.*

### 27.2.2.3.0.118 Field Documentation

27.2.2.3.0.118.1 `uint32_t flexio_spi_slave_config_t::bitCount`

27.2.2.3.0.118.2 `bool flexio_spi_slave_config_t::cphaOneEnable`

### 27.2.3 Function Documentation

27.2.3.1 `flexio_status_t FLEXIO_SPI_HAL_ConfigMaster ( flexio_spi_dev_t * devPtr,  
const flexio_spi_master_config_t * configPtr )`

## FlexIO SPI HAL driver

### Parameters

|                  |                                         |
|------------------|-----------------------------------------|
| <i>devPtr</i>    | Pointer to the device.                  |
| <i>configPtr</i> | Pointer to the configuration structure. |

### Returns

Execution status.

### 27.2.3.2 flexio\_status\_t FLEXIO\_SPI\_HAL\_ConfigSlave ( flexio\_spi\_dev\_t \* *devPtr*, const flexio\_spi\_slave\_config\_t \* *configPtr* )

### Parameters

|                  |                                         |
|------------------|-----------------------------------------|
| <i>devPtr</i>    | Pointer to the device.                  |
| <i>configPtr</i> | Pointer to the configuration structure. |

### Returns

Execution status.

### 27.2.3.3 bool FLEXIO\_SPI\_HAL\_GetTxBufferEmptyFlag ( flexio\_spi\_dev\_t \* *devPtr* )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Assertion of the event.

### 27.2.3.4 void FLEXIO\_SPI\_HAL\_ClearTxBufferEmptyFlag ( flexio\_spi\_dev\_t \* *devPtr* )

### Parameters

---

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**27.2.3.5 void FLEXIO\_SPI\_HAL\_SetTxBufferEmptyIntCmd ( flexio\_spi\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**27.2.3.6 bool FLEXIO\_SPI\_HAL\_GetTxErrFlag ( flexio\_spi\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**27.2.3.7 void FLEXIO\_SPI\_HAL\_ClearTxErrFlag ( flexio\_spi\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**27.2.3.8 void FLEXIO\_SPI\_HAL\_SetTxErrIntCmd ( flexio\_spi\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

## FlexIO SPI HAL driver

|               |                        |
|---------------|------------------------|
| <i>enable</i> | Switcher to the event. |
|---------------|------------------------|

### 27.2.3.9 void FLEXIO\_SPI\_HAL\_PutDataMSB ( flexio\_spi\_dev\_t \* devPtr, uint32\_t dat )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 27.2.3.10 void FLEXIO\_SPI\_HAL\_PutDataMSBPolling ( flexio\_spi\_dev\_t \* devPtr, uint32\_t dat )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 27.2.3.11 void FLEXIO\_SPI\_HAL\_PutDataLSB ( flexio\_spi\_dev\_t \* devPtr, uint32\_t dat )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 27.2.3.12 void FLEXIO\_SPI\_HAL\_PutDataLSBPolling ( flexio\_spi\_dev\_t \* devPtr, uint32\_t dat )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

**27.2.3.13** void FLEXIO\_SPI\_HAL\_SetTxDmaCmd ( flexio\_spi\_dev\_t \* *devPtr*, bool *enable* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**27.2.3.14** uint32\_t FLEXIO\_SPI\_HAL\_GetTxBufferMSBAddr ( flexio\_spi\_dev\_t \* *devPtr* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Address of tx MSB buffer.

**27.2.3.15** uint32\_t FLEXIO\_SPI\_HAL\_GetTxBufferLSBAddr ( flexio\_spi\_dev\_t \* *devPtr* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Address of tx LSB buffer.

**27.2.3.16** bool FLEXIO\_SPI\_HAL\_GetRxBufferFullFlag ( flexio\_spi\_dev\_t \* *devPtr* )

Parameters

---

## FlexIO SPI HAL driver

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of event.

### 27.2.3.17 void FLEXIO\_SPI\_HAL\_ClearRxBufferFullFlag ( flexio\_spi\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 27.2.3.18 void FLEXIO\_SPI\_HAL\_SetRxBufferFullIntCmd ( flexio\_spi\_dev\_t \* devPtr, bool enable )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 27.2.3.19 bool FLEXIO\_SPI\_HAL\_GetRxErrFlag ( flexio\_spi\_dev\_t \* devPtr )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of event.

### 27.2.3.20 void FLEXIO\_SPI\_HAL\_ClearRxErrFlag ( flexio\_spi\_dev\_t \* devPtr )

Parameters

---

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**27.2.3.21 void FLEXIO\_SPI\_HAL\_SetRxErrIntCmd ( flexio\_spi\_dev\_t \* devPtr, bool enable )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**27.2.3.22 uint32\_t FLEXIO\_SPI\_HAL\_GetDataMSB ( flexio\_spi\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from rx MSB buffer.

**27.2.3.23 uint32\_t FLEXIO\_SPI\_HAL\_GetDataMSBPolling ( flexio\_spi\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from rx MSB buffer.

**27.2.3.24 uint32\_t FLEXIO\_SPI\_HAL\_GetDataLSB ( flexio\_spi\_dev\_t \* devPtr )**

## FlexIO SPI HAL driver

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Data from rx LSB buffer.

### 27.2.3.25 uint32\_t FLEXIO\_SPI\_HAL\_GetDataLSBPolling ( flexio\_spi\_dev\_t \* devPtr )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Data from rx LSB buffer.

### 27.2.3.26 void FLEXIO\_SPI\_HAL\_SetRxDmaCmd ( flexio\_spi\_dev\_t \* devPtr, bool enable )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 27.2.3.27 uint32\_t FLEXIO\_SPI\_HAL\_GetRxBufferMSBAddr ( flexio\_spi\_dev\_t \* devPtr )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

Address of rx MSB buffer.

### 27.2.3.28 uint32\_t FLEXIO\_SPI\_HAL\_GetRxBufferLSBAddr ( flexio\_spi\_dev\_t \* devPtr )

## Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

## Returns

Address of rx MSB buffer.

## FlexIO\_SPI peripheral driver

### 27.3 FlexIO\_SPI peripheral driver

#### 27.3.1 Overview

This section describes the programming interface of the FlexIO SPI peripheral driver. The FlexIO SPI peripheral driver provides functions for device to send and receive data.

#### 27.3.2 FlexIO SPI device structures

The driver uses an instantiation of the [flexio\\_spi\\_state\\_t](#) structure to maintain the current state of a particular FlexIO-simulated SPI module driver. This structures holds data that is used by the FlexIO simulated SPI Peripheral driver to communicate between the transmit and receive transfer functions and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. Because the driver itself does not statically allocate memory, the caller provides memory for the driver state structure during initialization by providing a structure.

#### 27.3.3 FlexIO SPI user configuration structures

The FlexIO-simulated SPI driver uses instances of the user configuration structure [flexio\\_spi\\_userconfig\\_t](#) for the FlexIO-simulated SPI driver. This enables configuration of the most common settings of the SPI with a single function call. The FlexIO-simulated SPI does not support CPOL = 1. The user settings include: SPI mode(master or slave), baud rate, clock phase(first edge or second edge), data size(8-bit or 16-bit), bit direction (MSB or LSB) and the associated FlexIO timers, shifters and pins for CSn, SCK, SDI, and SDO.

#### 27.3.4 FlexIO SPI Initialization

1. To initialize the FlexIO SPI driver, call the [FLEXIO\\_SPI\\_DRV\\_Init\(\)](#) function and pass the instance number of the FlexIO peripheral, memory for the run-time state structure, and a pointer to the user configuration structure. For example, to use FlexIO0 pass a value of 0 to the initialization function.
2. Then, pass the memory for the run-time state structure.
3. Finally, pass a user configuration structure of the type [flexio\\_spi\\_userconfig\\_t](#) as shown here:

```
// FlexIO SPI configuration structure
typedef struct flexio_spi_userconfig{
 flexio_spi_master_slave_mode_t spiMode;
 uint32_t baudRate;
 flexio_spi_clock_phase_t clkPhase;
 flexio_spi_data_bitcount_mode_t dataSize;
 flexio_spi_shift_direction_t bitDirection;
 flexio_spi_hwconfig_t spiHwConfig;
}flexio_spi_userconfig_t;
```

The [flexio\\_spi\\_userconfig](#) instantiation can be easily modified to configure the FlexIO SPI peripheral driver either to a different baud rate, character transfer features or using different FlexIO hardware resource. This is an example code to set up a user FlexIO SPI configuration instantiation:

```
flexio_spi_userconfig_t spiConfig;
spiConfig.spiMode = kFlexIOSpiMaster;
spiConfig.baudRate = 200000;
spiConfig.clkPhase = kFlexIOSpiClockPhase_FirstEdge;
spiConfig.bitDirection = kFlexIOSpiMsbFirst;
spiConfig.dataSize = kFlexIOSpi8BitMode;
spiConfig.spiHwConfig.sdoPinIdx = 0;
spiConfig.spiHwConfig.sdiPinIdx = 1;
spiConfig.spiHwConfig.sclkPinIdx = 2;
spiConfig.spiHwConfig.csnPinIdx = 3;
spiConfig.spiHwConfig.shifterIdx[0] = 0;
spiConfig.spiHwConfig.shifterIdx[1] = 1;
spiConfig.spiHwConfig.timerIdx[0] = 0;
spiConfig.spiHwConfig.timerIdx[1] = 1;
```

This example shows how to call the `FLEXIO_SPI_DRV_Init()` given the user configuration structure and the FlexIO instance 0.

```
uint32_t flexioInstance = 0;
flexio_spi_state_t spiState; // user provides memory for the driver state structure

FLEXIO_SPI_DRV_Init(flexioInstance, &spiState, &spiConfig);
```

### 27.3.5 FlexIO SPI Data Transactions

The driver is separated into two implementations: interrupt-driven and DMA-driven. The driver implements transmit, receive and transfer functions to transfer buffers of data in blocking and non-blocking modes.

The non-blocking transmit and receive functions include the `FLEXIO_SPI_DRV_SendData()`, `FLEXIO_SPI_DRV_ReceiveData()`, and `FLEXIO_SPI_DRV_TransferData()` functions for interrupt driven, `FLEXIO_SPI_DRV_DmaSendData()/FLEXIO_SPI_DRV_EdmaSendData()`, `FLEXIO_SPI_DRV_DmaReceiveData()/FLEXIO_SPI_DRV_EdmaReceiveData()` and `FLEXIO_SPI_DRV_DmaTransferData()/FLEXIO_SPI_DRV_EdmaTransferData()` functions for DMA-driven.

The blocking (async) transmit and receive functions include the `FLEXIO_SPI_DRV_SendDataBlocking()`, `FLEXIO_SPI_DRV_ReceiveDataBlocking()` and `FLEXIO_SPI_DRV_TransferDataBlocking()` functions for interrupt-driven, `FLEXIO_SPI_DRV_DmaSendDataBlocking()/FLEXIO_SPI_DRV_EdmaSendDataBlocking()`, `FLEXIO_SPI_DRV_DmaReceiveDataBlocking()/FLEXIO_SPI_DRV_EdmaReceiveDataBlocking()` and `FLEXIO_SPI_DRV_DmaTransferDataBlocking()/FLEXIO_SPI_DRV_EdmaTransferDataBlocking()` functions for DMA-driven.

Ensure that data is consistent when there is cache in memory and when using DMA to transfer data. In other words, when reading the data from memory, ensure that data from or to the memory device is not cached.

This code example shows how to use the functions, assuming that the FlexIO-simulated SPI module has been initialized as described previously in the Initialization Section. For blocking transfer functions transmit and receive:

```
uint8_t sourceBuff[26] = {0}; // sourceBuff can be filled out with desired data
uint8_t readBuffer[26] = {0}; // readBuffer gets filled
```

## FlexIO\_SPI peripheral driver

```
uint32_t byteCount = sizeof(sourceBuff);
uint32_t rxRemainingSize = sizeof(readBuffer);

// for each use there, set timeout as "1"
// spiState is the run-time state. Pass in memory for this
// declared previously in the initialization chapter
FLEXIO_SPI_DRV_SendDataBlocking(spiState, sourceBuff, byteCount, 1); //
 function won't return until transmit is complete
FLEXIO_SPI_DRV_ReceiveDataBlocking(spiState, readBuffer, rxRemainingSize,
 timeoutValue); // function won't return until it receives all data
FLEXIO_SPI_DRV_TransferDataBlocking(spiState, sourceBuff, readBuffer,
 rxRemainingSize, timeoutValue); // function won't return until it sends and receives all data
```

For non-blocking (async) transfer functions transmit and receive:

```
uint8_t *pTxBuff;
uint8_t rxBuff[10];
uint32_t txBytesRemaining, rxBytesRemaining;

// Assume pTxBuff and txSize have been initialized
FLEXIO_SPI_DRV_SendData(spiState, pTxBuff, txSize);

// Check on status of transmit and wait until done; the code can do something else and
// check back later
while (FLEXIO_SPI_DRV_GetTransmitStatus(spiState, &txBytesRemaining) ==
 kStatus_FlexIO_SPI_TxBusy);

// For receive, assume rxBuff is set up to receive data and rxSize is initialized
FLEXIO_SPI_DRV_ReceiveData(spiState, rxBuff, rxSize);

// Check on status of receive and wait until done; The code can do something else and
// check back later
while (FLEXIO_SPI_DRV_GetReceiveStatus(spiState, &rxBytesRemaining) ==
 kStatus_FlexIO_SPI_RxBusy);

// For transfer, assume pTxBuff, rxBuff are set up to send and receive data and rxSize is initialized
FLEXIO_SPI_DRV_TransferData(spiState, pTxBuff, rxBuff, rxSize);

// Check on status of receive and wait until done; the code can do something else and
// check back later
while (FLEXIO_SPI_DRV_GetReceiveStatus(spiState, &rxBytesRemaining) ==
 kStatus_FlexIO_SPI_RxBusy);
```

## Data Structures

- struct [flexio\\_spi\\_state\\_t](#)

## FlexIO\_SPI peripheral driver

- Returns whether the previous FlexIO-simulated SPI receive is complete.*

  - `flexio_spi_status_t FLEXIO_SPI_DRV_AbortReceivingData` (`flexio_spi_state_t *spiState`)

*Terminates a non-blocking FlexIO-simulated SPI receive early.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_TransferDataBlocking` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`, `uint32_t timeout`)

*Transfers data through the FlexIO-simulated SPI module using a blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_TransferData` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`)

*Transfers data through the FlexIO-simulated SPI module using a non-blocking method.*
- `void FLEXIO_SPI_DRV_TX_IRQHandler` (`void *param`)

*Interrupt handler for the FlexIO-simulated SPI transmit.*
- `void FLEXIO_SPI_DRV_RX_IRQHandler` (`void *param`)

*Interrupt handler for the FlexIO-simulated SPI receive.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaSendDataBlocking` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint32_t txSize`, `uint32_t timeout`)

*Sends (transmits) data out through the FlexIO-simulated SPI module using an eDMA blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaSendData` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint32_t txSize`)

*Sends (transmits) data through the FlexIO-simulated SPI module using a eDMA non-blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaGetTransmitStatus` (`flexio_spi_state_t *spiState`, `uint32_t *bytesRemaining`)

*Returns whether the previous FlexIO-simulated SPI eDMA transmit is complete.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaAbortSendingData` (`flexio_spi_state_t *spiState`)

*Terminates a non-blocking FlexIO-simulated SPI eDMA transmission early.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaReceiveDataBlocking` (`flexio_spi_state_t *spiState`, `uint8_t *rxBuff`, `uint32_t rxSize`, `uint32_t timeout`)

*Gets (receives) data from the FlexIO-simulated SPI module using an eDMA blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaReceiveData` (`flexio_spi_state_t *spiState`, `uint8_t *rxBuff`, `uint32_t rxSize`)

*Gets (receives) data from the FlexIO-simulated SPI module using an eDMA non-blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaGetReceiveStatus` (`flexio_spi_state_t *spiState`, `uint32_t *bytesRemaining`)

*Returns whether the previous FlexIO-simulated SPI eDMA receive is complete.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaAbortReceivingData` (`flexio_spi_state_t *spiState`)

*Terminates a non-blocking FlexIO-simulated SPI eDMA receive early.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaTransferDataBlocking` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`, `uint32_t timeout`)

*Transfers data through the FlexIO-simulated SPI module using an eDMA blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaTransferData` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`)

*Transfers data through the FlexIO-simulated SPI module using an eDMA non-blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_DmaSendDataBlocking` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint32_t txSize`, `uint32_t timeout`)

*Sends (transmits) data out through the FlexIO-simulated SPI module using a DMA blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_DmaSendData` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint32_t txSize`)

*Sends (transmits) data through the FlexIO-simulated SPI module using a DMA non-blocking method.*
- `flexio_spi_status_t FLEXIO_SPI_DRV_DmaGetTransmitStatus` (`flexio_spi_state_t *spiState`, `uint32_t *bytesRemaining`)

- Returns whether the previous FlexIO-simulated SPI DMA transmit has finished.*

  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaAbortSendingData` (`flexio_spi_state_t *spiState`)  
*Terminates a non-blocking FlexIO-simulated SPI DMA transmission early.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaReceiveDataBlocking` (`flexio_spi_state_t *spiState`, `uint8_t *rxBuff`, `uint32_t rxSize`, `uint32_t timeout`)  
*Gets (receives) data from the FlexIO-simulated SPI module using a DMA blocking method.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaReceiveData` (`flexio_spi_state_t *spiState`, `uint8_t *rxBuff`, `uint32_t rxSize`)  
*Gets (receives) data from the FlexIO-simulated SPI module using a DMA non-blocking method.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaGetReceiveStatus` (`flexio_spi_state_t *spiState`, `uint32_t *bytesRemaining`)  
*Returns whether the previous FlexIO-simulated SPI DMA receive is complete.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_AbortDmaReceivingData` (`flexio_spi_state_t *spiState`)  
*Terminates a non-blocking FlexIO-simulated SPI DMA receive early.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaTransferDataBlocking` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`, `uint32_t timeout`)  
*Transfers data through the FlexIO-simulated SPI module using a DMA blocking method.*
  - `flexio_spi_status_t FLEXIO_SPI_DRV_DmaTransferData` (`flexio_spi_state_t *spiState`, `const uint8_t *txBuff`, `uint8_t *rxBuff`, `uint32_t xSize`)  
*Transfers data through the FlexIO-simulated SPI module using a DMA non-blocking method.*

### 27.3.6.2 struct flexio\_spi\_hwconfig\_t

These constants define the hardware resource used by the FlexIO SPI master/slave device and includes the external pin and the internal shifter and timer.

#### Data Fields

- uint32\_t [sdoPinIdx](#)  
*Output pin index.*
- uint32\_t [sdiPinIdx](#)  
*Input pin index.*

- [uint32\\_t sclkPinIdx](#)  
*Clock pin index.*
- [uint32\\_t csnPInIdx](#)  
*Chip select pin index.*
- [uint32\\_t shifterIdx](#) [2]  
*Select two shifters.*
- [uint32\\_t timerIdx](#) [2]  
*timer 0 is available for both master and slave.*

### 27.3.6.2.0.120 Field Documentation

#### 27.3.6.2.0.120.1 [uint32\\_t flexio\\_spi\\_hwconfig\\_t::sclPinIdx](#)

Output for master, input for slave.

#### 27.3.6.2.0.120.2 [uint32\\_t flexio\\_spi\\_hwconfig\\_t::csnPInIdx](#)

Output for master, input for slave.

#### 27.3.6.2.0.120.3 [uint32\\_t flexio\\_spi\\_hwconfig\\_t::timerIdx\[2\]](#)

timer 1 would be only available for master and not used in slave mode.

### 27.3.6.3 [struct flexio\\_spi\\_userconfig\\_t](#)

Use an instance of this structure with the [FLEXIO\\_SPI\\_DRV\\_Init\(\)](#)function. This enables configuration of the settings of the FlexIO SPI peripheral with a single function call. Settings include: SPI baud rate, data size, FlexIO SPI mode and FlexIO hardware resource resource.

#### Data Fields

- [flexio\\_spi\\_master\\_slave\\_mode\\_t spiMode](#)  
*Selects Master or Slave mode.*
- [uint32\\_t baudRate](#)  
*Baudrate configuration.*
- [flexio\\_spi\\_clock\\_phase\\_t clkPhase](#)  
*Clock phase configuration.*
- [flexio\\_spi\\_data\\_bitcount\\_mode\\_t dataSize](#)  
*SPI data length mode.*
- [flexio\\_spi\\_shift\\_direction\\_t bitDirection](#)  
*SPI data shifter direction options.*
- [flexio\\_spi\\_hwconfig\\_t spiHwConfig](#)  
*FlexIO SPI Resource configuration.*

## FlexIO\_SPI peripheral driver

### 27.3.7 Enumeration Type Documentation

#### 27.3.7.1 enum flexio\_spi\_status\_t

#### 27.3.7.2 enum flexio\_spi\_master\_slave\_mode\_t

Enumerator

*kFlexIOSpiMaster* SPI peripheral operates in master mode.

*kFlexIOSpiSlave* SPI peripheral operates in slave mode.

#### 27.3.7.3 enum flexio\_spi\_shift\_direction\_t

Enumerator

*kFlexIOSpiMsbFirst* Data transfers start with most significant bit.

*kFlexIOSpiLsbFirst* Data transfers start with least significant bit.

#### 27.3.7.4 enum flexio\_spi\_clock\_phase\_t

Enumerator

*kFlexIOSpiClockPhase\_FirstEdge* First edge on SPSCCK occurs at the middle of the first cycle of a data transfer.

*kFlexIOSpiClockPhase\_SecondEdge* First edge on SPSCCK occurs at the start of the first cycle of a data transfer.

#### 27.3.7.5 enum flexio\_spi\_data\_bitcount\_mode\_t

Enumerator

*kFlexIOSpi8BitMode* 8-bit data transmission mode

*kFlexIOSpi16BitMode* 16-bit data transmission mode

### 27.3.8 Function Documentation

#### 27.3.8.1 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_Init ( uint32\_t instance, flexio\_spi\_state\_t \* spiState, const flexio\_spi\_userconfig\_t \* spiConfig )

This function initializes the run-time state structure to keep track of the ongoing transfers and the module to user-defined settings and default settings. It also configures the underlying FlexIO pin, shifter, and timer. This is an example to set up the [flexio\\_spi\\_state\\_t](#) and the [flexio\\_spi\\_userconfig\\_t](#) parameters and to call the FLEXIO\_SPI\_DRV\_Init function

```
flexio_spi_userconif_t spiConfig;
spiConfig.spiMode = kFlexIOSpiMaster;
spiConfig.baudRate = 100000;
spiConfig.clkPhase = kFlexIOSpiClockPhase_FirstEdge;
spiConfig.dataSize = kFlexIOSpi8BitMode;
spiConfig.spiHwConfig.sdoPinIdx = 0;
spiConfig.spiHwConfig.sdiPinIdx = 1;
spiConfig.spiHwConfig.sclkPinIdx = 2;
spiConfig.spiHwConfig.csnPinIdx = 3;
spiConfig.spiHwConfig.shifterIdx = {0,1};
spiConfig.spiHwConfig.timerIdx = {0,1};
```

### Parameters

|                  |                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>  | The FlexIO instance number.                                                                                                                                                                                                                                   |
| <i>spiState</i>  | A pointer to the global FlexIO SPI driver state structure memory. The user passes in the memory for the run-time state structure. The FlexIO SPI driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>spiConfig</i> | The user configuration structure of type <a href="#">flexio_spi_userconfig_t</a> . The user populates the members of this structure and passes the pointer of this structure to this function.                                                                |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.2 void FLEXIO\_SPI\_DRV\_Deinit ( flexio\_spi\_state\_t \* spiState )

This function disables the FlexIO-simulated SPI trigger.

#### Parameters

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| <i>spiState</i> | The run-time structure of the FlexIO-simulated SPI. |
|-----------------|-----------------------------------------------------|

### 27.3.8.3 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_SendDataBlocking ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint32\_t txSize, uint32\_t timeout )

#### Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

## FlexIO\_SPI peripheral driver

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <i>txBuff</i>  | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>txSize</i>  | The number of bytes to send.                                             |
| <i>timeout</i> | A timeout value for RTOS abstraction sync control in milliseconds (ms).  |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.4 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_SendData ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint32\_t txSize )

#### Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                     |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.5 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_GetTransmitStatus ( flexio\_spi\_state\_t \* spiState, uint32\_t \* bytesRemaining )

#### Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of the FlexIO-simulated SPI.                                                        |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

Return values

|                                   |                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_SPI_Tx-Busy</i> | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

**27.3.8.6 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_AbortSendingData ( flexio\_spi\_state\_t \* spiState )**

Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

Returns

An error code or *kStatus\_FlexIO\_SPI\_Success*.

Return values

|                                                 |                                           |
|-------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i>               | The transmit was successful.              |
| <i>kStatus_FlexIO_SPI_No-TransmitInProgress</i> | No transmission is currently in progress. |

**27.3.8.7 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_ReceiveDataBlocking ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )**

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received. |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

## FlexIO\_SPI peripheral driver

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.8 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_ReceiveData ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize )

#### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of the FlexIO-simulated SPI.                     |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received. |
| <i>rxSize</i>   | The number of bytes to receive.                                         |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.9 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_GetReceiveStatus ( flexio\_spi\_state\_t \* spiState, uint32\_t \* bytesRemaining )

#### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of FlexIO-simulated SPI.                                                                         |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

#### Return values

|                                   |                                         |
|-----------------------------------|-----------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i> | The receive has completed successfully. |
|-----------------------------------|-----------------------------------------|

|                                   |                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI_Rx-Busy</i> | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|

### 27.3.8.10 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_AbortReceivingData ( flexio\_spi\_state\_t \* spiState )

Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

Returns

An error code or `kStatus_SPI_Success`.

Return values

|                                                |                                      |
|------------------------------------------------|--------------------------------------|
| <i>kStatus_FlexIO_SPI-Success</i>              | The receive was successful.          |
| <i>kStatus_FlexIO_SPI-NoTransmitInProgress</i> | No receive is currently in progress. |

### 27.3.8.11 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_TransferDataBlocking ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize, uint32\_t timeout )

Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received.  |
| <i>xSize</i>    | The number of bytes to send and receive.                                 |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms).  |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.12 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_TransferData ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize )

## FlexIO\_SPI peripheral driver

### Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received.  |
| <i>xSize</i>    | The number of bytes to send.                                             |

### Returns

An error code or kStatus\_FlexIO\_SPI\_Success.

### 27.3.8.13 void FLEXIO\_SPI\_DRV\_TX\_IRQHandler ( void \* *param* )

#### Parameters

|              |                                                 |
|--------------|-------------------------------------------------|
| <i>param</i> | The run-time structure of FlexIO-simulated SPI. |
|--------------|-------------------------------------------------|

### 27.3.8.14 void FLEXIO\_SPI\_DRV\_RX\_IRQHandler ( void \* *param* )

#### Parameters

|              |                                                     |
|--------------|-----------------------------------------------------|
| <i>param</i> | The run-time structure of the FlexIO-simulated SPI. |
|--------------|-----------------------------------------------------|

### 27.3.8.15 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaSendDataBlocking ( flexio\_spi\_state\_t \* *spiState*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout* )

#### Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                     |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| <i>timeout</i> | A timeout value for RTOS abstraction sync control in milliseconds (ms). |
|----------------|-------------------------------------------------------------------------|

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.16 `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaSendData ( flexio_spi_state_t * spiState, const uint8_t * txBuff, uint32_t txSize )`

Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of the FlexIO-simulated SPI.                 |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.17 `flexio_spi_status_t FLEXIO_SPI_DRV_EdmaGetTransmitStatus ( flexio_spi_state_t * spiState, uint32_t * bytesRemaining )`

Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of the FlexIO-simulated SPI.                                                        |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

Return values

---

## FlexIO\_SPI peripheral driver

|                                   |                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_SPI_Tx-Busy</i> | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 27.3.8.18 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaAbortSendingData ( flexio\_spi\_state\_t \* spiState )

#### Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

#### Returns

An error code or *kStatus\_FlexIO\_SPI\_Success*.

#### Return values

|                                                 |                                           |
|-------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i>               | The transmit was successful.              |
| <i>kStatus_FlexIO_SPI_No-TransmitInProgress</i> | No transmission is currently in progress. |

### 27.3.8.19 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaReceiveDataBlocking ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )

#### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

**27.3.8.20 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaReceiveData ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize )**

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received. |
| <i>rxSize</i>   | The number of bytes to receive.                                         |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

**27.3.8.21 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaGetReceiveStatus ( flexio\_spi\_state\_t \* spiState, uint32\_t \* bytesRemaining )**

Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of FlexIO-simulated SPI.                                                                         |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

Return values

|                                   |                                         |
|-----------------------------------|-----------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i> | The receive has completed successfully. |
|-----------------------------------|-----------------------------------------|

## FlexIO\_SPI peripheral driver

|                                   |                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI_Rx-Busy</i> | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|

### 27.3.8.22 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaAbortReceivingData ( flexio\_spi\_state\_t \* spiState )

#### Parameters

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| <i>spiState</i> | The run-time structure of the FlexIO-simulated SPI. |
|-----------------|-----------------------------------------------------|

#### Returns

An error code or *kStatus\_SPI\_Success*.

#### Return values

|                                                |                                      |
|------------------------------------------------|--------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i>              | The receive was successful.          |
| <i>kStatus_FlexIO_SPI_NoTransmitInProgress</i> | No receive is currently in progress. |

### 27.3.8.23 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaTransferDataBlocking ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize, uint32\_t timeout )

#### Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received.  |
| <i>xSize</i>    | The number of bytes to send&receive.                                     |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms).  |

#### Returns

An error code or *kStatus\_FlexIO\_SPI\_Success*.

### 27.3.8.24 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_EdmaTransferData ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize )

Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.       |
| <i>xSize</i>    | The number of bytes to send.                                             |

Returns

An error code or kStatus\_FlexIO\_SPI\_Success.

**27.3.8.25 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaSendDataBlocking ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint32\_t txSize, uint32\_t timeout )**

Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>txSize</i>   | The number of bytes to send.                                             |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms).  |

Returns

An error code or kStatus\_FlexIO\_SPI\_Success.

**27.3.8.26 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaSendData ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint32\_t txSize )**

Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                     |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |

## FlexIO\_SPI peripheral driver

|               |                              |
|---------------|------------------------------|
| <i>txSize</i> | The number of bytes to send. |
|---------------|------------------------------|

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### 27.3.8.27 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaGetTransmitStatus ( flexio\_spi\_state\_t \* spiState, uint32\_t \* bytesRemaining )

Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of FlexIO-simulated SPI.                                                            |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

Return values

|                                   |                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI-Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_SPI-Tx-Busy</i> | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 27.3.8.28 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaAbortSendingData ( flexio\_spi\_state\_t \* spiState )

Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

Returns

An error code or `kStatus_FlexIO_SPI_Success`.

## Return values

|                                                |                                           |
|------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_SPI_Success</i>              | The transmit was successful.              |
| <i>kStatus_FlexIO_SPI_NoTransmitInProgress</i> | No transmission is currently in progress. |

**27.3.8.29 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaReceiveDataBlocking ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )**

## Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received. |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

## Returns

An error code or *kStatus\_FlexIO\_SPI\_Success*.

**27.3.8.30 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaReceiveData ( flexio\_spi\_state\_t \* spiState, uint8\_t \* rxBuff, uint32\_t rxSize )**

## Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received. |
| <i>rxSize</i>   | The number of bytes to receive.                                         |

## Returns

An error code or *kStatus\_FlexIO\_SPI\_Success*.

**27.3.8.31 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaGetReceiveStatus ( flexio\_spi\_state\_t \* spiState, uint32\_t \* bytesRemaining )**

## FlexIO\_SPI peripheral driver

### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>spiState</i>        | The run-time structure of FlexIO-simulated SPI.                                                                         |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_SPI_Success`.

### Return values

|                                   |                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_SPI-Success</i> | The receive has completed successfully.                                                                                        |
| <i>kStatus_FlexIO_SPI-Rx-Busy</i> | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

### 27.3.8.32 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_AbortDmaReceivingData ( flexio\_spi\_state\_t \* spiState )

#### Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI. |
|-----------------|-------------------------------------------------|

#### Returns

An error code or `kStatus_SPI_Success`.

#### Return values

|                                                 |                                      |
|-------------------------------------------------|--------------------------------------|
| <i>kStatus_FlexIO_SPI-Success</i>               | The receive was successful.          |
| <i>kStatus_FlexIO_SPI-No-TransmitInProgress</i> | No receive is currently in progress. |

### 27.3.8.33 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaTransferDataBlocking ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize, uint32\_t timeout )

### Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received.  |
| <i>xSize</i>    | The number of bytes to send&receive.                                     |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms).  |

### Returns

An error code or kStatus\_FlexIO\_SPI\_Success.

### 27.3.8.34 flexio\_spi\_status\_t FLEXIO\_SPI\_DRV\_DmaTransferData ( flexio\_spi\_state\_t \* spiState, const uint8\_t \* txBuff, uint8\_t \* rxBuff, uint32\_t xSize )

### Parameters

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <i>spiState</i> | The run-time structure of FlexIO-simulated SPI.                          |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data characters to send. |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data characters received.  |
| <i>xSize</i>    | The number of bytes to send.                                             |

### Returns

An error code or kStatus\_FlexIO\_SPI\_Success.

## Chapter 28

# FlexIO-simulated UART (FlexIO\_UART)

### 28.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for using FlexIO to simulate UART (FlexIO\_UART) on the FlexIO block of Kinetis devices.

#### Modules

- [FlexIO UART HAL driver](#)
- [FlexIO UART peripheral driver](#)

## FlexIO UART HAL driver

### 28.2 FlexIO UART HAL driver

#### 28.2.1 Overview

This section describes the programming interface of the FlexIO UART HAL driver.

#### Data Structures

- struct `flexio_uart_tx_dev_t`  
*Define structure of configuring the FlexIO UART transmit device. [More...](#)*
- struct `flexio_uart_rx_dev_t`  
*Define structure of configuring the FlexIO UART receive device. [More...](#)*
- struct `flexio_uart_config_t`  
*Define structure of configuring the FlexIO UART bus. [More...](#)*

#### Functions

- `flexio_status_t FLEXIO_UART_Tx_HAL_Configure` (`flexio_uart_tx_dev_t *devPtr`, `const flexio_uart_config_t *configPtr`)  
*Configures the FlexIO as a UART transmit device. [More...](#)*
- `bool FLEXIO_UART_Tx_HAL_GetTxBufferEmptyFlag` (`flexio_uart_tx_dev_t *devPtr`)  
*Gets the flag which indicates whether the transmit buffer is empty.*
- `void FLEXIO_UART_Tx_HAL_ClearTxBufferEmptyFlag` (`flexio_uart_tx_dev_t *devPtr`)  
*Clears the transmit buffer empty flag manually.*
- `void FLEXIO_UART_Tx_HAL_SetTxBufferEmptyIntCmd` (`flexio_uart_tx_dev_t *devPtr`, `bool enable`)  
*Switches on/off the interrupt for the buffer empty event.*
- `bool FLEXIO_UART_Tx_HAL_GetTxBufferEmptyIntCmd` (`flexio_uart_tx_dev_t *devPtr`)  
*Gets the current setting for the transmit buffer empty event.*
- `bool FLEXIO_UART_Tx_HAL_GetTxErrFlag` (`flexio_uart_tx_dev_t *devPtr`)  
*Gets the transmit error flag.*
- `void FLEXIO_UART_Tx_HAL_ClearTxErrFlag` (`flexio_uart_tx_dev_t *devPtr`)  
*Clears the transmit error flag manually.*
- `void FLEXIO_UART_Tx_HAL_SetTxErrIntCmd` (`flexio_uart_tx_dev_t *devPtr`, `bool enable`)  
*Switches on/off the interrupt for the transmit error event.*
- `void FLEXIO_UART_Tx_HAL_PutData` (`flexio_uart_tx_dev_t *devPtr`, `uint32_t dat`)  
*Puts the data into the transmit buffer.*
- `void FLEXIO_UART_Tx_HAL_PutDataPolling` (`flexio_uart_tx_dev_t *devPtr`, `uint32_t dat`)  
*Puts the data into the transmit buffer when empty.*
- `void FLEXIO_UART_Tx_HAL_SendDataPolling` (`flexio_uart_tx_dev_t *devPtr`, `uint32_t *txBufPtr`, `uint32_t txLen`)  
*Sends an array of data by FlexIO UART transmit device.*
- `void FLEXIO_UART_Tx_HAL_SetTxDmaCmd` (`flexio_uart_tx_dev_t *devPtr`, `bool enable`)  
*Switches on/off the DMA on the FlexIO UART transmit device.*
- `uint32_t FLEXIO_UART_Tx_HAL_GetTxBufferAddr` (`flexio_uart_tx_dev_t *devPtr`)  
*Gets the transmit buffer's address for the DMA use.*
- `flexio_status_t FLEXIO_UART_Rx_HAL_Configure` (`flexio_uart_rx_dev_t *devPtr`, `const flexio_uart_config_t *configPtr`)

- Configures the FlexIO as a UART receive device.*

  - bool **FLEXIO\_UART\_Rx\_HAL\_GetRxBufferFullFlag** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the flag which indicates whether the receive buffer is full.*
  - void **FLEXIO\_UART\_Rx\_HAL\_ClearRxBufferFullFlag** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Clears the flag manually that indicates that the receive buffer is full.*
  - void **FLEXIO\_UART\_Rx\_HAL\_SetRxBufferFullIntCmd** (flexio\_uart\_rx\_dev\_t \*devPtr, bool enable)  
*Switches on/off the interrupt for the receive buffer full event.*
  - bool **FLEXIO\_UART\_Rx\_HAL\_GetRxBufferFullIntCmd** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the current setting that indicates whether the interrupt is enabled.*
  - bool **FLEXIO\_UART\_Rx\_HAL\_GetRxErrFlag** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the flag of the receive error event.*
  - void **FLEXIO\_UART\_Rx\_HAL\_ClearRxErrFlag** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Clears the flag of the receive error event manually.*
  - void **FLEXIO\_UART\_Rx\_HAL\_SetRxErrIntCmd** (flexio\_uart\_rx\_dev\_t \*devPtr, bool enable)  
*Switches on/off the interrupt for the receive error event.*
  - uint32\_t **FLEXIO\_UART\_Rx\_HAL\_GetData** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the data from the receive buffer.*
  - uint32\_t **FLEXIO\_UART\_Rx\_HAL\_GetDataPolling** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the data from the receive buffer when full.*
  - void **FLEXIO\_UART\_Rx\_HAL\_ReceiveDataPolling** (flexio\_uart\_rx\_dev\_t \*devPtr, uint32\_t \*rxBufPtr, uint32\_t rxLen)  
*Receives an array of data through the receive buffer.*
  - void **FLEXIO\_UART\_Rx\_HAL\_SetRxDmaCmd** (flexio\_uart\_rx\_dev\_t \*devPtr, bool enable)  
*Switches on/off the receive DMA support.*
  - uint32\_t **FLEXIO\_UART\_Rx\_HAL\_GetRxBufferAddr** (flexio\_uart\_rx\_dev\_t \*devPtr)  
*Gets the receive buffer's address for DMA use.*

28.2.3.1 flexio\_status\_t FLEXIO\_UART\_Tx\_HAL\_Configure ( flexio\_uart\_tx\_dev\_t \* devPtr, const flexio\_uart\_config\_t \* configPtr )

## FlexIO UART HAL driver

### Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>devPtr</i>    | Pointer to the device.              |
| <i>configPtr</i> | Pointer to configuration structure. |

### Returns

Execution status.

### 28.2.3.2 **bool FLEXIO\_UART\_Tx\_HAL\_GetTxBufferEmptyFlag ( flexio\_uart\_tx\_dev\_t \* devPtr )**

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

The assertion of the event.

### 28.2.3.3 **void FLEXIO\_UART\_Tx\_HAL\_ClearTxBufferEmptyFlag ( flexio\_uart\_tx\_dev\_t \* devPtr )**

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### 28.2.3.4 **void FLEXIO\_UART\_Tx\_HAL\_SetTxBufferEmptyIntCmd ( flexio\_uart\_tx\_dev\_t \* devPtr, bool enable )**

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**28.2.3.5 bool FLEXIO\_UART\_Tx\_HAL\_GetTxBufferEmptyIntCmd ( flexio\_uart\_tx\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Setting for the interrupt event.

**28.2.3.6 bool FLEXIO\_UART\_Tx\_HAL\_GetTxErrFlag ( flexio\_uart\_tx\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**28.2.3.7 void FLEXIO\_UART\_Tx\_HAL\_ClearTxErrFlag ( flexio\_uart\_tx\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**28.2.3.8 void FLEXIO\_UART\_Tx\_HAL\_SetTxErrIntCmd ( flexio\_uart\_tx\_dev\_t \* devPtr, bool enable )**

Parameters

## FlexIO UART HAL driver

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 28.2.3.9 void FLEXIO\_UART\_Tx\_HAL\_PutData ( flexio\_uart\_tx\_dev\_t \* *devPtr*, uint32\_t *dat* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 28.2.3.10 void FLEXIO\_UART\_Tx\_HAL\_PutDataPolling ( flexio\_uart\_tx\_dev\_t \* *devPtr*, uint32\_t *dat* )

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>dat</i>    | Sending data.          |

### 28.2.3.11 void FLEXIO\_UART\_Tx\_HAL\_SendDataPolling ( flexio\_uart\_tx\_dev\_t \* *devPtr*, uint32\_t \* *txBufPtr*, uint32\_t *txLen* )

Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>devPtr</i>   | Pointer to the device.         |
| <i>txBufPtr</i> | Pointer to the sending buffer. |
| <i>txLen</i>    | Length of sending buffer.      |

### 28.2.3.12 void FLEXIO\_UART\_Tx\_HAL\_SetTxDmaCmd ( flexio\_uart\_tx\_dev\_t \* *devPtr*, bool *enable* )

Parameters

---

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**28.2.3.13 uint32\_t FLEXIO\_UART\_Tx\_HAL\_GetTxBufferAddr ( flexio\_uart\_tx\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

tx buffer's address.

**28.2.3.14 flexio\_status\_t FLEXIO\_UART\_Rx\_HAL\_Configure ( flexio\_uart\_rx\_dev\_t \* devPtr, const flexio\_uart\_config\_t \* configPtr )**

Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>devPtr</i>    | Pointer to the device.              |
| <i>configPtr</i> | Pointer to configuration structure. |

Returns

Execution status.

**28.2.3.15 bool FLEXIO\_UART\_Rx\_HAL\_GetRxBufferFullFlag ( flexio\_uart\_rx\_dev\_t \* devPtr )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

The assertion of the event.

**28.2.3.16 void FLEXIO\_UART\_Rx\_HAL\_ClearRxBufferFullFlag ( flexio\_uart\_rx\_dev\_t \* devPtr )**

## FlexIO UART HAL driver

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**28.2.3.17 void FLEXIO\_UART\_Rx\_HAL\_SetRxBufferFullIntCmd ( flexio\_uart\_rx\_dev\_t \* *devPtr*, bool *enable* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**28.2.3.18 bool FLEXIO\_UART\_Rx\_HAL\_GetRxBufferFullIntCmd ( flexio\_uart\_rx\_dev\_t \* *devPtr* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**28.2.3.19 bool FLEXIO\_UART\_Rx\_HAL\_GetRxErrFlag ( flexio\_uart\_rx\_dev\_t \* *devPtr* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Assertion of the event.

**28.2.3.20 void FLEXIO\_UART\_Rx\_HAL\_ClearRxErrFlag ( flexio\_uart\_rx\_dev\_t \* *devPtr* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

**28.2.3.21 void FLEXIO\_UART\_Rx\_HAL\_SetRxErrIntCmd ( flexio\_uart\_rx\_dev\_t \* *devPtr*, bool *enable* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

**28.2.3.22 uint32\_t FLEXIO\_UART\_Rx\_HAL\_GetData ( flexio\_uart\_rx\_dev\_t \* *devPtr* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from the receive buffer.

**28.2.3.23 uint32\_t FLEXIO\_UART\_Rx\_HAL\_GetDataPolling ( flexio\_uart\_rx\_dev\_t \* *devPtr* )**

Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

Returns

Data from the receive buffer.

**28.2.3.24 void FLEXIO\_UART\_Rx\_HAL\_ReceiveDataPolling ( flexio\_uart\_rx\_dev\_t \* *devPtr*, uint32\_t \* *rxBufPtr*, uint32\_t *rxLen* )**

## FlexIO UART HAL driver

### Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>devPtr</i>   | Pointer to the device.         |
| <i>rxBufPtr</i> | Pointer to the receive buffer. |
| <i>rxLen</i>    | Length of the receive buffer.  |

### 28.2.3.25 void FLEXIO\_UART\_Rx\_HAL\_SetRxDmaCmd ( flexio\_uart\_rx\_dev\_t \* *devPtr*, bool *enable* )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
| <i>enable</i> | Switcher to the event. |

### 28.2.3.26 uint32\_t FLEXIO\_UART\_Rx\_HAL\_GetRxBufferAddr ( flexio\_uart\_rx\_dev\_t \* *devPtr* )

### Parameters

|               |                        |
|---------------|------------------------|
| <i>devPtr</i> | Pointer to the device. |
|---------------|------------------------|

### Returns

rx buffer's address.

## 28.3 FlexIO UART peripheral driver

### 28.3.1 Overview

This section describes the programming interface of the FlexIO UART Peripheral driver. The FlexIO UART driver transfers data to and from external devices on the Universal Asynchronous Receiver/Transmitter (UART) serial bus with a single function call.

### 28.3.2 FlexIO UART device structures

The driver uses an instantiation of the `flexio_uart_state_t` structure to maintain the current state of a particular FlexIO-simulated UART module driver. This structure holds data that is used by the FlexIO-simulated UART peripheral driver to communicate between the transmit and receive transfer functions and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. Because the driver itself does not statically allocate memory, the caller provides memory for the driver state structure during initialization by providing a structure.

### 28.3.3 FlexIO UART user configuration structures

The FlexIO-simulated UART driver uses instances of the user configuration structure `flexio_uart_userconfig_t` for the FlexIO-simulated UART driver. This enables configuration of the most common settings of the UART with a single function call. The FlexIO-simulated UART does not support the parity check and only supports one stop bit. The user settings include: UART baud rate, the number of bits per data word, UART work mode (transmit, receive, or both) and the associated FlexIO timers, shifters, and pins for transmit and receive.

### 28.3.4 FlexIO UART Initialization

1. To initialize the FlexIO UART driver, call the `FLEXIO_UART_DRV_Init()` function and pass the instance number of the FlexIO peripheral, memory for the run-time state structure, and a pointer to the user configuration structure. For example, to use FlexIO0 pass a value of 0 to the initialization function.
2. Then, pass the memory for the run-time state structure.
3. Finally, pass a user configuration structure of the type `flexio_uart_userconfig_t` as shown here:

```
// FlexIO UART configuration structure
typedef struct flexio_uart_userconfig{
 uint32_t baudRate;
 flexio_uart_bit_count_per_char_t bitCounter;
 flexio_uart_mode_t uartMode;
 flexio_uart_hwconfig_t txConfig;
 flexio_uart_hwconfig_t rxConfig;
}flexio_uart_userconfig_t;
```

## FlexIO UART peripheral driver

Typically, the `flexio_uart_userconfig` instantiation is configured as 8-bit-char(8-n-1) with a 9600 bps baud rate. The `flexio_uart_userconfig` instantiation can be easily modified to configure the FlexIO UART peripheral driver either to a different baud rate, character transfer features or using different FlexIO hardware resource. This is an example code to set up a user FlexIO UART configuration instantiation:

```
flexio_uart_userconfig_t uartConfig;
uartConfig.baudRate = 9600;
uartConfig.bitCountPerChar = kUart8BitsPerChar;
uartConfig.uartMode = flexioUART_TxRx;
uartConfig.txConfig.pinIdx = 0;
uartConfig.txConfig.shifterIdx = 0;
uartConfig.txConfig.timerIdx = 0;
uartConfig.rxConfig.pinIdx = 1;
uartConfig.rxConfig.shifterIdx = 1;
uartConfig.rxConfig.timerIdx = 1;
```

This example shows how to call the `FLEXIO_UART_DRV_Init()` given the user configuration structure and the FlexIO instance 0.

```
uint32_t flexioInstance = 0;
flexio_uart_state_t uartState; // user provides memory for the driver state structure

FLEXIO_UART_DRV_Init(flexioInstance, &uartState, &uartConfig);
```

### 28.3.5 FLEXIO UART Transfers

The driver implements transmit and receive functions to transfer buffers of data in blocking and non-blocking modes.

The non-blocking transmit and receive functions include the `FLEXIO_UART_DRV_SendData()` and `FLEXIO_UART_DRV_ReceiveData()` functions.

The blocking (async) transmit and receive functions include the `FLEXIO_UART_DRV_SendDataBlocking()` and `FLEXIO_UART_DRV_ReceiveDataBlocking()` functions.

Ensure that data is consistent when there is cache in memory and when using DMA to transfer data. In other words, when reading the data from memory, ensure that data from or to the memory device is not cached.

In all cases mentioned here, the functions are interrupt-driven.

This code example shows how to use the functions, assuming that the FlexIO simulated UART module has been initialized as described previously in the Initialization Section.

For blocking transfer functions transmit and receive:

```
uint8_t sourceBuff[26] = {0}; // sourceBuff can be filled out with desired data
uint8_t readBuffer[10] = {0}; // readBuffer gets filled

uint32_t byteCount = sizeof(sourceBuff);
uint32_t rxRemainingSize = sizeof(readBuffer);

// For each use there, set timeout as "1"
// uartState is the run-time state. Pass in memory for this
```

```
// declared previously in the initialization chapter
FLEXIO_UART_DRV_SendDataBlocking(uartState, sourceBuff, byteCount, 1); //
 Function won't return until transmit is complete
FLEXIO_UART_DRV_ReceiveDataBlocking(uartState, readBuffer, 1,
 timeoutValue); // Function won't return until it receives all data
```

For non-blocking (async) transfer functions transmit and receive:

```
uint8_t *pTxBuff;
uint8_t rxBuff[10];
uint32_t txBytesRemaining, rxBytesRemaining;

// Assume pTxBuff and txSize have been initialized
FLEXIO_UART_DRV_SendData(uartState, pTxBuff, txSize);

// Check on status of transmit and wait until done; The code can do something else and
// check back later
while (FLEXIO_UART_DRV_GetTransmitStatus(uartState, &txBytesRemaining) ==
 kStatus_FlexIO_UART_TxBusy);

// For receive, assume rxBuff is set up to receive data and rxSize is initialized
FLEXIO_UART_DRV_ReceiveData(uartState, rxBuff, rxSize);

// Check on status of receive and wait until done; The code can do something else and
// check back later
while (FLEXIO_UART_DRV_GetReceiveStatus(uartState, &rxBytesRemaining) ==
 kStatus_FlexIO_UART_RxBusy);
```

`kFlexIOUart6BitsPerChar = 6U`,  
`kFlexIOUart7BitsPerChar = 7U`,  
`kFlexIOUart8BitsPerChar = 8U` }

*FlexIO UART number of bits in a character:*

- enum `flexio_uart_mode_t` {  
`flexioUART_TxOnly = 0x0U`,  
`flexioUART_RxOnly = 0x1U`,  
`flexioUART_TxRx = 0x2U` }

*FlexIO UART mode.*

## FlexIO UART DMA Driver

- `flexio_uart_status_t FLEXIO_UART_DRV_DmaInit` (`uint32_t` instance, `flexio_uart_dmastate_t *uartDmaState`, `const flexio_uartdma_userconfig_t *uartDmaConfig`)  
*Initializes a FlexIO-simulated UART device to work with DMA.*
- `void FLEXIO_UART_DRV_DmaDeinit` (`flexio_uart_dmastate_t *uartDmaState`)  
*Shuts down the FlexIO UART.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaSendDataBlocking` (`flexio_uart_dmastate_t *uartDmaState`, `const uint8_t *txBuff`, `uint32_t txSize`, `uint32_t timeout`)  
*Sends (transmits) data out through the FlexIO-simulated UART-DMA module using a blocking method.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaSendData` (`flexio_uart_dmastate_t *uartDmaState`, `const uint8_t *txBuff`, `uint32_t txSize`)  
*Sends (transmits) data through the FlexIO-simulated UART-DMA module using a non-blocking method.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaGetTransmitStatus` (`flexio_uart_dmastate_t *uartDmaState`, `uint32_t *bytesRemaining`)  
*Returns whether the previous FlexIO-simulated UART-DMA transmit has finished.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaAbortSendingData` (`flexio_uart_dmastate_t *uartDmaState`)  
*Terminates a non-blocking FlexIO-simulated UART-DMA transmission early.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaReceiveDataBlocking` (`flexio_uart_dmastate_t *uartDmaState`, `uint8_t *rxBuff`, `uint32_t rxSize`, `uint32_t timeout`)  
*Gets (receives) data from the FlexIO-simulated UART-DMA module using a blocking method.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaReceiveData` (`flexio_uart_dmastate_t *uartDmaState`, `uint8_t *rxBuff`, `uint32_t rxSize`)  
*Gets (receives) data from the FlexIO-simulated UART-DMA module using a non-blocking method.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaGetReceiveStatus` (`flexio_uart_dmastate_t *uartDmaState`, `uint32_t *bytesRemaining`)  
*Returns whether the previous FlexIO-simulated UART-DMA receive is complete.*
- `flexio_uart_status_t FLEXIO_UART_DRV_DmaAbortReceivingData` (`flexio_uart_dmastate_t *uartDmaState`)  
*Terminates a non-blocking FlexIO-simulated UART-DMA receive early.*

## 28.3.6 Data Structure Documentation

### 28.3.6.1 struct flexio\_uart\_dmastate\_t

#### Data Fields

- volatile bool `isTxBusy`  
*True if there is an active transmit.*
- volatile bool `isRxBusy`  
*True if there is an active receive.*
- volatile bool `isTxBlocking`  
*True if transmit is blocking transaction.*
- volatile bool `isRxBlocking`  
*True if receive is blocking transaction.*
- `semaphore_t txIrqSync`  
*Used to wait for ISR to complete its TX business.*
- `semaphore_t rxIrqSync`  
*Used to wait for ISR to complete its RX business.*
- `dma_channel_t dmaUartTx`  
*DMA channel used for send.*
- `dma_channel_t dmaUartRx`  
*DMA channel used for receive.*

**28.3.6.1.0.124 Field Documentation**

- 28.3.6.1.0.124.1** `volatile bool flexio_uart_dmastate_t::isTxBusy`
- 28.3.6.1.0.124.2** `volatile bool flexio_uart_dmastate_t::isRxBusy`
- 28.3.6.1.0.124.3** `volatile bool flexio_uart_dmastate_t::isTxBlocking`
- 28.3.6.1.0.124.4** `volatile bool flexio_uart_dmastate_t::isRxBlocking`
- 28.3.6.1.0.124.5** `semaphore_t flexio_uart_dmastate_t::txIrqSync`
- 28.3.6.1.0.124.6** `semaphore_t flexio_uart_dmastate_t::rxIrqSync`

- 28.3.6.1.0.124.8** `dma_channel_t flexio_uart_dmastate_t::dmaUartRx`

**28.3.6.2 struct flexio\_uartdma\_userconfig\_t**

Use an instance of this structure with the [FLEXIO\\_UART\\_DRV\\_DmaInit\(\)](#) function. This enables configuration of the most common settings of the UART peripheral with a single function call. Settings include: UART baud rate, UART parity mode: disabled (default), or even or odd, the number of stop bits, and the number of bits per data word.

**Data Fields**

- `uint32_t baudRate`  
*UART baud rate.*
- `flexio_uart_bit_count_per_char_t bitCountPerChar`  
*number of bits, 5/6/7/8 bits configurable*
- `flexio_uart_mode_t uartMode`  
*FlexIO UART working modes: Tx only, Rx only, or both.*
- `flexio_uart_hwconfig_t txConfig`  
*FlexIO UART TX device hardware resource configuration.*
- `flexio_uart_hwconfig_t rxConfig`  
*FlexIO UART RX device hardware resource configuration.*

**28.3.6.3 struct flexio\_uart\_userconfig\_t**

Use an instance of this structure with the [FLEXIO\\_UART\\_DRV\\_Init\(\)](#) function. This enables configuration of the settings of the FlexIO UART peripheral with a single function call. Settings include: UART baud rate, the number of bits per data word, FlexIO UART mode, TX hardware resource and Rx hardware resource.

## FlexIO UART peripheral driver

### Data Fields

- uint32\_t [baudRate](#)  
*UART baud rate.*
- [flexio\\_uart\\_bit\\_count\\_per\\_char\\_t](#) [bitCounter](#)  
*number of bits, 5/6/7/8 bits configurable*
- [flexio\\_uart\\_mode\\_t](#) [uartMode](#)  
*FLEXIO UART working modes: Tx Only, Rx Only or both.*
- [flexio\\_uart\\_hwconfig\\_t](#) [txConfig](#)  
*FLEXIO UART TX device hardware resource config.*
- [flexio\\_uart\\_hwconfig\\_t](#) [rxConfig](#)  
*FLEXIO UART RX device hardware resource config.*

### 28.3.6.4 struct flexio\_uart\_state\_t

This structure holds data that are used by the FlexIO UART peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. The user passes in the memory for the run-time state structure and the FlexIO UART driver fills out the members.

### Data Fields

- volatile bool [isTxBlocking](#)  
*True if transmit is blocking transaction.*
- volatile bool [isRxBlocking](#)  
*True if receive is blocking transaction.*
- [semaphore\\_t](#) [txIrqSync](#)  
*Used to wait for ISR to complete its TX business.*
- [semaphore\\_t](#) [rxIrqSync](#)  
*Used to wait for ISR to complete its RX business.*
- [flexio\\_uart\\_rx\\_callback\\_t](#) [rxCallback](#)  
*Callback to invoke after receiving byte.*
- void \* [rxCallbackParam](#)  
*Receive callback parameter pointer.*

**28.3.6.4.0.125 Field Documentation****28.3.6.4.0.125.1** `volatile bool flexio_uart_state_t::isTxBlocking`**28.3.6.4.0.125.2** `volatile bool flexio_uart_state_t::isRxBlocking`**28.3.6.4.0.125.3** `semaphore_t flexio_uart_state_t::txIrqSync`**28.3.6.4.0.125.4** `semaphore_t flexio_uart_state_t::rxIrqSync`**28.3.6.4.0.125.5** `flexio_uart_rx_callback_t flexio_uart_state_t::rxCallback`**28.3.6.4.0.125.6** `void* flexio_uart_state_t::rxCallbackParam`**28.3.6.5 struct flexio\_uartedma\_userconfig\_t**

Use an instance of this structure with the [FLEXIO\\_UART\\_DRV\\_Init\(\)](#) function to enable configuration of the settings of the FlexIO UART peripheral with a single function call. Settings include: UART baud rate, the number of bits per data word, FlexIO UART mode, transmit hardware resource and receive hardware resource.

**28.3.6.6 struct flexio\_uart\_edmastate\_t**

This structure holds data that is used by the FlexIO UART peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. The user passes in the memory for the run-time state structure and the FlexIO UART driver fills out the members.

**Data Fields**

- `volatile bool isTxBlocking`  
*True if transmit is blocking transaction.*
- `volatile bool isRxBlocking`  
*True if receive is blocking transaction.*
- `semaphore_t txIrqSync`  
*Used to wait for ISR to complete the transmit.*
- `semaphore_t rxIrqSync`  
*Used to wait for ISR to complete the receive.*
- `edma_chn_state_t edmaUartTx`  
*Structure definition for the eDMA channel.*
- `edma_chn_state_t edmaUartRx`  
*Structure definition for the eDMA channel.*

## FlexIO UART peripheral driver

### 28.3.6.6.0.126 Field Documentation

28.3.6.6.0.126.1 `volatile bool flexio_uart_edmastate_t::isTxBlocking`

28.3.6.6.0.126.2 `volatile bool flexio_uart_edmastate_t::isRxBlocking`

28.3.6.6.0.126.3 `semaphore_t flexio_uart_edmastate_t::txIrqSync`

28.3.6.6.0.126.4 `semaphore_t flexio_uart_edmastate_t::rxIrqSync`

### 28.3.6.7 struct `flexio_uart_hwconfig_t`

These constants define the hardware resource used by the FlexIO UART transmit/receive device and include the external pin and internal shifter and timer.

#### Data Fields

- `uint32_t pinIdx`  
*Data line pin.*
- `uint32_t shifterIdx`  
*Shifter.*
- `uint32_t timerIdx`  
*Timer.*

## 28.3.7 Enumeration Type Documentation

### 28.3.7.1 enum `flexio_uart_status_t`

### 28.3.7.2 enum `flexio_uart_bit_count_per_char_t`

These constants define the number of allowable data bits per UART character. Note, check the UART documentation to determine if the desired UART baseAddr supports the desired number of data bits per UART character.

Enumerator

- kFlexIOUart5BitsPerChar*** 5-bit data characters
- kFlexIOUart6BitsPerChar*** 6-bit data characters
- kFlexIOUart7BitsPerChar*** 7-bit data characters
- kFlexIOUart8BitsPerChar*** 8-bit data characters

### 28.3.7.3 enum `flexio_uart_mode_t`

These constants define the operation mode of FlexIO UART: Only enable transmit, only enable receive, or use both.

### Enumerator

*flexioUART\_TxOnly* Transmit mode only.  
*flexioUART\_RxOnly* Receive mode only.  
*flexioUART\_TxRx* Both modes.

## 28.3.8 Function Documentation

### 28.3.8.1 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaInit ( uint32\_t instance, flexio\_uart\_dmastate\_t \* uartDmaState, const flexio\_uartdma\_userconfig\_t \* uartDmaConfig )

This function initializes the run-time state structure to keep track of the on-going transfers and the module to user-defined settings and default settings. It also configures the underlying FlexIO pin, shifter, and timer resource, and enables the FlexIO simulated UART module DMA interrupt. This example shows how to set up the flexio\_uartdma\_state\_t and the flexio\_uartdma\_userconfig\_t parameters and how to call the FLEXIO\_UART\_DRV\_DmaInit function by passing in these parameters:

```
flexio_uartdma_userconfig_t uartDmaConfig;
uartDmaConfig.baudRate = 9600;
uartDmaConfig.bitCountPerChar = kUart8BitsPerChar;
uartDmaConfig.uartMode = flexioUART_TxRx;
```

### Parameters

|                      |                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>      | The FlexIO instance number.                                                                                                                                                                                                                                     |
| <i>uartDmaState</i>  | A pointer to the global FlexIO UART driver state structure memory. The user passes in the memory for the run-time state structure. The FlexIO UART driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>uartDmaConfig</i> | The user configuration structure of type flexio_uartdma_userconfig_t. The user populates the members of this structure and passes the pointer of this structure to this function.                                                                               |

### Returns

An error code or kStatus\_FlexIO\_UART\_Success.

### 28.3.8.2 void FLEXIO\_UART\_DRV\_DmaDeinit ( flexio\_uart\_dmastate\_t \* uartDmaState )

This function disables the FlexIO-simulated UART-DMA trigger.

## FlexIO UART peripheral driver

### Parameters

|                     |                                                  |
|---------------------|--------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART. |
|---------------------|--------------------------------------------------|

### 28.3.8.3 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaSendDataBlocking ( flexio\_uart\_dmastate\_t \* *uartDmaState*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout* )

### Parameters

|                     |                                                                         |
|---------------------|-------------------------------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>txBuff</i>       | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>       | The number of bytes to send.                                            |
| <i>timeout</i>      | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or kStatus\_FlexIO\_UART\_Success.

### 28.3.8.4 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaSendData ( flexio\_uart\_dmastate\_t \* *uartDmaState*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )

### Parameters

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART.                    |
| <i>txBuff</i>       | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>       | The number of bytes to send.                                        |

### Returns

An error code or kStatus\_FlexIO\_UART\_Success.

### 28.3.8.5 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaGetTransmitStatus ( flexio\_uart\_dmastate\_t \* *uartDmaState*, uint32\_t \* *bytesRemaining* )

### Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>uartDmaState</i>    | The run-time structure of FlexIO-simulated UART.                                                           |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### Return values

|                                     |                                                                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_UART_-Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_UART_-TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 28.3.8.6 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaAbortSendingData ( flexio\_uart\_dmastate\_t \* uartDmaState )

#### Parameters

|                     |                                                  |
|---------------------|--------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART. |
|---------------------|--------------------------------------------------|

#### Returns

An error code or `kStatus_FlexIO_UART_Success`.

#### Return values

|                                                  |                                           |
|--------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_UART_-Success</i>              | The transmit was successful.              |
| <i>kStatus_FlexIO_UART_-NoTransmitInProgress</i> | No transmission is currently in progress. |

### 28.3.8.7 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaReceiveDataBlocking ( flexio\_uart\_dmastate\_t \* uartDmaState, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )

## FlexIO UART peripheral driver

### Parameters

|                     |                                                                         |
|---------------------|-------------------------------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>rxBuff</i>       | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>       | The number of bytes to receive.                                         |
| <i>timeout</i>      | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### 28.3.8.8 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaReceiveData ( flexio\_uart\_dmastate\_t \* uartDmaState, uint8\_t \* rxBuff, uint32\_t rxSize )

### Parameters

|                     |                                                                    |
|---------------------|--------------------------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART.                   |
| <i>rxBuff</i>       | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>       | The number of bytes to receive.                                    |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### 28.3.8.9 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaGetReceiveStatus ( flexio\_uart\_dmastate\_t \* uartDmaState, uint32\_t \* bytesRemaining )

### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>uartDmaState</i>    | The run-time structure of FlexIO-simulated UART.                                                                        |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

Returns

An error code or `kStatus_FlexIO_UART_Success`.

Return values

|                                           |                                                                                                                                |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_UART_ -<br/>Success</i> | The receive has completed successfully.                                                                                        |
| <i>kStatus_FlexIO_UART_ -<br/>RxBusy</i>  | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

### 28.3.8.10 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_DmaAbortReceivingData ( flexio\_uart\_dmastate\_t \* uartDmaState )

Parameters

|                     |                                                  |
|---------------------|--------------------------------------------------|
| <i>uartDmaState</i> | The run-time structure of FlexIO-simulated UART. |
|---------------------|--------------------------------------------------|

Returns

An error code or `kStatus_UART_Success`.

Return values

|                                                        |                                      |
|--------------------------------------------------------|--------------------------------------|
| <i>kStatus_FlexIO_UART_ -<br/>Success</i>              | The receive was successful.          |
| <i>kStatus_FlexIO_UART_ -<br/>NoTransmitInProgress</i> | No receive is currently in progress. |

### 28.3.8.11 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_Init ( uint32\_t instance, flexio\_uart\_state\_t \* uartState, const flexio\_uart\_userconfig\_t \* uartConfig )

This function initializes the run-time state structure to keep track of the on-going transfers and the module to user-defined settings and default settings. It also configures the underlying FlexIO pin, shifter, and timer resource, and enables the FlexIO simulated UART module interrupt. This example shows how to set up the `flexio_uart_state_t` and the `flexio_uart_userconfig_t` parameters and how to call the `FLEXIO_UART_DRV_Init` function by passing in these parameters:

```
flexio_uart_userconfig_t uartConfig;
uartConfig.baudRate = 9600;
uartConfig.bitCountPerChar = kUart8BitsPerChar;
uartConfig.uartMode = flexioUART_TxRx;
```

## FlexIO UART peripheral driver

### Parameters

|                   |                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>   | The FlexIO instance number.                                                                                                                                                                                                                                      |
| <i>uartState</i>  | A pointer to the global FlexIOs UART driver state structure memory. The user passes in the memory for the run-time state structure. The FlexIO UART driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>uartConfig</i> | The user configuration structure of type <a href="#">flexio_uart_userconfig_t</a> . The user populates the members of this structure and passes the pointer of this structure to this function.                                                                  |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### 28.3.8.12 void FLEXIO\_UART\_DRV\_Deinit ( flexio\_uart\_state\_t \* *uartState* )

This function disables the FlexIO-simulated UART trigger.

### Parameters

|                  |                                                  |
|------------------|--------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART. |
|------------------|--------------------------------------------------|

### 28.3.8.13 flexio\_uart\_rx\_callback\_t FLEXIO\_UART\_DRV\_InstallRxCallback ( flexio\_uart\_state\_t \* *uartState*, flexio\_uart\_rx\_callback\_t *function*, uint8\_t \* *rxBuff*, void \* *callbackParam*, bool *alwaysEnableRxIrq* )

### Note

Once a callback is installed, it bypasses the UART driver logic. Therefore, the callback needs to handle the `rxBuff` and `rxSize` indexes.

### Parameters

|                  |                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART.                                                      |
| <i>function</i>  | The UART receive callback function.                                                                   |
| <i>rxBuff</i>    | The receive buffer used inside IRQHandler. This buffer must be kept as long as the callback is alive. |

|                           |                                              |
|---------------------------|----------------------------------------------|
| <i>callbackParam</i>      | The UART receive callback parameter pointer. |
| <i>alwaysEnable-RxIrq</i> | Whether always enable Rx IRQ or not.         |

Returns

Former UART receive callback function pointer.

**28.3.8.14 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_SendDataBlocking ( flexio\_uart\_state\_t \* *uartState*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout* )**

Parameters

|                  |                                                                         |
|------------------|-------------------------------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>txBuff</i>    | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>    | The number of bytes to send.                                            |
| <i>timeout</i>   | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or kStatus\_FlexIO\_UART\_Success.

**28.3.8.15 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_SendData ( flexio\_uart\_state\_t \* *uartState*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )**

Parameters

|                  |                                                                     |
|------------------|---------------------------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART.                    |
| <i>txBuff</i>    | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>    | The number of bytes to send.                                        |

Returns

An error code or kStatus\_FlexIO\_UART\_Success.

**28.3.8.16 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_GetTransmitStatus ( flexio\_uart\_state\_t \* *uartState*, uint32\_t \* *bytesRemaining* )**

## FlexIO UART peripheral driver

### Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>uartState</i>       | The run-time structure of FlexIO-simulated UART.                                                           |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### Return values

|                                    |                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_UART_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_UART_TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 28.3.8.17 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_AbortSendingData ( flexio\_uart\_state\_t \* *uartState* )

#### Parameters

|                  |                                                  |
|------------------|--------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART. |
|------------------|--------------------------------------------------|

#### Returns

An error code or `kStatus_FlexIO_UART_Success`.

#### Return values

|                                                 |                                           |
|-------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_UART_Success</i>              | The transmit was successful.              |
| <i>kStatus_FlexIO_UART_NoTransmitInProgress</i> | No transmission is currently in progress. |

### 28.3.8.18 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_ReceiveDataBlocking ( flexio\_uart\_state\_t \* *uartState*, uint8\_t \* *rxBuff*, uint32\_t *rxSize*, uint32\_t *timeout* )

### Parameters

|                  |                                                                         |
|------------------|-------------------------------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>rxBuff</i>    | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>    | The number of bytes to receive.                                         |
| <i>timeout</i>   | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

#### 28.3.8.19 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_ReceiveData ( flexio\_uart\_state\_t \* *uartState*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* )

### Parameters

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART.                   |
| <i>rxBuff</i>    | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>    | The number of bytes to receive.                                    |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

#### 28.3.8.20 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_GetReceiveStatus ( flexio\_uart\_state\_t \* *uartState*, uint32\_t \* *bytesRemaining* )

### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>uartState</i>       | The run-time structure of FlexIO-simulated UART.                                                                        |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

## FlexIO UART peripheral driver

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### Return values

|                                          |                                                                                                                                |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>kStatus_FlexIO_UART_Success</code> | The receive has completed successfully.                                                                                        |
| <code>kStatus_FlexIO_UART_RxBusy</code>  | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

### 28.3.8.21 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_AbortReceivingData ( flexio\_uart\_state\_t \* *uartState* )

#### Parameters

|                  |                                                  |
|------------------|--------------------------------------------------|
| <i>uartState</i> | The run-time structure of FlexIO-simulated UART. |
|------------------|--------------------------------------------------|

### Returns

An error code or `kStatus_UART_Success`.

### Return values

|                                                       |                                      |
|-------------------------------------------------------|--------------------------------------|
| <code>kStatus_FlexIO_UART_Success</code>              | The receive was successful.          |
| <code>kStatus_FlexIO_UART_NoTransmitInProgress</code> | No receive is currently in progress. |

### 28.3.8.22 void FLEXIO\_UART\_DRV\_TX\_IRQHandler ( void \* *param* )

#### Parameters

---

|              |                                                  |
|--------------|--------------------------------------------------|
| <i>param</i> | The run-time structure of FlexIO-simulated UART. |
|--------------|--------------------------------------------------|

**28.3.8.23 void FLEXIO\_UART\_DRV\_RX\_IRQHandler ( void \* *param* )**

Parameters

|              |                                                  |
|--------------|--------------------------------------------------|
| <i>param</i> | The run-time structure of FlexIO-simulated UART. |
|--------------|--------------------------------------------------|

**28.3.8.24 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaInit ( uint32\_t *instance*, flexio\_uart\_edmastate\_t \* *uartEdmaState*, const flexio\_uartedma\_userconfig\_t \* *uartEdmaConfig* )**

This function initializes the run-time state structure to keep track of the on-going transfers, initializes the module to user-defined settings and default settings, configures underlying FlexIO pin, shifter, and timer resource, and enables the FlexIO-simulated UART module eDMA interrupt. This example shows how to set up the flexio\_uartedma\_state\_t and the flexio\_uartedma\_userconfig\_t parameters and how to call the FLEXIO\_UART\_DRV\_EdmaInit function by passing in these parameters:

```
flexio_uartedma_userconfig_t uartEdmaConfig;
uartEdmaConfig.baudRate = 9600;
uartEdmaConfig.bitCountPerChar = kUart8BitsPerChar;
uartEdmaConfig.uartMode = flexioUART_TxRx;
```

Parameters

|                        |                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The FlexIO instance number.                                                                                                                                                                                                                                     |
| <i>uartEdmaState</i>   | A pointer to the global FlexIO UART driver state structure memory. The user passes in the memory for the run-time state structure. The FlexIO UART driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>uartEdma-Config</i> | The user configuration structure of type flexio_uartedma_userconfig_t. The user populates the members of this structure and passes the pointer of this structure to this function.                                                                              |

Returns

An error code or kStatus\_FlexIO\_UART\_Success.

**28.3.8.25 void FLEXIO\_UART\_DRV\_EdmaDeinit ( flexio\_uart\_edmastate\_t \* *uartEdmaState* )**

This function disables the FlexIO-simulated UART eDMA trigger.

## FlexIO UART peripheral driver

### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART. |
|----------------------|--------------------------------------------------|

### 28.3.8.26 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaSendDataBlocking ( flexio\_uart\_edmastate\_t \* *uartEdmaState*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout* )

### Parameters

|                      |                                                                         |
|----------------------|-------------------------------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>txBuff</i>        | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>        | The number of bytes to send.                                            |
| <i>timeout</i>       | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or kStatus\_FlexIO\_UART\_Success.

### 28.3.8.27 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaSendData ( flexio\_uart\_edmastate\_t \* *uartEdmaState*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )

### Parameters

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART.                    |
| <i>txBuff</i>        | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>        | The number of bytes to send.                                        |

### Returns

An error code or kStatus\_FlexIO\_UART\_Success.

### 28.3.8.28 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaGetTransmitStatus ( flexio\_uart\_edmastate\_t \* *uartEdmaState*, uint32\_t \* *bytesRemaining* )

### Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>uartEdmaState</i>   | The run-time structure of FlexIO-simulated UART.                                                           |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### Return values

|                                     |                                                                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_FlexIO_UART_-Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_FlexIO_UART_-TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 28.3.8.29 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaAbortSendingData ( flexio\_uart\_edmastate\_t \* uartEdmaState )

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART. |
|----------------------|--------------------------------------------------|

#### Returns

An error code or `kStatus_FlexIO_UART_Success`.

#### Return values

|                                                  |                                           |
|--------------------------------------------------|-------------------------------------------|
| <i>kStatus_FlexIO_UART_-Success</i>              | The transmit was successful.              |
| <i>kStatus_FlexIO_UART_-NoTransmitInProgress</i> | No transmission is currently in progress. |

### 28.3.8.30 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaReceiveDataBlocking ( flexio\_uart\_edmastate\_t \* uartEdmaState, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )

## FlexIO UART peripheral driver

### Parameters

|                      |                                                                         |
|----------------------|-------------------------------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART.                        |
| <i>rxBuff</i>        | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>        | The number of bytes to receive.                                         |
| <i>timeout</i>       | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### 28.3.8.31 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaReceiveData ( flexio\_uart\_edmastate\_t \* uartEdmaState, uint8\_t \* rxBuff, uint32\_t rxSize )

### Parameters

|                      |                                                                    |
|----------------------|--------------------------------------------------------------------|
| <i>uartEdmaState</i> | The run-time structure of FlexIO-simulated UART.                   |
| <i>rxBuff</i>        | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>        | The number of bytes to receive.                                    |

### Returns

An error code or `kStatus_FlexIO_UART_Success`.

### 28.3.8.32 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaGetReceiveStatus ( flexio\_uart\_edmastate\_t \* uartEdmaState, uint32\_t \* bytesRemaining )

### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>uartEdmaState</i>   | The run-time structure of FlexIO-simulated UART.                                                                        |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

Returns

An error code or `kStatus_FlexIO_UART_Success`.

Return values

|                                          |                                                                                                                                |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>kStatus_FlexIO_UART_Success</code> | The receive has completed successfully.                                                                                        |
| <code>kStatus_FlexIO_UART_RxBusy</code>  | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

**28.3.8.33 flexio\_uart\_status\_t FLEXIO\_UART\_DRV\_EdmaAbortReceivingData ( flexio\_uart\_edmastate\_t \* uartEdmaState )**

Parameters

|                            |                                                  |
|----------------------------|--------------------------------------------------|
| <code>uartEdmaState</code> | The run-time structure of FlexIO-simulated UART. |
|----------------------------|--------------------------------------------------|

Returns

An error code or `kStatus_UART_Success`.

Return values

|                                                       |                                      |
|-------------------------------------------------------|--------------------------------------|
| <code>kStatus_FlexIO_UART_Success</code>              | The receive was successful.          |
| <code>kStatus_FlexIO_UART_NoTransmitInProgress</code> | No receive is currently in progress. |

## Chapter 29

### FlexTimer (FTM)

#### 29.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the FlexTimer (FTM) block of Kinetis devices.

#### Modules

- [FlexTimer HAL driver](#)
- [FlexTimer Peripheral Driver](#)

## FlexTimer HAL driver

### 29.2 FlexTimer HAL driver

#### 29.2.1 Overview

This section describes the programming interface of the FlexTimer HAL driver.

#### Data Structures

- union [ftm\\_edge\\_mode\\_t](#)  
*FlexTimer edge mode. [More...](#)*
- struct [ftm\\_pwm\\_param\\_t](#)  
*FlexTimer driver PWM parameter. [More...](#)*
- struct [ftm\\_dual\\_edge\\_capture\\_param\\_t](#)  
*FlexTimer Dual Edge Capture parameters. [More...](#)*
- struct [ftm\\_phase\\_params\\_t](#)  
*FlexTimer quadrature decode phase parameters. [More...](#)*

#### Macros

- #define [CHAN0\\_IDX](#) (0U)  
*Channel number for CHAN0.*
- #define [CHAN1\\_IDX](#) (1U)  
*Channel number for CHAN1.*
- #define [CHAN2\\_IDX](#) (2U)  
*Channel number for CHAN2.*
- #define [CHAN3\\_IDX](#) (3U)  
*Channel number for CHAN3.*
- #define [CHAN4\\_IDX](#) (4U)  
*Channel number for CHAN4.*
- #define [CHAN5\\_IDX](#) (5U)  
*Channel number for CHAN5.*
- #define [CHAN6\\_IDX](#) (6U)  
*Channel number for CHAN6.*
- #define [CHAN7\\_IDX](#) (7U)  
*Channel number for CHAN7.*

#### Enumerations

- enum [ftm\\_clock\\_source\\_t](#)  
*FlexTimer clock source selection.*
- enum [ftm\\_counting\\_mode\\_t](#)  
*FlexTimer counting mode selection.*
- enum [ftm\\_clock\\_ps\\_t](#)  
*FlexTimer pre-scaler factor selection for the clock source.*
- enum [ftm\\_deadtime\\_ps\\_t](#)  
*FlexTimer pre-scaler factor for the deadtime insertion.*
- enum [ftm\\_config\\_mode\\_t](#)

- FlexTimer operation mode, capture, output, dual.*

  - enum `ftm_input_capture_edge_mode_t`  
*FlexTimer input capture edge mode, rising edge, or falling edge.*
  - enum `ftm_output_compare_edge_mode_t`  
*FlexTimer output compare edge mode.*
  - enum `ftm_pwm_edge_mode_t`  
*FlexTimer PWM output pulse mode, high-true or low-true on match up.*
  - enum `ftm_dual_capture_edge_mode_t`  
*FlexTimer dual capture edge mode, one shot or continuous.*
  - enum `ftm_quad_decode_mode_t`  
*FlexTimer quadrature decode modes, phase encode or count and direction mode.*
  - enum `ftm_quad_phase_polarity_t` {  
`kFtmQuadPhaseNormal` = 0,  
`kFtmQuadPhaseInvert` }
  - FlexTimer quadrature phase polarities, normal or inverted polarity.*
  - enum `ftm_sync_method_t`  
*FlexTimer sync options to update registers with buffer.*
  - enum `ftm_bdm_mode_t` {  
`kFtmBdmMode_00` = 0,  
`kFtmBdmMode_01`,  
`kFtmBdmMode_10`,  
`kFtmBdmMode_11` }
  - Options for the FlexTimer behaviour in BDM Mode.*
  - enum `ftm_status_t` {  
`kStatusFtmSuccess` = 0U,  
`kStatusFtmError` = 1U }
  - FTM status.*

## Functions

- static void `FTM_HAL_SetClockSource` (FTM\_Type \*ftmBase, `ftm_clock_source_t` clock)  
*Sets the FTM clock source.*
- static uint8\_t `FTM_HAL_GetClockSource` (FTM\_Type \*ftmBase)  
*Reads the FTM clock source.*
- static void `FTM_HAL_SetClockPs` (FTM\_Type \*ftmBase, `ftm_clock_ps_t` ps)  
*Sets the FTM clock divider.*
- static uint8\_t `FTM_HAL_GetClockPs` (FTM\_Type \*ftmBase)  
*Reads the FTM clock divider.*
- static void `FTM_HAL_EnableTimerOverflowInt` (FTM\_Type \*ftmBase)  
*Enables the FTM peripheral timer overflow interrupt.*
- static void `FTM_HAL_DisableTimerOverflowInt` (FTM\_Type \*ftmBase)  
*Disables the FTM peripheral timer overflow interrupt.*
- static bool `FTM_HAL_IsOverflowIntEnabled` (FTM\_Type \*ftmBase)  
*Reads the bit that controls enabling the FTM timer overflow interrupt.*
- static void `FTM_HAL_ClearTimerOverflow` (FTM\_Type \*ftmBase)  
*Clears the timer overflow interrupt flag.*
- static bool `FTM_HAL_HasTimerOverflowed` (FTM\_Type \*ftmBase)  
*Returns the FTM peripheral timer overflow interrupt flag.*
- static void `FTM_HAL_SetCpwms` (FTM\_Type \*ftmBase, uint8\_t mode)

## FlexTimer HAL driver

- Sets the FTM center-aligned PWM select.*

  - static void [FTM\\_HAL\\_SetCounter](#) (FTM\_Type \*ftmBase, uint16\_t val)
- Sets the FTM peripheral current counter value.*

  - static uint16\_t [FTM\\_HAL\\_GetCounter](#) (FTM\_Type \*ftmBase)
- Returns the FTM peripheral current counter value.*

  - static void [FTM\\_HAL\\_SetMod](#) (FTM\_Type \*ftmBase, uint16\_t val)
- Sets the FTM peripheral timer modulo value.*

  - static uint16\_t [FTM\\_HAL\\_GetMod](#) (FTM\_Type \*ftmBase)
- Returns the FTM peripheral counter modulo value.*

  - static void [FTM\\_HAL\\_SetCounterInitVal](#) (FTM\_Type \*ftmBase, uint16\_t val)
- Sets the FTM peripheral timer counter initial value.*

  - static uint16\_t [FTM\\_HAL\\_GetCounterInitVal](#) (FTM\_Type \*ftmBase)
- Returns the FTM peripheral counter initial value.*

  - static void [FTM\\_HAL\\_SetChnMSnBAMode](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t selection)
- Sets the FTM peripheral timer channel mode.*

  - static void [FTM\\_HAL\\_SetChnEdgeLevel](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t level)
- Sets the FTM peripheral timer channel edge level.*

  - static uint8\_t [FTM\\_HAL\\_GetChnMode](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Gets the FTM peripheral timer channel mode.*

  - static uint8\_t [FTM\\_HAL\\_GetChnEdgeLevel](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Gets the FTM peripheral timer channel edge level.*

  - static void [FTM\\_HAL\\_SetChnDmaCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool val)
- Enables or disables the FTM peripheral timer channel DMA.*

  - static bool [FTM\\_HAL\\_IsChnDma](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Returns whether the FTM peripheral timer channel DMA is enabled.*

  - static bool [FTM\\_HAL\\_IsChnIntEnabled](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Gets the FTM channel(n) interrupt enabled or not.*

  - static void [FTM\\_HAL\\_EnableChnInt](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Enables the FTM peripheral timer channel(n) interrupt.*

  - static void [FTM\\_HAL\\_DisableChnInt](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Disables the FTM peripheral timer channel(n) interrupt.*

  - static bool [FTM\\_HAL\\_HasChnEventOccurred](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Returns whether any event for the FTM peripheral timer channel has occurred.*

  - static void [FTM\\_HAL\\_ClearChnEventFlag](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Clears the channel flag by writing a 0 to the CHF bit.*

  - static void [FTM\\_HAL\\_SetChnCountVal](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint16\_t val)
- Sets the FTM peripheral timer channel counter value.*

  - static uint16\_t [FTM\\_HAL\\_GetChnCountVal](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Gets the FTM peripheral timer channel counter value.*

  - static uint32\_t [FTM\\_HAL\\_GetChnEventStatus](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Gets the FTM peripheral timer channel event status.*

  - static void [FTM\\_HAL\\_ClearChnEventStatus](#) (FTM\_Type \*ftmBase, uint8\_t channel)
- Clears the FTM peripheral timer all channel event status.*

  - static void [FTM\\_HAL\\_SetOutmaskReg](#) (FTM\_Type \*ftmBase, uint32\_t regVal)
- Writes the provided value to the OUTMASK register.*

  - static void [FTM\\_HAL\\_SetChnOutputMask](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool mask)
- Sets the FTM peripheral timer channel output mask.*

  - static void [FTM\\_HAL\\_SetChnOutputInitStateCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t state)
- Sets the FTM peripheral timer channel output initial state 0 or 1.*

- static void [FTM\\_HAL\\_SetChnOutputPolarityCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t pol)  
*Sets the FTM peripheral timer channel output polarity.*
- static void [FTM\\_HAL\\_SetChnFaultInputPolarityCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t pol)  
*Sets the FTM peripheral timer channel input polarity.*
- static void [FTM\\_HAL\\_EnableFaultInt](#) (FTM\_Type \*ftmBase)  
*Enables the FTM peripheral timer fault interrupt.*
- static void [FTM\\_HAL\\_DisableFaultInt](#) (FTM\_Type \*ftmBase)  
*Disables the FTM peripheral timer fault interrupt.*
- static void [FTM\\_HAL\\_SetFaultControlMode](#) (FTM\_Type \*ftmBase, uint8\_t mode)  
*Defines the FTM fault control mode.*
- static void [FTM\\_HAL\\_SetCaptureTestCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM peripheral timer capture test mode.*
- static void [FTM\\_HAL\\_SetWriteProtectionCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM write protection.*
- static void [FTM\\_HAL\\_Enable](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables the FTM peripheral timer group.*
- static void [FTM\\_HAL\\_SetInitChnOutputCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Initializes the channels output.*
- static void [FTM\\_HAL\\_SetPwmSyncMode](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets the FTM peripheral timer sync mode.*
- static void [FTM\\_HAL\\_SetSoftwareTriggerCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM peripheral timer software trigger.*
- void [FTM\\_HAL\\_SetHardwareSyncTriggerSrc](#) (FTM\_Type \*ftmBase, uint32\_t trigger\_num, bool enable)  
*Sets the FTM peripheral timer hardware trigger.*
- static void [FTM\\_HAL\\_SetOutmaskPwmSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Determines when the OUTMASK register is updated with the value of its buffer.*
- static void [FTM\\_HAL\\_SetCountReinitSyncCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Determines if the FTM counter is re-initialized when the selected trigger for synchronization is detected.*
- static void [FTM\\_HAL\\_SetMaxLoadingCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM peripheral timer maximum loading points.*
- static void [FTM\\_HAL\\_SetMinLoadingCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM peripheral timer minimum loading points.*
- uint32\_t [FTM\\_HAL\\_GetChnPairIndex](#) (uint8\_t channel)  
*Combines the channel control.*
- static void [FTM\\_HAL\\_SetDualChnFaultCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)  
*Enables the FTM peripheral timer channel pair fault control.*
- static void [FTM\\_HAL\\_SetDualChnPwmSyncCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)  
*Enables or disables the FTM peripheral timer channel pair counter PWM sync.*
- static void [FTM\\_HAL\\_SetDualChnDeadtimeCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)  
*Enables or disabled the FTM peripheral timer channel pair deadtime insertion.*
- static void [FTM\\_HAL\\_SetDualChnDecapCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)  
*Enables or disables the FTM peripheral timer channel dual edge capture decap.*
- static void [FTM\\_HAL\\_SetDualEdgeCaptureCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum,

## FlexTimer HAL driver

- bool enable)
  - Enables the FTM peripheral timer dual edge capture mode.*
- static void [FTM\\_HAL\\_SetDualChnCompCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)
  - Enables or disables the FTM peripheral timer channel pair output complement mode.*
- static void [FTM\\_HAL\\_SetDualChnCombineCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool enable)
  - Enables or disables the FTM peripheral timer channel pair output combine mode.*
- static void [FTM\\_HAL\\_SetDeadtimePrescale](#) (FTM\_Type \*ftmBase, [ftm\\_deadtime\\_ps\\_t](#) divider)
  - Sets the FTM deadtime divider.*
- static void [FTM\\_HAL\\_SetDeadtimeCount](#) (FTM\_Type \*ftmBase, uint8\_t count)
  - Sets the FTM deadtime value.*
- static void [FTM\\_HAL\\_SetInitTriggerCmd](#) (FTM\_Type \*ftmBase, bool enable)
  - Enables or disables the generation of the trigger when the FTM counter is equal to the CNTIN register.*
- void [FTM\\_HAL\\_SetChnTriggerCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool val)
  - Enables or disables the generation of the FTM peripheral timer channel trigger.*
- static bool [FTM\\_HAL\\_IsChnTriggerGenerated](#) (FTM\_Type \*ftmBase)
  - Checks whether any channel trigger event has occurred.*
- static uint8\_t [FTM\\_HAL\\_GetDetectedFaultInput](#) (FTM\_Type \*ftmBase)
  - Gets the FTM detected fault input.*
- static bool [FTM\\_HAL\\_IsWriteProtectionEnabled](#) (FTM\_Type \*ftmBase)
  - Checks whether the write protection is enabled.*
- static void [FTM\\_HAL\\_SetQuadDecoderCmd](#) (FTM\_Type \*ftmBase, bool enable)
  - Enables the channel quadrature decoder.*
- static void [FTM\\_HAL\\_SetQuadPhaseAFilterCmd](#) (FTM\_Type \*ftmBase, bool enable)
  - Enables or disables the phase A input filter.*
- static void [FTM\\_HAL\\_SetQuadPhaseBFilterCmd](#) (FTM\_Type \*ftmBase, bool enable)
  - Enables or disables the phase B input filter.*
- static void [FTM\\_HAL\\_SetQuadPhaseAPolarity](#) (FTM\_Type \*ftmBase, [ftm\\_quad\\_phase\\_polarity\\_t](#) mode)
  - Selects polarity for the quadrature decode phase A input.*
- static void [FTM\\_HAL\\_SetQuadPhaseBPolarity](#) (FTM\_Type \*ftmBase, [ftm\\_quad\\_phase\\_polarity\\_t](#) mode)
  - Selects polarity for the quadrature decode phase B input.*
- static void [FTM\\_HAL\\_SetQuadMode](#) (FTM\_Type \*ftmBase, [ftm\\_quad\\_decode\\_mode\\_t](#) quad-Mode)
  - Sets the encoding mode used in quadrature decoding mode.*
- static uint8\_t [FTM\\_HAL\\_GetQuadDir](#) (FTM\_Type \*ftmBase)
  - Gets the FTM counter direction in quadrature mode.*
- static uint8\_t [FTM\\_HAL\\_GetQuadTimerOverflowDir](#) (FTM\_Type \*ftmBase)
  - Gets the timer overflow direction in quadrature mode.*
- void [FTM\\_HAL\\_SetChnInputCaptureFilter](#) (FTM\_Type \*ftmBase, uint8\_t channel, uint8\_t val)
  - Sets the FTM peripheral timer channel input capture filter value.*
- static void [FTM\\_HAL\\_SetFaultInputFilterVal](#) (FTM\_Type \*ftmBase, uint32\_t val)
  - Sets the fault input filter value.*
- static void [FTM\\_HAL\\_SetFaultInputFilterCmd](#) (FTM\_Type \*ftmBase, uint8\_t inputNum, bool val)
  - Enables or disables the fault input filter.*
- static void [FTM\\_HAL\\_SetFaultInputCmd](#) (FTM\_Type \*ftmBase, uint8\_t inputNum, bool val)
  - Enables or disables the fault input.*
- static void [FTM\\_HAL\\_SetDualChnInvertCmd](#) (FTM\_Type \*ftmBase, uint8\_t chnlPairNum, bool

val)

*Enables or disables the channel invert for a channel pair.*

- static void [FTM\\_HAL\\_SetInvctrlReg](#) (FTM\_Type \*ftmBase, uint32\_t regVal)  
*Writes the provided value to the Inverting Control register.*
- static void [FTM\\_HAL\\_SetChnSoftwareCtrlCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool val)  
*Enables or disables the channel software output control.*
- static void [FTM\\_HAL\\_SetChnSoftwareCtrlVal](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool val)  
*Sets the channel software output control value.*
- static void [FTM\\_HAL\\_SetPwmLoadCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the loading of MOD, CNTIN, and CV with values of their write buffer.*
- static void [FTM\\_HAL\\_SetPwmLoadChnSelCmd](#) (FTM\_Type \*ftmBase, uint8\_t channel, bool val)  
*Includes or excludes the channel in the matching process.*
- static void [FTM\\_HAL\\_SetGlobalTimeBaseOutputCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM global time base signal generation to other FTM's.*
- static void [FTM\\_HAL\\_SetGlobalTimeBaseCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Enables or disables the FTM timer global time base.*
- static void [FTM\\_HAL\\_SetBdmMode](#) (FTM\_Type \*ftmBase, [ftm\\_bdm\\_mode\\_t](#) val)  
*Sets the BDM mode.*
- static void [FTM\\_HAL\\_SetTofFreq](#) (FTM\_Type \*ftmBase, uint8\_t val)  
*Sets the FTM timer TOF Frequency.*
- void [FTM\\_HAL\\_SetSyncMode](#) (FTM\_Type \*ftmBase, uint32\_t syncMethod)  
*Sets the FTM register synchronization method.*
- static void [FTM\\_HAL\\_SetSwoctrlHardwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets the sync mode for the FTM SWOCTRL register when using a hardware trigger.*
- static void [FTM\\_HAL\\_SetInvctrlHardwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM INVCTRL register when using a hardware trigger.*
- static void [FTM\\_HAL\\_SetOutmaskHardwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM OUTMASK register when using a hardware trigger.*
- static void [FTM\\_HAL\\_SetModCntrlCvHardwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM MOD, CNTIN and CV registers when using a hardware trigger.*
- static void [FTM\\_HAL\\_SetCounterHardwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM counter register when using a hardware trigger.*
- static void [FTM\\_HAL\\_SetSwoctrlSoftwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM SWOCTRL register when using a software trigger.*
- static void [FTM\\_HAL\\_SetInvctrlSoftwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM INVCTRL register when using a software trigger.*
- static void [FTM\\_HAL\\_SetOutmaskSoftwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM OUTMASK register when using a software trigger.*
- static void [FTM\\_HAL\\_SetModCntrlCvSoftwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets synch mode for FTM MOD, CNTIN, and CV registers when using a software trigger.*
- static void [FTM\\_HAL\\_SetCounterSoftwareSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets sync mode for FTM counter register when using a software trigger.*
- static void [FTM\\_HAL\\_SetPwmSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets the PWM synchronization mode to enhanced or legacy.*
- static void [FTM\\_HAL\\_SetSwoctrlPwmSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets the SWOCTRL register PWM synchronization mode.*
- static void [FTM\\_HAL\\_SetInvctrlPwmSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)  
*Sets the INVCTRL register PWM synchronization mode.*
- static void [FTM\\_HAL\\_SetCntrlPwmSyncModeCmd](#) (FTM\_Type \*ftmBase, bool enable)

## FlexTimer HAL driver

- *Sets the CNTIN register PWM synchronization mode.*
- void [FTM\\_HAL\\_Reset](#) (FTM\_Type \*ftmBase)
- *Resets the FTM registers.*
- void [FTM\\_HAL\\_Init](#) (FTM\_Type \*ftmBase)
- *Initializes the FTM.*
- void [FTM\\_HAL\\_EnablePwmMode](#) (FTM\_Type \*ftmBase, [ftm\\_pwm\\_param\\_t](#) \*config, uint8\_t channel)
- *Enables the FTM timer when it is PWM output mode.*
- void [FTM\\_HAL\\_DisablePwmMode](#) (FTM\_Type \*ftmBase, [ftm\\_pwm\\_param\\_t](#) \*config, uint8\_t channel)
- *Disables the PWM output mode.*

## 29.2.2 Data Structure Documentation

### 29.2.2.1 union [ftm\\_edge\\_mode\\_t](#)

### 29.2.2.2 struct [ftm\\_pwm\\_param\\_t](#)

#### Data Fields

- [ftm\\_config\\_mode\\_t mode](#)  
*FlexTimer PWM operation mode.*
- [ftm\\_pwm\\_edge\\_mode\\_t edgeMode](#)  
*PWM output mode.*
- uint32\_t [uFrequencyHZ](#)  
*PWM period in Hz.*
- uint32\_t [uDutyCyclePercent](#)  
*PWM pulse width, value should be between 0 to 100 0=inactive signal(0% duty cycle)...*
- uint16\_t [uFirstEdgeDelayPercent](#)  
*Used only in combined PWM mode to generate asymmetrical PWM.*

#### 29.2.2.2.0.127 Field Documentation

##### 29.2.2.2.0.127.1 uint32\_t [ftm\\_pwm\\_param\\_t::uDutyCyclePercent](#)

100=active signal (100% duty cycle).

##### 29.2.2.2.0.127.2 uint16\_t [ftm\\_pwm\\_param\\_t::uFirstEdgeDelayPercent](#)

Specifies the delay to the first edge in a PWM period. If unsure please leave as 0, should be specified as percentage of the PWM period

### 29.2.2.3 struct [ftm\\_dual\\_edge\\_capture\\_param\\_t](#)

#### Data Fields

- [ftm\\_dual\\_capture\\_edge\\_mode\\_t mode](#)

- Dual Edge Capture mode: one-shot or continuous.*
  - [ftm\\_input\\_capture\\_edge\\_mode\\_t currChanEdgeMode](#)  
*Input Edge select for Channel n.*
  - [ftm\\_input\\_capture\\_edge\\_mode\\_t nextChanEdgeMode](#)  
*Input Edge select for Channel n + 1.*

#### 29.2.2.4 struct ftm\_phase\_params\_t

##### Data Fields

- bool [kFtmPhaseInputFilter](#)  
*false: disable phase filter, true: enable phase filter*
- uint32\_t [kFtmPhaseFilterVal](#)  
*Filter value, used only if phase input filter is enabled.*
- [ftm\\_quad\\_phase\\_polarity\\_t kFtmPhasePolarity](#)  
*kFtmQuadPhaseNormal or kFtmQuadPhaseInvert*

#### 29.2.3 Macro Definition Documentation

29.2.3.1 #define CHAN0\_IDX (0U)

29.2.3.2 #define CHAN1\_IDX (1U)

29.2.3.3 #define CHAN2\_IDX (2U)

29.2.3.4 #define CHAN3\_IDX (3U)

29.2.3.5 #define CHAN4\_IDX (4U)

29.2.3.6 #define CHAN5\_IDX (5U)

29.2.3.7 #define CHAN6\_IDX (6U)

29.2.3.8 #define CHAN7\_IDX (7U)

#### 29.2.4 Enumeration Type Documentation

29.2.4.1 enum ftm\_output\_compare\_edge\_mode\_t

Toggle, clear or set.

## FlexTimer HAL driver

### 29.2.4.2 enum `ftm_quad_phase_polarity_t`

Enumerator

***kFtmQuadPhaseNormal*** Phase A input signal is not inverted before identifying the rising and falling edges of this signal.

***kFtmQuadPhaseInvert*** Phase A input signal is inverted before identifying the rising and falling edges of this signal.

### 29.2.4.3 enum `ftm_bdm_mode_t`

Enumerator

***kFtmBdmMode\_00*** FTM counter stopped, CH(n)F bit can be set, FTM channels in functional mode, writes to MOD,CNTIN and C(n)V registers bypass the register buffers.

***kFtmBdmMode\_01*** FTM counter stopped, CH(n)F bit is not set, FTM channels outputs are forced to their safe value , writes to MOD,CNTIN and C(n)V registers bypass the register buffers.

***kFtmBdmMode\_10*** FTM counter stopped, CH(n)F bit is not set, FTM channels outputs are frozen when chip enters in BDM mode, writes to MOD,CNTIN and C(n)V registers bypass the register buffers.

***kFtmBdmMode\_11*** FTM counter in functional mode, CH(n)F bit can be set, FTM channels in functional mode, writes to MOD,CNTIN and C(n)V registers is in fully functional mode.

### 29.2.4.4 enum `ftm_status_t`

Enumerator

***kStatusFtmSuccess*** FTM success status.

***kStatusFtmError*** FTM error status.

## 29.2.5 Function Documentation

**29.2.5.1** `static void FTM_HAL_SetClockSource ( FTM_Type * ftmBase,  
ftm_clock_source_t clock ) [inline], [static]`

Parameters

---

|                |                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                  |
| <i>clock</i>   | The FTM peripheral clock selection<br>bits - 00: No clock 01: system clock 10: fixed clock 11: External clock |

**29.2.5.2 static uint8\_t FTM\_HAL\_GetClockSource ( FTM\_Type \* *ftmBase* ) [inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

The FTM clock source selection  
bits - 00: No clock 01: system clock 10: fixed clock 11:External clock

**29.2.5.3 static void FTM\_HAL\_SetClockPs ( FTM\_Type \* *ftmBase*, ftm\_clock\_ps\_t *ps* ) [inline], [static]**

Parameters

|                |                                            |
|----------------|--------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer               |
| <i>ps</i>      | The FTM peripheral clock pre-scale divider |

**29.2.5.4 static uint8\_t FTM\_HAL\_GetClockPs ( FTM\_Type \* *ftmBase* ) [inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

The FTM clock pre-scale divider

**29.2.5.5 static void FTM\_HAL\_EnableTimerOverflowInt ( FTM\_Type \* *ftmBase* ) [inline], [static]**

## FlexTimer HAL driver

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.6 static void FTM\_HAL\_DisableTimerOverflowInt ( FTM\_Type \* *ftmBase* )**  
**[inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.7 static bool FTM\_HAL\_IsOverflowIntEnabled ( FTM\_Type \* *ftmBase* )**  
**[inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

true if overflow interrupt is enabled, false if not

**29.2.5.8 static void FTM\_HAL\_ClearTimerOverflow ( FTM\_Type \* *ftmBase* ) [inline],**  
**[static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.9 static bool FTM\_HAL\_HasTimerOverflowed ( FTM\_Type \* *ftmBase* ) [inline],**  
**[static]**

Parameters

---

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

true if overflow, false if not

**29.2.5.10 static void FTM\_HAL\_SetCpwms ( FTM\_Type \* *ftmBase*, uint8\_t *mode* )**  
**[inline], [static]**

Parameters

|                |                                           |
|----------------|-------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer              |
| <i>mode</i>    | 1:upcounting mode 0:up_down counting mode |

**29.2.5.11 static void FTM\_HAL\_SetCounter ( FTM\_Type \* *ftmBase*, uint16\_t *val* )**  
**[inline], [static]**

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>val</i>     | FTM timer counter value to be set |

**29.2.5.12 static uint16\_t FTM\_HAL\_GetCounter ( FTM\_Type \* *ftmBase* ) [inline],**  
**[static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

current FTM timer counter value

**29.2.5.13 static void FTM\_HAL\_SetMod ( FTM\_Type \* *ftmBase*, uint16\_t *val* )**  
**[inline], [static]**

## FlexTimer HAL driver

### Parameters

|                |                                         |
|----------------|-----------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer            |
| <i>val</i>     | The value to be set to the timer modulo |

**29.2.5.14** `static uint16_t FTM_HAL_GetMod ( FTM_Type * ftmBase ) [inline], [static]`

### Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

### Returns

FTM timer modulo value

**29.2.5.15** `static void FTM_HAL_SetCounterInitVal ( FTM_Type * ftmBase, uint16_t val ) [inline], [static]`

### Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
| <i>val</i>     | initial value to be set      |

**29.2.5.16** `static uint16_t FTM_HAL_GetCounterInitVal ( FTM_Type * ftmBase ) [inline], [static]`

### Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

### Returns

FTM timer counter initial value

**29.2.5.17** `static void FTM_HAL_SetChnMSnBAMode ( FTM_Type * ftmBase, uint8_t channel, uint8_t selection ) [inline], [static]`

Parameters

|                  |                                                           |
|------------------|-----------------------------------------------------------|
| <i>ftmBase</i>   | The FTM base address pointer                              |
| <i>channel</i>   | The FTM peripheral channel number                         |
| <i>selection</i> | The mode to be set valid value MSnB:MSnA : 00, 01, 10, 11 |

**29.2.5.18 static void FTM\_HAL\_SetChnEdgeLevel ( FTM\_Type \* *ftmBase*, uint8\_t *channel*, uint8\_t *level* ) [inline], [static]**

Parameters

|                |                                                                                |
|----------------|--------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                   |
| <i>channel</i> | The FTM peripheral channel number                                              |
| <i>level</i>   | The rising or falling edge to be set, valid value ELSnB:ELSnA : 00, 01, 10, 11 |

**29.2.5.19 static uint8\_t FTM\_HAL\_GetChnMode ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

Returns

The MSnB:MSnA mode value, will be 00, 01, 10, 11

**29.2.5.20 static uint8\_t FTM\_HAL\_GetChnEdgeLevel ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

## FlexTimer HAL driver

|                |                                   |
|----------------|-----------------------------------|
| <i>channel</i> | The FTM peripheral channel number |
|----------------|-----------------------------------|

Returns

The ELSnB:ELSnA mode value, will be 00, 01, 10, 11

**29.2.5.21** `static void FTM_HAL_SetChnDmaCmd ( FTM_Type * ftmBase, uint8_t channel, bool val ) [inline], [static]`

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |
| <i>val</i>     | enable or disable                 |

**29.2.5.22** `static bool FTM_HAL_IsChnDma ( FTM_Type * ftmBase, uint8_t channel ) [inline], [static]`

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

Returns

true if enabled, false if disabled

**29.2.5.23** `static bool FTM_HAL_IsChnIntEnabled ( FTM_Type * ftmBase, uint8_t channel ) [inline], [static]`

Parameters

|                |                          |
|----------------|--------------------------|
| <i>ftmBase</i> | FTM module base address. |
|----------------|--------------------------|

|                |                                   |
|----------------|-----------------------------------|
| <i>channel</i> | The FTM peripheral channel number |
|----------------|-----------------------------------|

Returns

true if enabled, false if disabled

**29.2.5.24 static void FTM\_HAL\_EnableChnInt ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

**29.2.5.25 static void FTM\_HAL\_DisableChnInt ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

**29.2.5.26 static bool FTM\_HAL\_HasChnEventOccurred ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

Returns

true if event occurred, false otherwise.

**29.2.5.27 static void FTM\_HAL\_ClearChnEventFlag ( FTM\_Type \* *ftmBase*, uint8\_t *channel* ) [inline], [static]**

## FlexTimer HAL driver

### Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

**29.2.5.28** `static void FTM_HAL_SetChnCountVal ( FTM_Type * ftmBase, uint8_t channel, uint16_t val ) [inline], [static]`

### Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |
| <i>val</i>     | counter value to be set           |

**29.2.5.29** `static uint16_t FTM_HAL_GetChnCountVal ( FTM_Type * ftmBase, uint8_t channel ) [inline], [static]`

### Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

### Returns

return channel counter value

**29.2.5.30** `static uint32_t FTM_HAL_GetChnEventStatus ( FTM_Type * ftmBase, uint8_t channel ) [inline], [static]`

### Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

Returns

return channel event status value

**29.2.5.31** `static void FTM_HAL_ClearChnEventStatus ( FTM_Type * ftmBase, uint8_t channel ) [inline], [static]`

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |

**29.2.5.32** `static void FTM_HAL_SetOutmaskReg ( FTM_Type * ftmBase, uint32_t regVal ) [inline], [static]`

This function will mask/uumask multiple channels.

Parameters

|                |                                     |
|----------------|-------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer        |
| <i>regVal</i>  | value to be written to the register |

**29.2.5.33** `static void FTM_HAL_SetChnOutputMask ( FTM_Type * ftmBase, uint8_t channel, bool mask ) [inline], [static]`

Parameters

|                |                                           |
|----------------|-------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer              |
| <i>channel</i> | The FTM peripheral channel number         |
| <i>mask</i>    | mask to be set 0 or 1, unmasked or masked |

**29.2.5.34** `static void FTM_HAL_SetChnOutputInitStateCmd ( FTM_Type * ftmBase, uint8_t channel, uint8_t state ) [inline], [static]`

## FlexTimer HAL driver

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |
| <i>state</i>   | counter value to be set 0 or 1    |

**29.2.5.35** `static void FTM_HAL_SetChnOutputPolarityCmd ( FTM_Type * ftmBase,  
uint8_t channel, uint8_t pol ) [inline], [static]`

Parameters

|                |                                   |
|----------------|-----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer      |
| <i>channel</i> | The FTM peripheral channel number |
| <i>pol</i>     | polarity to be set 0 or 1         |

**29.2.5.36** `static void FTM_HAL_SetChnFaultInputPolarityCmd ( FTM_Type * ftmBase,  
uint8_t channel, uint8_t pol ) [inline], [static]`

Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                     |
| <i>channel</i> | The FTM peripheral channel number                |
| <i>pol</i>     | polarity to be set, 0: active high, 1:active low |

**29.2.5.37** `static void FTM_HAL_EnableFaultInt ( FTM_Type * ftmBase ) [inline],  
[static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.38** `static void FTM_HAL_DisableFaultInt ( FTM_Type * ftmBase ) [inline],  
[static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.39** `static void FTM_HAL_SetFaultControlMode ( FTM_Type * ftmBase, uint8_t mode ) [inline], [static]`

Parameters

|                    |                              |
|--------------------|------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer |
| <i>mode, valid</i> | options are 1, 2, 3, 4       |

**29.2.5.40** `static void FTM_HAL_SetCaptureTestCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                       |
| <i>enable</i>  | true to enable capture test mode, false to disable |

**29.2.5.41** `static void FTM_HAL_SetWriteProtectionCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                        |
|----------------|------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                           |
| <i>enable</i>  | true: Write-protection is enabled, false: Write-protection is disabled |

**29.2.5.42** `static void FTM_HAL_Enable ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

---

## FlexTimer HAL driver

|                |                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                 |
| <i>enable</i>  | true: all registers including FTM-specific registers are available<br>false: only the TPM-compatible registers are available |

**29.2.5.43** `static void FTM_HAL_SetInitChnOutputCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                           |
| <i>enable</i>  | true: the channels output is initialized according to the state of OUTINIT reg<br>false: has no effect |

**29.2.5.44** `static void FTM_HAL_SetPwmSyncMode ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                                                                                     |
| <i>enable</i>  | true: no restriction both software and hardware triggers can be used<br>false: software trigger can only be used for MOD and CnV synch, hardware trigger only for OUTMASK and FTM counter synch. |

**29.2.5.45** `static void FTM_HAL_SetSoftwareTriggerCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                             |
|----------------|-----------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer.                                               |
| <i>enable</i>  | true: software trigger is selected, false: software trigger is not selected |

**29.2.5.46** `void FTM_HAL_SetHardwareSyncTriggerSrc ( FTM_Type * ftmBase, uint32_t trigger_num, bool enable )`

Parameters

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                                                                                                               |
| <i>trigger_num</i> | 0, 1, 2 for trigger0, trigger1, and trigger3                                                                                               |
| <i>enable</i>      | true: enable hardware trigger from field trigger_num for PWM synch<br>false: disable hardware trigger from field trigger_num for PWM synch |

**29.2.5.47** `static void FTM_HAL_SetOutmaskPwmSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                         |
| <i>enable</i>  | true if OUTMASK register is updated only by PWM sync<br>false if OUTMASK register is updated in all rising edges of the system clock |

**29.2.5.48** `static void FTM_HAL_SetCountReinitSyncCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                        |
| <i>enable</i>  | True to update FTM counter when triggered , false to count normally |

**29.2.5.49** `static void FTM_HAL_SetMaxLoadingCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                           |
| <i>enable</i>  | True to enable maximum loading point, false to disable |

**29.2.5.50** `static void FTM_HAL_SetMinLoadingCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

## FlexTimer HAL driver

Parameters

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                           |
| <i>enable</i>  | True to enable minimum loading point, false to disable |

### 29.2.5.51 `uint32_t FTM_HAL_GetChnPairIndex ( uint8_t channel )`

Returns an index for each channel pair.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>channel</i> | The FTM peripheral channel number. |
|----------------|------------------------------------|

Returns

- 0 for channel pair 0 & 1
- 1 for channel pair 2 & 3
- 2 for channel pair 4 & 5
- 3 for channel pair 6 & 7

### 29.2.5.52 `static void FTM_HAL_SetDualChnFaultCmd ( FTM_Type * ftmBase, uint8_t chnPairNum, bool enable ) [inline], [static]`

Parameters

|                   |                                                |
|-------------------|------------------------------------------------|
| <i>ftmBase</i>    | The FTM base address pointer                   |
| <i>chnPairNum</i> | The FTM peripheral channel pair number         |
| <i>enable</i>     | True to enable fault control, false to disable |

### 29.2.5.53 `static void FTM_HAL_SetDualChnPwmSyncCmd ( FTM_Type * ftmBase, uint8_t chnPairNum, bool enable ) [inline], [static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

|                    |                                                      |
|--------------------|------------------------------------------------------|
| <i>chnlPairNum</i> | The FTM peripheral channel pair number               |
| <i>enable</i>      | True to enable PWM synchronization, false to disable |

**29.2.5.54** `static void FTM_HAL_SetDualChnDeadtimeCmd ( FTM_Type * ftmBase, uint8_t chnlPairNum, bool enable ) [inline], [static]`

Parameters

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                        |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number              |
| <i>enable</i>      | True to enable deadtime insertion, false to disable |

**29.2.5.55** `static void FTM_HAL_SetDualChnDecapCmd ( FTM_Type * ftmBase, uint8_t chnlPairNum, bool enable ) [inline], [static]`

Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                            |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number                  |
| <i>enable</i>      | True to enable dual edge capture mode, false to disable |

**29.2.5.56** `static void FTM_HAL_SetDualEdgeCaptureCmd ( FTM_Type * ftmBase, uint8_t chnlPairNum, bool enable ) [inline], [static]`

Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                       |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number             |
| <i>enable</i>      | True to enable dual edge capture, false to disable |

**29.2.5.57** `static void FTM_HAL_SetDualChnCompCmd ( FTM_Type * ftmBase, uint8_t chnlPairNum, bool enable ) [inline], [static]`

## FlexTimer HAL driver

### Parameters

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                        |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number              |
| <i>enable</i>      | True to enable complementary mode, false to disable |

**29.2.5.58** `static void FTM_HAL_SetDualChnCombineCmd ( FTM_Type * ftmBase, uint8_t chnlPairNum, bool enable ) [inline], [static]`

### Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                             |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number                   |
| <i>enable</i>      | True to enable channel pair to combine, false to disable |

**29.2.5.59** `static void FTM_HAL_SetDeadtimePrescale ( FTM_Type * ftmBase, ftm_deadtime_ps_t divider ) [inline], [static]`

### Parameters

|                |                                                                                             |
|----------------|---------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                |
| <i>divider</i> | The FTM peripheral prescale divider<br>0x :divided by 1, 10: divided by 4, 11:divided by 16 |

**29.2.5.60** `static void FTM_HAL_SetDeadtimeCount ( FTM_Type * ftmBase, uint8_t count ) [inline], [static]`

### Parameters

|                |                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                     |
| <i>count</i>   | The FTM peripheral prescale divider<br>0: no counts inserted, 1: 1 count is inserted, 2: 2 count is inserted.... |

**29.2.5.61 static void FTM\_HAL\_SetInitTriggerCmd ( FTM\_Type \* *ftmBase*, bool *enable* )**  
**[inline], [static]**

Parameters

|                |                                  |
|----------------|----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer     |
| <i>enable</i>  | True to enable, false to disable |

**29.2.5.62 void FTM\_HAL\_SetChnTriggerCmd ( FTM\_Type \* *ftmBase*, uint8\_t *channel*, bool *val* )**

Enables or disables the generation of the FTM peripheral timer channel trigger when the FTM counter is equal to its initial value. Channels 6 and 7 cannot be used as triggers.

Parameters

|                |                                                     |
|----------------|-----------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                        |
| <i>channel</i> | Channel to be enabled, valid value 0, 1, 2, 3, 4, 5 |
| <i>val</i>     | True to enable, false to disable                    |

**29.2.5.63 static bool FTM\_HAL\_IsChnTriggerGenerated ( FTM\_Type \* *ftmBase* )**  
**[inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

true if there is a channel trigger event, false if not.

**29.2.5.64 static uint8\_t FTM\_HAL\_GetDetectedFaultInput ( FTM\_Type \* *ftmBase* )**  
**[inline], [static]**

This function reads the status for all fault inputs

## FlexTimer HAL driver

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

Return fault byte

**29.2.5.65 static bool FTM\_HAL\_IsWriteProtectionEnabled ( FTM\_Type \* *ftmBase* )  
[inline], [static]**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

True if enabled, false if not

**29.2.5.66 static void FTM\_HAL\_SetQuadDecoderCmd ( FTM\_Type \* *ftmBase*, bool  
*enable* ) [inline], [static]**

Parameters

|                |                                  |
|----------------|----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer     |
| <i>enable</i>  | True to enable, false to disable |

**29.2.5.67 static void FTM\_HAL\_SetQuadPhaseAFilterCmd ( FTM\_Type \* *ftmBase*, bool  
*enable* ) [inline], [static]**

Parameters

|                |                                                                |
|----------------|----------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                   |
| <i>enable</i>  | true enables the phase input filter, false disables the filter |

**29.2.5.68** `static void FTM_HAL_SetQuadPhaseBFilterCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                |
|----------------|----------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                   |
| <i>enable</i>  | true enables the phase input filter, false disables the filter |

**29.2.5.69** `static void FTM_HAL_SetQuadPhaseAPolarity ( FTM_Type * ftmBase, ftm_quad_phase_polarity_t mode ) [inline], [static]`

Parameters

|                |                                          |
|----------------|------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer             |
| <i>mode</i>    | 0: Normal polarity, 1: Inverted polarity |

**29.2.5.70** `static void FTM_HAL_SetQuadPhaseBPolarity ( FTM_Type * ftmBase, ftm_quad_phase_polarity_t mode ) [inline], [static]`

Parameters

|                |                                          |
|----------------|------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer             |
| <i>mode</i>    | 0: Normal polarity, 1: Inverted polarity |

**29.2.5.71** `static void FTM_HAL_SetQuadMode ( FTM_Type * ftmBase, ftm_quad_decode_mode_t quadMode ) [inline], [static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

## FlexTimer HAL driver

|                 |                                                                              |
|-----------------|------------------------------------------------------------------------------|
| <i>quadMode</i> | 0: Phase A and Phase B encoding mode<br>1: Count and direction encoding mode |
|-----------------|------------------------------------------------------------------------------|

**29.2.5.72** `static uint8_t FTM_HAL_GetQuadDir ( FTM_Type * ftmBase ) [inline], [static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

1 if counting direction is increasing, 0 if counting direction is decreasing

**29.2.5.73** `static uint8_t FTM_HAL_GetQuadTimerOverflowDir ( FTM_Type * ftmBase ) [inline], [static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

Returns

1 if TOF bit was set on the top of counting, 0 if TOF bit was set on the bottom of counting

**29.2.5.74** `void FTM_HAL_SetChnInputCaptureFilter ( FTM_Type * ftmBase, uint8_t channel, uint8_t val )`

Parameters

|                |                                                                                    |
|----------------|------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                       |
| <i>channel</i> | The FTM peripheral channel number, only 0, 1, 2, 3, channel 4, 5, 6, 7 don't have. |
| <i>val</i>     | Filter value to be set                                                             |

**29.2.5.75** `static void FTM_HAL_SetFaultInputFilterVal ( FTM_Type * ftmBase, uint32_t val ) [inline], [static]`

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
| <i>val</i>     | fault input filter value     |

**29.2.5.76** `static void FTM_HAL_SetFaultInputFilterCmd ( FTM_Type * ftmBase, uint8_t inputNum, bool val ) [inline], [static]`

Parameters

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <i>ftmBase</i>  | The FTM base address pointer                                           |
| <i>inputNum</i> | fault input to be configured, valid value 0, 1, 2, 3                   |
| <i>val</i>      | true to enable fault input filter, false to disable fault input filter |

**29.2.5.77** `static void FTM_HAL_SetFaultInputCmd ( FTM_Type * ftmBase, uint8_t inputNum, bool val ) [inline], [static]`

Parameters

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| <i>ftmBase</i>  | The FTM base address pointer                             |
| <i>inputNum</i> | fault input to be configured, valid value 0, 1, 2, 3     |
| <i>val</i>      | true to enable fault input, false to disable fault input |

**29.2.5.78** `static void FTM_HAL_SetDualChnInvertCmd ( FTM_Type * ftmBase, uint8_t chnIPairNum, bool val ) [inline], [static]`

Parameters

---

## FlexTimer HAL driver

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <i>ftmBase</i>     | The FTM base address pointer                                     |
| <i>chnlPairNum</i> | The FTM peripheral channel pair number                           |
| <i>val</i>         | true to enable channel inverting, false to disable channel inver |

**29.2.5.79** `static void FTM_HAL_SetInvctrlReg ( FTM_Type * ftmBase, uint32_t regVal ) [inline], [static]`

This function is enable/disable inverting control on multiple channel pairs.

Parameters

|                |                                     |
|----------------|-------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer        |
| <i>regVal</i>  | value to be written to the register |

**29.2.5.80** `static void FTM_HAL_SetChnSoftwareCtrlCmd ( FTM_Type * ftmBase, uint8_t channel, bool val ) [inline], [static]`

Parameters

|                |                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                 |
| <i>channel</i> | Channel to be enabled or disabled                                                                                            |
| <i>val</i>     | true to enable, channel output will be affected by software output control<br>false to disable, channel output is unaffected |

**29.2.5.81** `static void FTM_HAL_SetChnSoftwareCtrlVal ( FTM_Type * ftmBase, uint8_t channel, bool val ) [inline], [static]`

Parameters

|                |                               |
|----------------|-------------------------------|
| <i>ftmBase</i> | The FTM base address pointer. |
| <i>channel</i> | Channel to be configured      |
| <i>val</i>     | True to set 1, false to set 0 |

**29.2.5.82** `static void FTM_HAL_SetPwmLoadCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                  |
|----------------|----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer     |
| <i>enable</i>  | true to enable, false to disable |

**29.2.5.83** `static void FTM_HAL_SetPwmLoadChnSelCmd ( FTM_Type * ftmBase, uint8_t channel, bool val ) [inline], [static]`

Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>channel</i> | Channel to be configured                                                                                             |
| <i>val</i>     | true means include the channel in the matching process<br>false means do not include channel in the matching process |

**29.2.5.84** `static void FTM_HAL_SetGlobalTimeBaseOutputCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                  |
|----------------|----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer     |
| <i>enable</i>  | True to enable, false to disable |

**29.2.5.85** `static void FTM_HAL_SetGlobalTimeBaseCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

---

## FlexTimer HAL driver

|                |                                  |
|----------------|----------------------------------|
| <i>ftmBase</i> | The FTM base address pointer     |
| <i>enable</i>  | True to enable, false to disable |

**29.2.5.86** `static void FTM_HAL_SetBdmMode ( FTM_Type * ftmBase, ftm_bdm_mode_t val ) [inline], [static]`

Parameters

|                |                                                                                        |
|----------------|----------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                           |
| <i>val</i>     | FTM behaviour in BDM mode, options are defined in the enum <code>ftm_bdm_mode_t</code> |

**29.2.5.87** `static void FTM_HAL_SetTofFreq ( FTM_Type * ftmBase, uint8_t val ) [inline], [static]`

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer       |
| <i>val</i>     | Value of the TOF bit set frequency |

**29.2.5.88** `void FTM_HAL_SetSyncMode ( FTM_Type * ftmBase, uint32_t syncMethod )`

This function will set the necessary bits for the synchronization mode that user wishes to use.

Parameters

|                   |                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i>    | The FTM base address pointer                                                                                                    |
| <i>syncMethod</i> | Synchronization method defined by <code>ftm_sync_method_t</code> enum. User can choose multiple synch methods by OR'ing options |

**29.2.5.89** `static void FTM_HAL_SetSwoctrlHardwareSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                 |
| <i>enable</i>  | true means the hardware trigger activates register sync<br>false means the hardware trigger does not activate register sync. |

**29.2.5.90** `static void FTM_HAL_SetInvctrlHardwareSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                 |
| <i>enable</i>  | true means the hardware trigger activates register sync<br>false means the hardware trigger does not activate register sync. |

**29.2.5.91** `static void FTM_HAL_SetOutmaskHardwareSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means hardware trigger activates register sync<br>false means hardware trigger does not activate register sync. |

**29.2.5.92** `static void FTM_HAL_SetModCntrCvHardwareSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means hardware trigger activates register sync<br>false means hardware trigger does not activate register sync. |

**29.2.5.93** `static void FTM_HAL_SetCounterHardwareSyncModeCmd ( FTM_Type * ftmBase, bool enable ) [inline], [static]`

## FlexTimer HAL driver

### Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means hardware trigger activates register sync<br>false means hardware trigger does not activate register sync. |

### 29.2.5.94 static void FTM\_HAL\_SetSwoctrlSoftwareSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]

### Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means software trigger activates register sync<br>false means software trigger does not activate register sync. |

### 29.2.5.95 static void FTM\_HAL\_SetInvctrlSoftwareSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]

### Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means software trigger activates register sync<br>false means software trigger does not activate register sync. |

### 29.2.5.96 static void FTM\_HAL\_SetOutmaskSoftwareSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]

### Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means software trigger activates register sync<br>false means software trigger does not activate register sync. |

**29.2.5.97 static void FTM\_HAL\_SetModCntrnCvSoftwareSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means software trigger activates register sync<br>false means software trigger does not activate register sync. |

**29.2.5.98 static void FTM\_HAL\_SetCounterSoftwareSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                         |
| <i>enable</i>  | true means software trigger activates register sync<br>false means software trigger does not activate register sync. |

**29.2.5.99 static void FTM\_HAL\_SetPwmSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

|                |                                                                               |
|----------------|-------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                  |
| <i>enable</i>  | true means use Enhanced PWM synchronization<br>false means to use Legacy mode |

**29.2.5.100 static void FTM\_HAL\_SetSwoctrIPwmSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

## FlexTimer HAL driver

|                |                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                       |
| <i>enable</i>  | true means SWOCTRL register is updated by PWM synch<br>false means SWOCTRL register is updated at all rising edges of system clock |

**29.2.5.101 static void FTM\_HAL\_SetInvctrlPwmSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

|                |                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                       |
| <i>enable</i>  | true means INVCTRL register is updated by PWM synch<br>false means INVCTRL register is updated at all rising edges of system clock |

**29.2.5.102 static void FTM\_HAL\_SetCntinPwmSyncModeCmd ( FTM\_Type \* *ftmBase*, bool *enable* ) [inline], [static]**

Parameters

|                |                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                                                                                                   |
| <i>enable</i>  | true means CNTIN register is updated by PWM synch<br>false means CNTIN register is updated at all rising edges of system clock |

**29.2.5.103 void FTM\_HAL\_Reset ( FTM\_Type \* *ftmBase* )**

Parameters

|                |                              |
|----------------|------------------------------|
| <i>ftmBase</i> | The FTM base address pointer |
|----------------|------------------------------|

**29.2.5.104 void FTM\_HAL\_Init ( FTM\_Type \* *ftmBase* )**

Parameters

---

|                |                               |
|----------------|-------------------------------|
| <i>ftmBase</i> | The FTM base address pointer. |
|----------------|-------------------------------|

**29.2.5.105** void FTM\_HAL\_EnablePwmMode ( FTM\_Type \* *ftmBase*, ftm\_pwm\_param\_t \* *config*, uint8\_t *channel* )

Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                       |
| <i>config</i>  | PWM configuration parameter                        |
| <i>channel</i> | The channel or channel pair number(combined mode). |

**29.2.5.106** void FTM\_HAL\_DisablePwmMode ( FTM\_Type \* *ftmBase*, ftm\_pwm\_param\_t \* *config*, uint8\_t *channel* )

Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>ftmBase</i> | The FTM base address pointer                       |
| <i>config</i>  | PWM configuration parameter                        |
| <i>channel</i> | The channel or channel pair number(combined mode). |

## FlexTimer Peripheral Driver

### 29.3 FlexTimer Peripheral Driver

#### 29.3.1 Overview

This section describes the programming interface of the FlexTimer Peripheral driver.

#### 29.3.2 FlexTimer Overview

The FlexTimer module is a timer that supports input capture, output compare, and generation of PWM signals. The current Kinetis SDK driver only supports the generation of PWM signals. The input capture and output compare will be supported in upcoming Kinetis SDK releases.

#### 29.3.3 FlexTimer Initialization

1. To initialize the FlexTimer driver, call the [FTM\\_DRV\\_Init\(\)](#) function and pass the instance number of the relevant FTM. For example, to use FTM0, pass a value of 0 to the initialization function.
2. Pass a user configuration structure [ftm\\_user\\_config\\_t](#), as shown here:

```
// FTM configuration structure
typedef struct FtmUserConfig {
 uint8_t tofFrequency;
 bool isFTMMode;
 uint8_t BDMMode;
 bool isWriteProtection;

 bool isTimerOverFlowInterrupt;
 bool isFaultInterrupt;
} ftm_user_config_t;
```

#### 29.3.4 FlexTimer Generate a PWM signal

FTM calls the [FTM\\_DRV\\_PwmStart\(\)](#) function to generate a PWM signal. Use this structure to configure different parameters for the PWM signal.

```
typedef struct FtmPwmParam
{
 ftm_config_mode_t mode;
 ftm_pwm_edge_mode_t edgeMode;
 uint32_t uFrequencyHZ;
 uint32_t uDutyCyclePercent;

 uint16_t uFirstEdgeDelayPercent;
} ftm_pwm_param_t;
```

0 = inactive signal (0% duty cycle)...  
100 = active signal (100% duty cycle). //

Specifies the delay to the first edge in a PWM period.  
If unsure leave as 0. Should be specified as  
percentage of the PWM period//

The mode options are `kFtmEdgeAlignedPWM`, `kFtmCenterAlignedPWM`, and `kFtmCombinedPWM`. For edge mode, the options available are `kFtmHighTrue` and `kFtmLowTrue`. Specify the PWM signal frequency in Hz and the duty cycle percentage (value between 0-100). If the PWM mode is `kFtmCombinedPWM` and if the user chooses to specify a value for the `uFirstEdgeDelayPercent`, start of the PWM pulse is delayed.

### Data Structures

- struct `ftm_user_config_t`  
Configuration structure that the user needs to set. *More...*

### Functions

- `ftm_status_t FTM_DRV_Init` (uint32\_t instance, const `ftm_user_config_t` \*info)  
*Initializes the FTM driver.*
- void `FTM_DRV_Deinit` (uint32\_t instance)  
*Shuts down the FTM driver.*
- void `FTM_DRV_PwmStop` (uint32\_t instance, `ftm_pwm_param_t` \*param, uint8\_t channel)  
*Stops the channel PWM.*
- `ftm_status_t FTM_DRV_PwmStart` (uint32\_t instance, `ftm_pwm_param_t` \*param, uint8\_t channel)  
*Configures the duty cycle and frequency and starts outputting the PWM on a specified channel.*
- void `FTM_DRV_QuadDecodeStart` (uint32\_t instance, `ftm_phase_params_t` \*phaseAParams, `ftm_phase_params_t` \*phaseBParams, `ftm_quad_decode_mode_t` quadMode)  
*Configures the parameters and activates the quadrature decode mode.*
- void `FTM_DRV_QuadDecodeStop` (uint32\_t instance)  
*Deactivates the quadrature decode mode.*
- void `FTM_DRV_CounterStart` (uint32\_t instance, `ftm_counting_mode_t` countMode, uint32\_t countStartVal, uint32\_t countFinalVal, bool enableOverflowInt)  
*Starts the FTM counter.*
- void `FTM_DRV_CounterStop` (uint32\_t instance)  
*Stops the FTM counter.*
- uint32\_t `FTM_DRV_CounterRead` (uint32\_t instance)  
*Reads back the current value of the FTM counter.*
- void `FTM_DRV_SetClock` (uint8\_t instance, `ftm_clock_source_t` clock, `ftm_clock_ps_t` clockPs)  
*Sets the FTM clock source.*
- uint32\_t `FTM_DRV_GetClock` (uint8\_t instance)  
*Retrieves the frequency of the clock source feeding the FTM counter.*
- void `FTM_DRV_SetTimeOverflowIntCmd` (uint32\_t instance, bool overflowEnable)  
*Enables or disables the timer overflow interrupt.*
- void `FTM_DRV_SetFaultIntCmd` (uint32\_t instance, bool faultEnable)  
*Enables or disables the fault interrupt.*
- void `FTM_DRV_SetupChnInputCapture` (uint32\_t instance, `ftm_input_capture_edge_mode_t` captureMode, uint8\_t channel, uint8\_t filterVal)  
*Enables capturing an input signal on the channel using the function parameters.*
- void `FTM_DRV_SetupChnOutputCompare` (uint32\_t instance, `ftm_output_compare_edge_mode_t` compareMode, uint8\_t channel, uint32\_t compareVal)

## FlexTimer Peripheral Driver

- Configures the FTM to generate timed pulses.*

• void [FTM\\_DRV\\_SetupChnDualEdgeCapture](#) (uint32\_t instance, [ftm\\_dual\\_edge\\_capture\\_param\\_t](#) \*param, uint8\_t channel, uint8\_t filterVal)

*Configures the dual edge capture mode of the FTM.*
- void [FTM\\_DRV\\_IRQHandler](#) (uint32\_t instance)

*Action to take when an FTM interrupt is triggered.*

### Variables

- FTM\_Type \*const [g\\_ftmBase](#) [FTM\_INSTANCE\_COUNT]

*Table of base addresses for FTM instances.*
- const IRQn\_Type [g\\_ftmIrqId](#) [FTM\_INSTANCE\_COUNT]

*Table to save FTM IRQ enumeration numbers defined in the CMSIS header file.*

## 29.3.5 Data Structure Documentation

### 29.3.5.1 struct ftm\_user\_config\_t

#### Data Fields

- uint8\_t [tofFrequency](#)

*Select ratio between number of overflows to times TOF is set.*
- [ftm\\_bdm\\_mode\\_t](#) [BDMMode](#)

*Select FTM behavior in BDM mode.*
- bool [isWriteProtection](#)

*true: enable write protection, false: write protection is disabled*
- uint32\_t [syncMethod](#)

*Register synch options available in the [ftm\\_sync\\_method\\_t](#) enumeration.*

## 29.3.6 Function Documentation

### 29.3.6.1 [ftm\\_status\\_t](#) [FTM\\_DRV\\_Init](#) ( uint32\_t *instance*, const [ftm\\_user\\_config\\_t](#) \* *info* )

#### Parameters

|                 |                                                                               |
|-----------------|-------------------------------------------------------------------------------|
| <i>instance</i> | The FTM peripheral instance number.                                           |
| <i>info</i>     | The FTM user configuration structure, see <a href="#">ftm_user_config_t</a> . |

#### Returns

[kStatusFtmSuccess](#) means success. Otherwise means failure.

### 29.3.6.2 void [FTM\\_DRV\\_Deinit](#) ( uint32\_t *instance* )

Parameters

|                 |                                     |
|-----------------|-------------------------------------|
| <i>instance</i> | The FTM peripheral instance number. |
|-----------------|-------------------------------------|

**29.3.6.3 void FTM\_DRV\_PwmStop ( uint32\_t *instance*, ftm\_pwm\_param\_t \* *param*, uint8\_t *channel* )**

Parameters

|                 |                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------|
| <i>instance</i> | The FTM peripheral instance number.                                                                                 |
| <i>param</i>    | FTM driver PWM parameter to configure PWM options                                                                   |
| <i>channel</i>  | The channel number. In combined mode, the code finds the channel pair associated with the channel number passed in. |

**29.3.6.4 ftm\_status\_t FTM\_DRV\_PwmStart ( uint32\_t *instance*, ftm\_pwm\_param\_t \* *param*, uint8\_t *channel* )**

Parameters

|                 |                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------|
| <i>instance</i> | The FTM peripheral instance number.                                                                                 |
| <i>param</i>    | FTM driver PWM parameter to configure PWM options                                                                   |
| <i>channel</i>  | The channel number. In combined mode, the code finds the channel pair associated with the channel number passed in. |

Returns

kStatusFtmSuccess if the PWM setup was successful, kStatusFtmError on failure as the PWM counter is disabled

**29.3.6.5 void FTM\_DRV\_QuadDecodeStart ( uint32\_t *instance*, ftm\_phase\_params\_t \* *phaseAParams*, ftm\_phase\_params\_t \* *phaseBParams*, ftm\_quad\_decode\_mode\_t *quadMode* )**

Parameters

---

## FlexTimer Peripheral Driver

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| <i>instance</i>     | Instance number of the FTM module.                    |
| <i>phaseAParams</i> | Phase A configuration parameters                      |
| <i>phaseBParams</i> | Phase B configuration parameters                      |
| <i>quadMode</i>     | Selects encoding mode used in quadrature decoder mode |

### 29.3.6.6 void FTM\_DRV\_QuadDecodeStop ( uint32\_t instance )

Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the FTM module. |
|-----------------|------------------------------------|

### 29.3.6.7 void FTM\_DRV\_CounterStart ( uint32\_t instance, ftm\_counting\_mode\_t countMode, uint32\_t countStartVal, uint32\_t countFinalVal, bool enableOverflowInt )

This function provides access to the FTM counter. The counter can be run in up-counting and up-down counting modes. To run the counter in free running mode, choose the up-counting option and provide 0x0 for the countStartVal and 0xFFFF for countFinalVal.

Parameters

|                           |                                                          |
|---------------------------|----------------------------------------------------------|
| <i>instance</i>           | The FTM peripheral instance number.                      |
| <i>countMode</i>          | The FTM counter mode defined by ftm_counting_mode_t.     |
| <i>countStartVal</i>      | The starting value that is stored in the CNTIN register. |
| <i>countFinalVal</i>      | The final value that is stored in the MOD register.      |
| <i>enable-OverflowInt</i> | true: enable timer overflow interrupt; false: disable    |

### 29.3.6.8 void FTM\_DRV\_CounterStop ( uint32\_t instance )

Parameters

|                 |                                     |
|-----------------|-------------------------------------|
| <i>instance</i> | The FTM peripheral instance number. |
|-----------------|-------------------------------------|

### 29.3.6.9 uint32\_t FTM\_DRV\_CounterRead ( uint32\_t *instance* )

Parameters

|                 |                                     |
|-----------------|-------------------------------------|
| <i>instance</i> | The FTM peripheral instance number. |
|-----------------|-------------------------------------|

Returns

The counter value.

### 29.3.6.10 void FTM\_DRV\_SetClock ( uint8\_t *instance*, ftm\_clock\_source\_t *clock*, ftm\_clock\_ps\_t *clockPs* )

This function saves the user's clock source selection in the driver to set the clock source and use features provided by the driver-like counter, PWM generation, and so on. This function also sets the clock divider.

Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The FTM peripheral instance number.        |
| <i>clock</i>    | The clock source to use, cannot pick None. |
| <i>clockPs</i>  | The clock divider value.                   |

### 29.3.6.11 uint32\_t FTM\_DRV\_GetClock ( uint8\_t *instance* )

This function returns zero if no clock source is selected and the FTM counter is disabled.

Parameters

|                 |                                     |
|-----------------|-------------------------------------|
| <i>instance</i> | The FTM peripheral instance number. |
|-----------------|-------------------------------------|

Returns

The frequency of the clock source running the FTM counter, returns 0 if counter is disabled

### 29.3.6.12 void FTM\_DRV\_SetTimeOverflowIntCmd ( uint32\_t *instance*, bool *overflowEnable* )

## FlexTimer Peripheral Driver

### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <i>instance</i>       | The FTM peripheral instance number.                       |
| <i>overflowEnable</i> | true: enable the timer overflow interrupt, false: disable |

### 29.3.6.13 void FTM\_DRV\_SetFaultIntCmd ( uint32\_t instance, bool faultEnable )

### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>instance</i>    | The FTM peripheral instance number.              |
| <i>faultEnable</i> | true: enable the fault interrupt, false: disable |

### 29.3.6.14 void FTM\_DRV\_SetupChnInputCapture ( uint32\_t instance, ftm\_input\_capture\_edge\_mode\_t captureMode, uint8\_t channel, uint8\_t filterVal )

When the edge specified in the captureMode argument occurs on the channel, the FTM counter is captured into the CnV register. The user has to read the CnV register separately to get this value. The filter function is disabled if the filterVal argument passed in is 0. The filter function is available only for 0, 1, 2, 3 channels.

### Parameters

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <i>instance</i>    | The FTM peripheral instance number                                                    |
| <i>captureMode</i> | Specifies which edge to capture                                                       |
| <i>channel</i>     | The channel number                                                                    |
| <i>filterVal</i>   | Filter value to be used, specify 0 to disable filter. Available only for channels 0-3 |

### 29.3.6.15 void FTM\_DRV\_SetupChnOutputCompare ( uint32\_t instance, ftm\_output\_compare\_edge\_mode\_t compareMode, uint8\_t channel, uint32\_t compareVal )

When the FTM counter matches the value of compareVal argument (this is written into CnV reg), the channel output is changed based on what is specified in the compareMode argument.

## Parameters

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <i>instance</i>    | The FTM peripheral instance number.                                    |
| <i>compareMode</i> | Action to take on the channel output when the compare condition is met |
| <i>channel</i>     | The channel number                                                     |
| <i>compareVal</i>  | Value to be programmed in the CnV register.                            |

**29.3.6.16 void FTM\_DRV\_SetupChnDualEdgeCapture ( uint32\_t instance, ftm\_dual\_edge\_capture\_param\_t \* param, uint8\_t channel, uint8\_t filterVal )**

This function sets up the dual edge capture mode on a channel pair. The capture edge for the channel pair and the capture mode (one-shot or continuous) is specified in the parameter argument. The filter function is disabled if the filterVal argument passed is zero. The filter function is available only on channels 0 and 2. The user has to read the channel CnV registers separately to get the capture values.

## Parameters

|                  |                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------|
| <i>instance</i>  | The FTM peripheral instance number.                                                               |
| <i>param</i>     | Controls the dual edge capture function                                                           |
| <i>channel</i>   | The channel number, the code finds the channel pair associated with the channel number passed in. |
| <i>filterVal</i> | Filter value to be used, specify 0 to disable filter. Available only for channels 0, 2            |

**29.3.6.17 void FTM\_DRV\_IRQHandler ( uint32\_t instance )**

The timer overflow flag is checked and cleared if set.

## Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the FTM module. |
|-----------------|------------------------------------|

## Chapter 30

# General Purpose Input/Output (GPIO)

### 30.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the General Purpose Input/Output (GPIO) block of Kinetis devices.

#### Modules

- [GPIO HAL driver](#)
- [GPIO Peripheral driver](#)

## GPIO HAL driver

### 30.2 GPIO HAL driver

#### 30.2.1 Overview

This section describes the programming interface of the GPIO HAL driver.

#### Files

- file [fsl\\_gpio\\_hal.h](#)  
*GPIO hardware driver configuration.*

#### Enumerations

- enum [gpio\\_pin\\_direction\\_t](#) {  
  [kGpioDigitalInput](#) = 0U,  
  [kGpioDigitalOutput](#) = 1U }  
*GPIO direction definition.*

#### Configuration

- void [GPIO\\_HAL\\_SetPinDir](#) (GPIO\_Type \*base, uint32\_t pin, [gpio\\_pin\\_direction\\_t](#) direction)  
*Sets the individual GPIO pin to general input or output.*
- static void [GPIO\\_HAL\\_SetPortDir](#) (GPIO\_Type \*base, uint32\_t pinDirectionMap)  
*Sets the GPIO port pins to general input or output.*

#### Status

- static [gpio\\_pin\\_direction\\_t](#) [GPIO\\_HAL\\_GetPinDir](#) (GPIO\_Type \*base, uint32\_t pin)  
*Gets the current direction of the individual GPIO pin.*
- static uint32\_t [GPIO\\_HAL\\_GetPortDir](#) (GPIO\_Type \*base)  
*Gets the GPIO port pins direction.*

#### Output Operation

- void [GPIO\\_HAL\\_WritePinOutput](#) (GPIO\_Type \*base, uint32\_t pin, uint32\_t output)  
*Sets the output level of the individual GPIO pin to logic 1 or 0.*
- static uint32\_t [GPIO\\_HAL\\_ReadPinOutput](#) (GPIO\_Type \*base, uint32\_t pin)  
*Reads the current pin output.*
- static void [GPIO\\_HAL\\_SetPinOutput](#) (GPIO\_Type \*base, uint32\_t pin)  
*Sets the output level of the individual GPIO pin to logic 1.*
- static void [GPIO\\_HAL\\_ClearPinOutput](#) (GPIO\_Type \*base, uint32\_t pin)  
*Clears the output level of the individual GPIO pin to logic 0.*
- static void [GPIO\\_HAL\\_TogglePinOutput](#) (GPIO\_Type \*base, uint32\_t pin)  
*Reverses the current output logic of the individual GPIO pin.*

- static void **GPIO\_HAL\_WritePortOutput** (GPIO\_Type \*base, uint32\_t portOutput)  
*Sets the output of the GPIO port pins to a specific logic value.*
- static uint32\_t **GPIO\_HAL\_ReadPortOutput** (GPIO\_Type \*base)  
*Reads out all pin output status of the current port.*
- static void **GPIO\_HAL\_SetPortOutput** (GPIO\_Type \*base, uint32\_t portOutput)  
*Sets the output level of the GPIO port pins to logic 1.*
- static void **GPIO\_HAL\_ClearPortOutput** (GPIO\_Type \*base, uint32\_t portOutput)  
*Clears the output level of the GPIO port pins to logic 0.*
- static void **GPIO\_HAL\_TogglePortOutput** (GPIO\_Type \*base, uint32\_t portOutput)  
*Reverses the current output logic of the GPIO port pins.*

## Input Operation

- static uint32\_t **GPIO\_HAL\_ReadPinInput** (GPIO\_Type \*base, uint32\_t pin)  
*Reads the current input value of the individual GPIO pin.*
- static uint32\_t **GPIO\_HAL\_ReadPortInput** (GPIO\_Type \*base)  
*Reads the current input value of a specific GPIO port.*

## 30.2.2 Enumeration Type Documentation

### 30.2.2.1 enum gpio\_pin\_direction\_t

Enumerator

- kGpioDigitalInput*** Set current pin as digital input.
- kGpioDigitalOutput*** Set current pin as digital output.

## 30.2.3 Function Documentation

### 30.2.3.1 void GPIO\_HAL\_SetPinDir ( GPIO\_Type \* *base*, uint32\_t *pin*, gpio\_pin\_direction\_t *direction* )

Parameters

|                  |                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>      | GPIO base pointer(PTA, PTB, PTC, etc.)                                                                                                           |
| <i>pin</i>       | GPIO port pin number                                                                                                                             |
| <i>direction</i> | GPIO directions <ul style="list-style-type: none"> <li>• kGpioDigitalInput: set to input</li> <li>• kGpioDigitalOutput: set to output</li> </ul> |

## GPIO HAL driver

**30.2.3.2** `static void GPIO_HAL_SetPortDir ( GPIO_Type * base, uint32_t pinDirectionMap ) [inline], [static]`

This function operates all 32 port pins.

## Parameters

|                         |                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>             | GPIO base pointer (PTA, PTB, PTC, etc.)                                                                                                                              |
| <i>pinDirection-Map</i> | GPIO directions bit map <ul style="list-style-type: none"> <li>• 0: set to input</li> <li>• 1: set to output</li> <li>• LSB: pin 0</li> <li>• MSB: pin 31</li> </ul> |

**30.2.3.3 static gpio\_pin\_direction\_t GPIO\_HAL\_GetPinDir ( GPIO\_Type \* *base*, uint32\_t *pin* ) [inline], [static]**

## Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                   |

## Returns

## GPIO directions

- kGpioDigitalInput: corresponding pin is set to input.
- kGpioDigitalOutput: corresponding pin is set to output.

**30.2.3.4 static uint32\_t GPIO\_HAL\_GetPortDir ( GPIO\_Type \* *base* ) [inline], [static]**

This function gets all 32-pin directions as a 32-bit integer.

## Parameters

|             |                                         |
|-------------|-----------------------------------------|
| <i>base</i> | GPIO base pointer (PTA, PTB, PTC, etc.) |
|-------------|-----------------------------------------|

## Returns

## GPIO directions. Each bit represents one pin. For each bit:

- 0: corresponding pin is set to input
- 1: corresponding pin is set to output
- LSB: pin 0
- MSB: pin 31

## GPIO HAL driver

30.2.3.5 void GPIO\_HAL\_WritePinOutput ( GPIO\_Type \* *base*, uint32\_t *pin*, uint32\_t *output* )

## Parameters

|               |                                        |
|---------------|----------------------------------------|
| <i>base</i>   | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>    | GPIO port pin number                   |
| <i>output</i> | pin output logic level                 |

**30.2.3.6 static uint32\_t GPIO\_HAL\_ReadPinOutput ( GPIO\_Type \* *base*, uint32\_t *pin* )  
[inline], [static]**

## Parameters

|             |                                         |
|-------------|-----------------------------------------|
| <i>base</i> | GPIO base pointer (PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                    |

## Returns

current pin output status. 0 - Low logic, 1 - High logic

**30.2.3.7 static void GPIO\_HAL\_SetPinOutput ( GPIO\_Type \* *base*, uint32\_t *pin* )  
[inline], [static]**

## Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                   |

**30.2.3.8 static void GPIO\_HAL\_ClearPinOutput ( GPIO\_Type \* *base*, uint32\_t *pin* )  
[inline], [static]**

## Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                   |

## GPIO HAL driver

**30.2.3.9 static void GPIO\_HAL\_TogglePinOutput ( GPIO\_Type \* *base*, uint32\_t *pin* ) [inline], [static]**

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                   |

**30.2.3.10 static void GPIO\_HAL\_WritePortOutput ( GPIO\_Type \* *base*, uint32\_t *portOutput* ) [inline], [static]**

This function operates all 32 port pins.

Parameters

|                   |                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>       | GPIO base pointer (PTA, PTB, PTC, etc.)                                                                                                                                                                                                           |
| <i>portOutput</i> | data to configure the GPIO output. Each bit represents one pin. For each bit: <ul style="list-style-type: none"> <li>• 0: set logic level 0 to pin</li> <li>• 1: set logic level 1 to pin</li> <li>• LSB: pin 0</li> <li>• MSB: pin 31</li> </ul> |

**30.2.3.11 static uint32\_t GPIO\_HAL\_ReadPortOutput ( GPIO\_Type \* *base* ) [inline], [static]**

This function operates all 32 port pins.

Parameters

|             |                                         |
|-------------|-----------------------------------------|
| <i>base</i> | GPIO base pointer (PTA, PTB, PTC, etc.) |
|-------------|-----------------------------------------|

Returns

current port output status. Each bit represents one pin. For each bit:

- 0: corresponding pin is outputting logic level 0
- 1: corresponding pin is outputting logic level 1
- LSB: pin 0
- MSB: pin 31

```
30.2.3.12 static void GPIO_HAL_SetPortOutput (GPIO_Type * base, uint32_t portOutput
) [inline], [static]
```

This function operates all 32 port pins.

## GPIO HAL driver

### Parameters

|                   |                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>       | GPIO base pointer(PTA, PTB, PTC, etc.)                                                                                                                                                                                                                          |
| <i>portOutput</i> | GPIO output port pin mask. Each bit represents one pin. For each bit: <ul style="list-style-type: none"> <li>• 0: pin output will not be changed.</li> <li>• 1: pin output will be set to logic level 1</li> <li>• LSB: pin 0</li> <li>• MSB: pin 31</li> </ul> |

### 30.2.3.13 `static void GPIO_HAL_ClearPortOutput ( GPIO_Type * base, uint32_t portOutput ) [inline], [static]`

This function operates all 32 port pins.

### Parameters

|                   |                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>       | GPIO base pointer(PTA, PTB, PTC, etc.)                                                                                                                                                                                                                         |
| <i>portOutput</i> | mask of GPIO output pins. Each bit represents one pin. For each bit: <ul style="list-style-type: none"> <li>• 0: pin output will not be changed.</li> <li>• 1: pin output will be set to logic level 0</li> <li>• LSB: pin 0</li> <li>• MSB: pin 31</li> </ul> |

### 30.2.3.14 `static void GPIO_HAL_TogglePortOutput ( GPIO_Type * base, uint32_t portOutput ) [inline], [static]`

This function operates all 32 port pins.

### Parameters

|                   |                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>       | GPIO base pointer(PTA, PTB, PTC, etc.)                                                                                                                                                                                                                          |
| <i>portOutput</i> | mask of GPIO output pins. Each bit represents one pin. For each bit: <ul style="list-style-type: none"> <li>• 0: pin output will not be changed.</li> <li>• 1: pin output logic level will be reversed.</li> <li>• LSB: pin 0</li> <li>• MSB: pin 31</li> </ul> |

```
30.2.3.15 static uint32_t GPIO_HAL_ReadPinInput (GPIO_Type * base, uint32_t pin)
 [inline], [static]
```

## GPIO HAL driver

### Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
| <i>pin</i>  | GPIO port pin number                   |

### Returns

GPIO port input value

- 0: Pin logic level is 0, or is not configured for use by digital function.
- 1: Pin logic level is 1

**30.2.3.16** `static uint32_t GPIO_HAL_ReadPortInput ( GPIO_Type * base ) [inline], [static]`

This function gets all 32-pin input as a 32-bit integer.

### Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | GPIO base pointer(PTA, PTB, PTC, etc.) |
|-------------|----------------------------------------|

### Returns

GPIO port input data. Each bit represents one pin. For each bit:

- 0: Pin logic level is 0, or is not configured for use by digital function.
- 1: Pin logic level is 1.
- LSB: pin 0
- MSB: pin 31

## 30.3 GPIO Peripheral driver

### 30.3.1 Overview

This section describes the programming interface of the GPIO Peripheral driver. The GPIO Peripheral driver configures pins to digital input/output and provides API functions for input/output operations.

### 30.3.2 GPIO Pin Definitions

Define GPIO pins according to the target board configuration and ensure that the definitions are correct. Define a header file to store the GPIO pin names and the input/output configuration arrays defined in source files.

Include this header file in source files where you want to use GPIO driver to operate GPIO pins.

GPIO pin header file example:

```
// Feel free to change the pin names as what you want
enum _gpio_pins
{
 kGpioLED1 = GPIO_MAKE_PIN(HW_PORTC, 0x0),
 kGpioLED2 = GPIO_MAKE_PIN(HW_PORTC, 0x1),
 kGpioLED3 = GPIO_MAKE_PIN(HW_PORTC, 0x2),
 kGpioLED4 = GPIO_MAKE_PIN(HW_PORTC, 0x3),
};

// Extern input/output arrays defined in source files.
extern gpio_input_pin_t inputPin[];
extern gpio_output_pin_t outputPin[];
```

### 30.3.3 GPIO Initialization

1. To initialize the GPIO driver, define two arrays, the `gpio_input_pin_t` `inputPin[]`, and the `gpio_output_pin_t` `outputPin[]`.
2. Then, call the `GPIO_DRV_Init()` function and pass these two arrays.

This is an example of the `inputPin` and `outputPin` array definition:

```
#include "gpio/fsl_gpio_driver.h"
#include "gpio_pin_header_file.h"

// Configure kGpioPTA2 as a digital input and enable the interrupt on the rising edge.
gpio_input_pin_t inputPin[] = {
 {
 .pinName = kGpioPTA2,
 .config.isPullEnable = false,
 .config.pullSelect = kPortPullDown,
 .config.isPassiveFilterEnabled = false,
 .config.interrupt = kPortIntRisingEdge,
 },
 {
 //Note: This pinName must be defined here to indicate end of array.
 .pinName = GPIO_PINS_OUT_OF_RANGE,
 }
}
```

## GPIO Peripheral driver

```

};

// Configure the kGpioLED4 and kGpioPTB9 as a digital output and enable the high drive strength.
gpio_output_pin_t outputPin[] = {
 {
 .pinName = kGpioLED4,
 .config.outputLogic = 0,
 .config.slewRate = kPortFastSlewRate,
 .config.driveStrength = kPortHighDriveStrength,
 .config.interrupt = kPortIntDisabled,
 },
 {
 .pinName = kGpioPTB9,
 .config.outputLogic = 0,
 .config.slewRate = kPortFastSlewRate,
 .config.driveStrength = kPortHighDriveStrength,
 .config.interrupt = kPortIntDisabled,
 },
 {
 //Note: This pinName must be defined here to indicate the end of array.
 .pinName = GPIO_PINS_OUT_OF_RANGE,
 }
};

// Initializes GPIO pins.
GPIO_DRV_Init(inputPin, outputPin);

```

<note> If the digital filter is enabled, the digital filter clock source and width must be configured before calling the GPIO\_DRV\_Init function. To configure the digital filter, use this API function from porting the HAL driver. Each pin in the same port shares the same digital filter settings.</note>

```

void PORT_HAL_SetDigitalFilterClock(uint32_t baseAddr, port_digital_filter_clock_source_t clockSource);
void PORT_HAL_SetDigitalFilterWidth(uint32_t baseAddr, uint8_t width);

```

### 30.3.4 Output Operations

To use the output operation, configure the target GPIO pin as a digital output in the GPIO\_DRV\_Init function. The output operations include set, clear, and toggle of the output logic level. Three API functions are provided for these operations:

```

void GPIO_DRV_SetPinOutput(uint32_t pinName);
void GPIO_DRV_ClearPinOutput(uint32_t pinName);
void GPIO_DRV_TogglePinOutput(uint32_t pinName);

```

These functions are used when the logic level of the GPIO output is known.

Otherwise, a different function is provided to configure the output logic level according to a passed parameter:

```

void GPIO_DRV_WritePinOutput(uint32_t pinName, uint32_t output);

```

Use this function to change the GPIO output according to the results of other code. Pass an integer as the "uint32\_t output" parameter. If that integer is not 0, it generates the high logic. If the integer is 0, it generates the low logic.

### 30.3.5 Input Operations

To use the input operation, configure the target GPIO pin as a digital input in the `GPIO_DRV_Init` function. For the input operation, this is the most commonly used API function:

```
uint32_t GPIO_DRV_ReadPinInput(uint32_t pinName);
```

This function returns the logic level read from a specific GPIO pin.

If the digital filter is enabled, use this function to disable it:

```
void GPIO_DRV_SetDigitalFilterCmd(uint32_t pinName, bool isDigitalFilterEnabled);
```

### 30.3.6 GPIO Interrupt

Enable a specific pin interrupt in GPIO initialization structures. Both output and input can trigger an interrupt. This API function clears the interrupt flag inside the interrupt handler:

```
void GPIO_DRV_ClearPinIntFlag(uint32_t pinName);
```

## Files

### GPIO Pin Macros

- #define [GPIO\\_PINS\\_OUT\\_OF\\_RANGE](#) (0xFFFFFFFFU)  
*Indicates the end of a pin configuration structure.*
- #define [GPIO\\_PORT\\_SHIFT](#) (0x8U)  
*Bits shifted for the GPIO port number.*
- #define [GPIO\\_MAKE\\_PIN](#)(r, p) (((r) << [GPIO\\_PORT\\_SHIFT](#)) | (p))  
*Combines the port number and the pin number into a single scalar value.*
- #define [GPIO\\_EXTRACT\\_PORT](#)(v) (((v) >> [GPIO\\_PORT\\_SHIFT](#)) & 0xFFU)  
*Extracts the port number from a combined port and pin value.*
- #define [GPIO\\_EXTRACT\\_PIN](#)(v) ((v) & 0xFFU)  
*Extracts the pin number from a combined port and pin value.*

### Initialization

- void [GPIO\\_DRV\\_Init](#) (const [gpio\\_input\\_pin\\_user\\_config\\_t](#) \*inputPins, const [gpio\\_output\\_pin\\_user\\_config\\_t](#) \*outputPins)  
*Initializes all GPIO pins used by the board.*
- void [GPIO\\_DRV\\_InputPinInit](#) (const [gpio\\_input\\_pin\\_user\\_config\\_t](#) \*inputPin)  
*Initializes one GPIO input pin used by the board.*
- void [GPIO\\_DRV\\_OutputPinInit](#) (const [gpio\\_output\\_pin\\_user\\_config\\_t](#) \*outputPin)  
*Initializes one GPIO output pin used by the board.*

### Pin Direction

- [gpio\\_pin\\_direction\\_t](#) [GPIO\\_DRV\\_GetPinDir](#) (uint32\_t pinName)  
*Gets the current direction of the individual GPIO pin.*
- void [GPIO\\_DRV\\_SetPinDir](#) (uint32\_t pinName, [gpio\\_pin\\_direction\\_t](#) direction)  
*Sets the current direction of the individual GPIO pin.*

### Output Operations

- void [GPIO\\_DRV\\_WritePinOutput](#) (uint32\_t pinName, uint32\_t output)  
*Sets the output level of the individual GPIO pin to the logic 1 or 0.*
- void [GPIO\\_DRV\\_SetPinOutput](#) (uint32\_t pinName)  
*Sets the output level of the individual GPIO pin to the logic 1.*
- void [GPIO\\_DRV\\_ClearPinOutput](#) (uint32\_t pinName)  
*Sets the output level of the individual GPIO pin to the logic 0.*
- void [GPIO\\_DRV\\_TogglePinOutput](#) (uint32\_t pinName)  
*Reverses current output logic of the individual GPIO pin.*

### Input Operations

- uint32\_t [GPIO\\_DRV\\_ReadPinInput](#) (uint32\_t pinName)  
*Reads the current input value of the individual GPIO pin.*

## Interrupt

- bool [GPIO\\_DRV\\_IsPinIntPending](#) (uint32\_t pinName)  
*Reads the individual pin-interrupt status flag.*
- void [GPIO\\_DRV\\_ClearPinIntFlag](#) (uint32\_t pinName)  
*Clears the individual GPIO pin interrupt status flag.*

## 30.3.7 Data Structure Documentation

### 30.3.7.1 struct gpio\_input\_pin\_t

Although every pin is configurable, valid configurations depend on a specific device. Users should check the related reference manual to ensure that the specific feature is valid in an individual pin. A configuration of unavailable features is harmless, but takes no effect.

### 30.3.7.2 struct gpio\_output\_pin\_t

Although every pin is configurable, valid configurations depend on a specific device. Users should check the related reference manual to ensure that the specific feature is valid in an individual pin. The configuration of unavailable features is harmless, but takes no effect.

#### Data Fields

- uint32\_t [outputLogic](#)  
*Set default output logic.*

#### 30.3.7.2.0.128 Field Documentation

##### 30.3.7.2.0.128.1 uint32\_t gpio\_output\_pin\_t::outputLogic

### 30.3.7.3 struct gpio\_input\_pin\_user\_config\_t

Although the pinName is defined as a uint32\_t type, values assigned to the pinName should be the enumeration names defined in the enum `_gpio_pins`.

#### Data Fields

- uint32\_t [pinName](#)  
*Virtual pin name from enumeration defined by the user.*
- [gpio\\_input\\_pin\\_t config](#)  
*Input pin configuration structure.*

## GPIO Peripheral driver

### 30.3.7.3.0.129 Field Documentation

30.3.7.3.0.129.1 `uint32_t gpio_input_pin_user_config_t::pinName`

30.3.7.3.0.129.2 `gpio_input_pin_t gpio_input_pin_user_config_t::config`

### 30.3.7.4 struct `gpio_output_pin_user_config_t`

Although the `pinName` is defined as a `uint32_t` type, values assigned to the `pinName` should be the enumeration names defined in the enum `_gpio_pins`.

#### Data Fields

- `uint32_t pinName`  
*Virtual pin name from enumeration defined by the user.*
- `gpio_output_pin_t config`  
*Input pin configuration structure.*

### 30.3.7.4.0.130 Field Documentation

30.3.7.4.0.130.1 `uint32_t gpio_output_pin_user_config_t::pinName`

30.3.7.4.0.130.2 `gpio_output_pin_t gpio_output_pin_user_config_t::config`

## 30.3.8 Macro Definition Documentation

30.3.8.1 `#define GPIO_PINS_OUT_OF_RANGE (0xFFFFFFFFU)`

30.3.8.2 `#define GPIO_PORT_SHIFT (0x8U)`

30.3.8.3 `#define GPIO_MAKE_PIN( r, p ) (((r) << GPIO_PORT_SHIFT) | (p))`

30.3.8.4 `#define GPIO_EXTRACT_PORT( v ) (((v) >> GPIO_PORT_SHIFT) & 0xFFU)`

30.3.8.5 `#define GPIO_EXTRACT_PIN( v ) ((v) & 0xFFU)`

## 30.3.9 Function Documentation

30.3.9.1 `void GPIO_DRV_Init ( const gpio_input_pin_user_config_t * inputPins, const gpio_output_pin_user_config_t * outputPins )`

To initialize the GPIO driver, define two arrays similar to the `gpio_input_pin_user_config_t` `inputPin[]` array and the `gpio_output_pin_user_config_t` `outputPin[]` array in the user file. Then, call the `GPIO_DRV_Init()` function and pass in the two arrays. If the input or output pins are not needed, pass in a `NULL`.

This is an example to define an input pin array:

```
// Configure the kGpioPTA2 as digital input.
gpio_input_pin_user_config_t inputPin[] = {
 {
 .pinName = kGpioPTA2,
 .config.isPullEnable = false,
 .config.pullSelect = kPortPullDown,
 .config.isPassiveFilterEnabled = false,
 .config.interrupt = kPortIntDisabled,
 },
 {
 // Note: This pinName must be defined here to indicate the end of the array.
 .pinName = GPIO_PINS_OUT_OF_RANGE,
 }
};
```

### Parameters

|                   |                           |
|-------------------|---------------------------|
| <i>inputPins</i>  | input GPIO pins pointer.  |
| <i>outputPins</i> | output GPIO pins pointer. |

### 30.3.9.2 void GPIO\_DRV\_InputPinInit ( const gpio\_input\_pin\_user\_config\_t \* *inputPin* )

#### Parameters

|                 |                          |
|-----------------|--------------------------|
| <i>inputPin</i> | input GPIO pins pointer. |
|-----------------|--------------------------|

### 30.3.9.3 void GPIO\_DRV\_OutputPinInit ( const gpio\_output\_pin\_user\_config\_t \* *outputPin* )

#### Parameters

|                  |                           |
|------------------|---------------------------|
| <i>outputPin</i> | output GPIO pins pointer. |
|------------------|---------------------------|

### 30.3.9.4 gpio\_pin\_direction\_t GPIO\_DRV\_GetPinDir ( uint32\_t *pinName* )

#### Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

#### Returns

GPIO directions.

- kGpioDigitalInput: corresponding pin is set as digital input.
- kGpioDigitalOutput: corresponding pin is set as digital output.

---

## GPIO Peripheral driver

30.3.9.5 void GPIO\_DRV\_SetPinDir ( uint32\_t *pinName*, gpio\_pin\_direction\_t *direction* )

Parameters

|                  |                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pinName</i>   | GPIO pin name defined by the user in the GPIO pin enumeration list.                                                                                                                                           |
| <i>direction</i> | GPIO directions. <ul style="list-style-type: none"> <li>• kGpioDigitalInput: corresponding pin is set as digital input.</li> <li>• kGpioDigitalOutput: corresponding pin is set as digital output.</li> </ul> |

**30.3.9.6 void GPIO\_DRV\_WritePinOutput ( uint32\_t *pinName*, uint32\_t *output* )**

Parameters

|                |                                                                                                                                                                                       |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list.                                                                                                                   |
| <i>output</i>  | pin output logic level. <ul style="list-style-type: none"> <li>• 0: corresponding pin output low logic level.</li> <li>• Non-0: corresponding pin output high logic level.</li> </ul> |

**30.3.9.7 void GPIO\_DRV\_SetPinOutput ( uint32\_t *pinName* )**

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

**30.3.9.8 void GPIO\_DRV\_ClearPinOutput ( uint32\_t *pinName* )**

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

**30.3.9.9 void GPIO\_DRV\_TogglePinOutput ( uint32\_t *pinName* )**

Parameters

---

## GPIO Peripheral driver

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

### 30.3.9.10 uint32\_t GPIO\_DRV\_ReadPinInput ( uint32\_t *pinName* )

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

Returns

GPIO port input value.

- 0: Pin logic level is 0, or is not configured for use by digital function.
- 1: Pin logic level is 1.

### 30.3.9.11 bool GPIO\_DRV\_IsPinIntPending ( uint32\_t *pinName* )

If a pin is configured to generate the DMA request, the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic one is written to that flag. If configured for a level sensitive interrupt that remains asserted, the flag is set again immediately.

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

Returns

current pin interrupt status flag

- 0: interrupt is not detected.
- 1: interrupt is detected.

### 30.3.9.12 void GPIO\_DRV\_ClearPinIntFlag ( uint32\_t *pinName* )

Parameters

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>pinName</i> | GPIO pin name defined by the user in the GPIO pin enumeration list. |
|----------------|---------------------------------------------------------------------|

### **30.3.10 Variable Documentation**

**30.3.10.1** `GPIO_Type* const g_gpioBase[GPIO_INSTANCE_COUNT]`

**30.3.10.2** `PORT_Type* const g_portBase[PORT_INSTANCE_COUNT]`

## Chapter 31 Hardware Timer Manager Driver

### 31.1 Overview

The Kinetis SDK provides the Hardware Timer Manager driver for various timer modules.

#### Modules

- [Hardware Timer Manager Driver](#)
- [Hardware Timer Manager Interrupt handlers](#)

#### Files

- file [fsl\\_hwtimer.h](#)

#### Data Structures

- struct [hwtimer\\_ptr\\_t](#)  
*HwTimer structure. [More...](#)*
- struct [hwtimer\\_time\\_ptr\\_t](#)  
*Hwtimer\_time structure. [More...](#)*
- struct [hwtimer\\_devif\\_ptr\\_t](#)  
*hwtimer\_devif structure. [More...](#)*

#### Macros

- #define [HWTIMER\\_LL\\_CONTEXT\\_LEN](#) 5U  
*HwTimer low level context data length definition.*

#### Typedefs

- typedef void(\* [hwtimer\\_callback\\_t](#))(void \*p)  
*Definition for low level context data length.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_init\\_t](#))([hwtimer\\_t](#) \*hwtimer, uint32\_t id, void \*data)  
*Type defines initialization function for devif structure.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_deinit\\_t](#))([hwtimer\\_t](#) \*hwtimer)  
*Type defines deinitialization function for devif structure.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_set\\_div\\_t](#))([hwtimer\\_t](#) \*hwtimer, uint32\_t period)  
*Type defines set\_div function for devif structure.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_start\\_t](#))([hwtimer\\_t](#) \*hwtimer)  
*Type defines start function for devif structure.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_stop\\_t](#))([hwtimer\\_t](#) \*hwtimer)  
*Type defines stop function for devif structure.*
- typedef [\\_hwtimer\\_error\\_code\\_t](#)(\* [hwtimer\\_devif\\_reset\\_t](#))([hwtimer\\_t](#) \*hwtimer)

## Overview

- Type defines reset function for devif structure.*

• typedef `_hwtimer_error_code_t(* hwtimer_devif_get_time_t)(hwtimer_t *hwtimer, hwtimer_time_t *time)`

*Type defines get\_time function for devif structure.*

## Enumerations

- enum `_hwtimer_error_code_t` {

`kHwtimerSuccess,`

`kHwtimerInvalidInput,`

`kHwtimerInvalidPointer,`

`kHwtimerClockManagerError,`

`kHwtimerRegisterHandlerError,`

`kHwtimerUnknown` }

*HwTimer error codes definition.*

## Functions

- `_hwtimer_error_code_t HWTIMER_SYS_Init` (`hwtimer_t *hwtimer`, const `hwtimer_devif_t *kDevif`, `uint32_t id`, `void *data`)

*Initializes a caller allocated structure according to given parameters.*
- `_hwtimer_error_code_t HWTIMER_SYS_Deinit` (`hwtimer_t *hwtimer`)

*Deinitializes the HwTimer.*
- `_hwtimer_error_code_t HWTIMER_SYS_SetPeriod` (`hwtimer_t *hwtimer`, `uint32_t period`)

*Sets the period of the HwTimer.*
- `uint32_t HWTIMER_SYS_GetPeriod` (`hwtimer_t *hwtimer`)

*Gets the period of the HwTimer.*
- `_hwtimer_error_code_t HWTIMER_SYS_Start` (`hwtimer_t *hwtimer`)

*Enables the timer and leaves it running.*
- `_hwtimer_error_code_t HWTIMER_SYS_Stop` (`hwtimer_t *hwtimer`)

*The timer stops counting after this function is called.*
- `uint32_t HWTIMER_SYS_GetModulo` (`hwtimer_t *hwtimer`)

*The function returns period of the timer in sub-ticks.*
- `_hwtimer_error_code_t HWTIMER_SYS_GetTime` (`hwtimer_t *hwtimer`, `hwtimer_time_t *time`)

*The function reads the current value of the HwTimer.*
- `uint32_t HWTIMER_SYS_GetTicks` (`hwtimer_t *hwtimer`)

*The function reads the current value of the HwTimer.*
- `_hwtimer_error_code_t HWTIMER_SYS_RegisterCallback` (`hwtimer_t *hwtimer`, `hwtimer_callback_t callbackFunc`, `void *callbackData`)

*Registers function to be called when the timer expires.*
- `_hwtimer_error_code_t HWTIMER_SYS_BlockCallback` (`hwtimer_t *hwtimer`)

*The function is used to block callbacks in circumstances when execution of the callback function is undesired.*
- `_hwtimer_error_code_t HWTIMER_SYS_UnblockCallback` (`hwtimer_t *hwtimer`)

*The function is used to unblock previously blocked callbacks.*
- `_hwtimer_error_code_t HWTIMER_SYS_CancelCallback` (`hwtimer_t *hwtimer`)

*The function cancels pending callback, if any.*

## 31.2 Data Structure Documentation

### 31.2.1 struct hwtimer\_t

This structure defines a HwTimer. The context structure is passed to all API functions (besides other parameters).

#### Warning

Application should not access members of this structure directly.

#### See Also

HWTIMER\_SYS\_init  
HWTIMER\_SYS\_deinit  
HWTIMER\_SYS\_start  
HWTIMER\_SYS\_stop  
HWTIMER\_SYS\_set\_period  
HWTIMER\_SYS\_get\_period  
HWTIMER\_SYS\_get\_modulo  
HWTIMER\_SYS\_get\_time  
HWTIMER\_SYS\_get\_ticks  
HWTIMER\_SYS\_callback\_reg  
HWTIMER\_SYS\_callback\_block  
HWTIMER\_SYS\_callback\_unblock  
HWTIMER\_SYS\_callback\_cancel

#### Data Fields

- const struct Hwtimer\_devif \* [devif](#)  
*Pointer to a device interface structure.*
- uint32\_t [clockFreq](#)  
*Timer's source clock frequency.*
- uint32\_t [divider](#)  
*Actual total divider.*
- uint32\_t [modulo](#)  
*Determine how many sub ticks are in one tick.*
- volatile uint64\_t [ticks](#)  
*Number of elapsed ticks.*
- [hwtimer\\_callback\\_t](#) [callbackFunc](#)  
*Function pointer to be called when the timer expires.*
- void \* [callbackData](#)  
*Arbitrary pointer passed as parameter to the callback function.*
- volatile int [callbackPending](#)  
*Indicate pending callback.*
- int [callbackBlocked](#)  
*Indicate blocked callback.*

## Data Structure Documentation

- `uint32_t llContext [HWTIMER_LL_CONTEXT_LEN]`  
*Private storage locations for arbitrary data keeping the context of the lower layer driver.*

### 31.2.1.0.0.131 Field Documentation

**31.2.1.0.0.131.1** `hwtimer_callback_t hwtimer_ptr_t::callbackFunc`

**31.2.1.0.0.131.2** `void* hwtimer_ptr_t::callbackData`

**31.2.1.0.0.131.3** `volatile int hwtimer_ptr_t::callbackPending`

If the timer overflows when callbacks are blocked the callback becomes pending.

**31.2.1.0.0.131.4** `int hwtimer_ptr_t::callbackBlocked`

**31.2.1.0.0.131.5** `uint32_t hwtimer_ptr_t::llContext[HWTIMER_LL_CONTEXT_LEN]`

### 31.2.2 struct `hwtimer_time_t`

HwTimer time structure represents a time stamp consisting of timer elapsed periods (TICKS) and current value of the timer counter (subTicks).

See Also

[HWTIMER\\_SYS\\_GetTime](#)

### Data Fields

- `uint64_t ticks`  
*Ticks of timer.*
- `uint32_t subTicks`  
*Sub ticks of timer.*

### 31.2.3 struct `hwtimer_devif_t`

Each low layer driver exports an instance of this structure initialized with pointers to API functions that the driver implements. The functions should be declared as static (not exported directly).

See Also

[HWTIMER\\_SYS\\_Init](#)  
[HWTIMER\\_SYS\\_Deinit](#)

### Data Fields

- `hwtimer_devif_init_t init`

- Function pointer to lower layer initialization.*

  - [hwtimer\\_devif\\_deinit\\_t deinit](#)

*Function pointer to lower layer de-initialization.*

  - [hwtimer\\_devif\\_set\\_div\\_t setDiv](#)

*Function pointer to lower layer set divider functionality.*

  - [hwtimer\\_devif\\_start\\_t start](#)

*Function pointer to lower layer start functionality.*

  - [hwtimer\\_devif\\_stop\\_t stop](#)

*Function pointer to lower layer stop functionality.*

  - [hwtimer\\_devif\\_get\\_time\\_t getTime](#)

*Function pointer to lower layer get time functionality.*

### 31.3 Enumeration Type Documentation

#### 31.3.1 enum \_hwtimer\_error\_code\_t

Enumerator

- kHwtimerSuccess* success
- kHwtimerInvalidInput* invalid input parameter
- kHwtimerInvalidPointer* invalid pointer
- kHwtimerClockManagerError* clock manager return error
- kHwtimerRegisterHandlerError* Interrupt handler registration returns error.
- kHwtimerUnknown* unknown error

### 31.4 Function Documentation

#### 31.4.1 \_hwtimer\_error\_code\_t HWTIMER\_SYS\_Init ( hwtimer\_t \* hwtimer, const hwtimer\_devif\_t \* kDevif, uint32\_t id, void \* data )

The device interface pointer determines the low layer driver to be used. Device interface structure is exported by each low layer driver and is opaque to the applications. See a chapter about the low layer driver below for details. Meaning of the numerical identifier varies depending on the low layer driver used. Typically, it identifies a particular timer channel to initialize. The initialization function has to be called prior to using any other API function.

Parameters

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>hwtimer</i> | [out] Returns initialized HwTimer structure handle.    |
| <i>kDevif</i>  | [in] Structure determines low layer driver to be used. |
| <i>id</i>      | [in] Numerical identifier of the timer.                |

## Function Documentation

|             |                                                |
|-------------|------------------------------------------------|
| <i>data</i> | [in] Specific data for low level of interrupt. |
|-------------|------------------------------------------------|

### Returns

success or an error code returned from low level initialization function.

### Return values

|                               |                                                |
|-------------------------------|------------------------------------------------|
| <i>kHwtimerSuccess</i>        | Success                                        |
| <i>kHwtimerInvalidInput</i>   | When input parameter HwTimer is a NULL pointer |
| <i>kHwtimerInvalidPointer</i> | When device structure points to NULL.          |

### Warning

The initialization function has to be called prior using any other API function.

### See Also

HWTIMER\_SYS\_deinit  
HWTIMER\_SYS\_start  
HWTIMER\_SYS\_stop

### 31.4.2 `_hwtimer_error_code_t HWTIMER_SYS_Deinit ( hwtimer_t * hwtimer )`

Calls the lower layer stop function to stop the timer. Then, calls the low layer de-initialization function and afterwards invalidates HwTimer structure by clearing it.

### Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

### Returns

success or an error code returned from low level DEINIT function.

### Return values

---

|                               |                                                |
|-------------------------------|------------------------------------------------|
| <i>kHwtimerSuccess</i>        | Success                                        |
| <i>kHwtimerInvalidInput</i>   | When input parameter HwTimer is a NULL pointer |
| <i>kHwtimerInvalidPointer</i> | When device structure points to NULL.          |

See Also

- [HWTIMER\\_SYS\\_Init](#)
- [HWTIMER\\_SYS\\_Start](#)
- [HWTIMER\\_SYS\\_Stop](#)

### 31.4.3 `_hwtimer_error_code_t HWTIMER_SYS_SetPeriod ( hwtimer_t * hwtimer, uint32_t period )`

The function provides a way to set up the timer to a desired period specified in microseconds. Calls the low layer driver to set up the timer divider according to the specified period.

Parameters

|                |                                                 |
|----------------|-------------------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure.              |
| <i>period</i>  | [in] Required period of timer in micro seconds. |

Returns

success or an error code returned from low level SETDIV function.

Return values

|                                   |                                                                         |
|-----------------------------------|-------------------------------------------------------------------------|
| <i>kHwtimerSuccess</i>            | Success                                                                 |
| <i>kHwtimerInvalidInput</i>       | When input parameter HwTimer or his device structure are NULL pointers. |
| <i>kHwtimerInvalidPointer</i>     | When low level SETDIV function point to NULL.                           |
| <i>kHwtimerClockManager-Error</i> | When Clock manager returns error.                                       |

See Also

- [HWTIMER\\_SYS\\_GetPeriod](#)
- [HWTIMER\\_SYS\\_GetModulo](#)
- [HWTIMER\\_SYS\\_GetTime](#)
- [HWTIMER\\_SYS\\_GetTicks](#)

---

## Function Documentation

### 31.4.4 `uint32_t HWTIMER_SYS_GetPeriod ( hwtimer_t * hwtimer )`

The function returns the current period of the timer in microseconds calculated from the base frequency and actual divider settings of the timer.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

already set period of HwTimer.

Return values

|   |                                                                         |
|---|-------------------------------------------------------------------------|
| 0 | Input parameter HwTimer is NULL pointer or clock manager returns error. |
|---|-------------------------------------------------------------------------|

See Also

- [HWTIMER\\_SYS\\_SetPeriod](#)
- [HWTIMER\\_SYS\\_GetModulo](#)
- [HWTIMER\\_SYS\\_GetTime](#)
- [HWTIMER\\_SYS\\_GetTicks](#)

### 31.4.5 `_hwtimer_error_code_t HWTIMER_SYS_Start ( hwtimer_t * hwtimer )`

The timer starts counting a new period generating interrupts every time the timer rolls over.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

success or an error code returned from low level START function.

Return values

|                               |                                                |
|-------------------------------|------------------------------------------------|
| <i>kHwtimerSuccess</i>        | Success                                        |
| <i>kHwtimerInvalidInput</i>   | When input parameter HwTimer is a NULL pointer |
| <i>kHwtimerInvalidPointer</i> | When device structure points to NULL.          |

## Function Documentation

See Also

[HWTIMER\\_SYS\\_Init](#)  
[HWTIMER\\_SYS\\_Deinit](#)  
[HWTIMER\\_SYS\\_Stop](#)

### 31.4.6 `_hwtimer_error_code_t HWTIMER_SYS_Stop ( hwtimer_t * hwtimer )`

Pending interrupts and callbacks are cancelled.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

success or an error code returned from low level STOP function.

Return values

|                               |                                                |
|-------------------------------|------------------------------------------------|
| <i>kHwtimerSuccess</i>        | Success                                        |
| <i>kHwtimerInvalidInput</i>   | When input parameter HwTimer is a NULL pointer |
| <i>kHwtimerInvalidPointer</i> | When device structure points to NULL.          |

See Also

[HWTIMER\\_SYS\\_Deinit](#)  
[HWTIMER\\_SYS\\_Start](#)

### 31.4.7 `uint32_t HWTIMER_SYS_GetModulo ( hwtimer_t * hwtimer )`

It is typically called after [HWTIMER\\_SYS\\_SetPeriod\(\)](#) to obtain actual resolution of the timer in the current configuration.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

resolution of HwTimer.

Return values

|   |                                          |
|---|------------------------------------------|
| 0 | Input parameter HwTimer is NULL pointer. |
|---|------------------------------------------|

See Also

- [HWTIMER\\_SYS\\_SetPeriod](#)
- [HWTIMER\\_SYS\\_GetPeriod](#)
- [HWTIMER\\_SYS\\_GetTime](#)
- [HWTIMER\\_SYS\\_GetTicks](#)

**31.4.8 `_hwtimer_error_code_t HWTIMER_SYS_GetTime ( hwtimer_t * hwtimer, hwtimer_time_t * time )`**

Elapsed periods(ticks) and current value of the timer counter (sub-ticks) are filled into the Hwtimer\_time structure. The sub-ticks number always counts up and is reset to zero when the timer overflows regardless of the counting direction of the underlying device.

Parameters

|                |                                                                                        |
|----------------|----------------------------------------------------------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure.                                                     |
| <i>time</i>    | [out] Pointer to time structure. This value is filled with current value of the timer. |

Returns

success or an error code returned from low level GET\_TIME function.

Return values

---

## Function Documentation

|                               |                                                                         |
|-------------------------------|-------------------------------------------------------------------------|
| <i>kHwtimerSuccess</i>        | Success                                                                 |
| <i>kHwtimerInvalidInput</i>   | When input parameter HwTimer or input parameter time are NULL pointers. |
| <i>kHwtimerInvalidPointer</i> | When device structure points to NULL.                                   |

See Also

[HWTIMER\\_SYS\\_GetPeriod](#)  
[HWTIMER\\_SYS\\_GetModulo](#)  
[HWTIMER\\_SYS\\_GetTicks](#)

### 31.4.9 uint32\_t HWTIMER\_SYS\_GetTicks ( hwtimer\_t \* hwtimer )

The returned value corresponds to the lower 32 bits of elapsed periods (ticks). The value is guaranteed to be obtained without needing to mask timer interrupt. Lower layer driver is not involved at all and calling this function is considerably faster than HWTIMER\_SYS\_GetTime.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

low 32 bits of 64 bit tick value.

Return values

|   |                                               |
|---|-----------------------------------------------|
| 0 | When input parameter HwTimer is NULL pointer. |
|---|-----------------------------------------------|

See Also

### 31.4.10 \_hwtimer\_error\_code\_t HWTIMER\_SYS\_RegisterCallback ( hwtimer\_t \* hwtimer, hwtimer\_callback\_t callbackFunc, void \* callbackData )

The callback\_data is arbitrary pointer passed as parameter to the callback function.

Parameters

|                     |                                                            |
|---------------------|------------------------------------------------------------|
| <i>hwtimer</i>      | [in] Pointer to HwTimer structure.                         |
| <i>callbackFunc</i> | [in] Function pointer to be called when the timer expires. |
| <i>callbackData</i> | [in] Data pointer for the function callback_func.          |

Returns

success or an error code

Return values

|                             |                                               |
|-----------------------------|-----------------------------------------------|
| <i>kHwtimerInvalidInput</i> | When input parameter HwTimer is NULL pointer. |
| <i>kHwtimerSuccess</i>      | When registration callback succeed.           |

Warning

This function must not be called from a callback routine.

- [HWTIMER\\_SYS\\_UnblockCallback](#)
- [HWTIMER\\_SYS\\_CancelCallback](#)

**31.4.11 `_hwtimer_error_code_t HWTIMER_SYS_BlockCallback ( hwtimer_t * hwtimer )`**

If the timer overflows when callbacks are blocked the callback becomes pending.

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

success or an error code

## Function Documentation

Return values

|                             |                                               |
|-----------------------------|-----------------------------------------------|
| <i>kHwtimerInvalidInput</i> | When input parameter HwTimer is NULL pointer. |
| <i>kHwtimerSuccess</i>      | When callback block succeed.                  |

Warning

This function must not be called from a callback routine.

### 31.4.12 `_hwtimer_error_code_t HWTIMER_SYS_UnblockCallback ( hwtimer_t * hwtimer )`

If there is a callback pending, it gets immediately executed. This function must not be called from a callback routine (it does not make sense to do so anyway as callback function never gets executed while callbacks are blocked).

Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

Returns

success or an error code

Return values

|                             |                                               |
|-----------------------------|-----------------------------------------------|
| <i>kHwtimerInvalidInput</i> | When input parameter HwTimer is NULL pointer. |
| <i>kHwtimerSuccess</i>      | When callback unblock succeed.                |

Warning

This function must not be called from a callback routine.

hwtimer )`

## Function Documentation

### Parameters

|                |                                    |
|----------------|------------------------------------|
| <i>hwtimer</i> | [in] Pointer to HwTimer structure. |
|----------------|------------------------------------|

### Returns

success or an error code

### Return values

|                             |                                               |
|-----------------------------|-----------------------------------------------|
| <i>kHwtimerInvalidInput</i> | When input parameter HwTimer is NULL pointer. |
| <i>kHwtimerSuccess</i>      | When callback cancel succeed.                 |

### Warning

This function must not be called from a callback routine (it does not make sense to do so anyway as callback function never gets executed while callbacks are blocked).

## 31.5 Hardware Timer Manager Driver

The Hardware Timer Manager driver provides common APIs for various timer modules.

### 31.5.1 HwTimer Overview

The driver consists of two layers:

- The hardware-specific lower layer contains implementation specific to a particular timer module. An application should not use this layer.
- The generic upper layer provides an abstraction to call the appropriate lower layer functions while passing the appropriate context structure. This chapter describes the generic upper layer only.

---

## Hardware Timer Manager Interrupt handlers

### 31.6 Hardware Timer Manager Interrupt handlers

The Hardware Timer Manager interrupt handlers provides interrupt handlers for the Hardware Timer Managers.

#### 31.6.1 Hardware Timer Manager Driver Interrupt handler overview

The Hardware Timer Manager interrupt handlers are not included in the KSDK library. The user has to include them when building the application.

---

## Chapter 32

# Inter-Integrated Circuit (I2C)

### 32.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Inter-Integrated Circuit (I2C) block of Kinetis devices.

#### Modules

- [I2C HAL driver](#)
- [I2C Master peripheral](#)
- [I2C Slave peripheral driver](#)

## I2C HAL driver

### 32.2 I2C HAL driver

#### 32.2.1 Overview

This section describes the programming interface of the I2C HAL driver.

#### 32.2.2 I2C ICR Table

| ICR (hex) | SCL divider | SDA hold value | SCL start hold value | SCL stop hold value |
|-----------|-------------|----------------|----------------------|---------------------|
| 00        | 20          | 7              | 6                    | 11                  |
| 01        | 22          | 7              | 7                    | 12                  |
| 02        | 24          | 8              | 8                    | 13                  |
| 03        | 26          | 8              | 9                    | 14                  |
| 04        | 28          | 9              | 10                   | 15                  |
| 05        | 30          | 9              | 11                   | 16                  |
| 06        | 34          | 10             | 13                   | 18                  |
| 07        | 40          | 10             | 16                   | 21                  |

#### 32.2.3 I2C Clock rate formulas

I2C baud rate =  $\text{bus\_clock\_Hz} / (\text{mult} * \text{SCL\_divider})$

SDA hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SDA\_hold\_value}$

SCL start hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SCL\_start\_hold\_value}$

SCL stop hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SCL\_stop\_hold\_value}$

## Enumerations

- enum `i2c_status_t` {  
`kStatus_I2C_Success` = 0x0U,  
`kStatus_I2C_Initialized` = 0x1U,  
`kStatus_I2C_Fail` = 0x2U,  
`kStatus_I2C_Busy` = 0x3U,  
`kStatus_I2C_Timeout` = 0x4U,  
`kStatus_I2C_ReceivedNak` = 0x5U,  
`kStatus_I2C_SlaveTxUnderrun` = 0x6U,  
`kStatus_I2C_SlaveRxOverrun` = 0x7U,  
`kStatus_I2C_ArbitrationLost` = 0x8U,  
`kStatus_I2C_StopSignalFail` = 0x9U,  
`kStatus_I2C_Idle` = 0xAU,  
`kStatus_I2C_NoReceiveInProgress` = 0xBU,  
`kStatus_I2C_NoSendInProgress` = 0xCU }  
*I2C status return codes.*
- enum `i2c_status_flag_t`  
*I2C status flags.*
- enum `i2c_direction_t` {  
`kI2CReceive` = 0U,  
`kI2CSend` = 1U }  
*Direction of master and slave transfers.*

## Module controls

- void `I2C_HAL_Init` (I2C\_Type \*base)  
*Restores the I2C peripheral to reset state.*
- static void `I2C_HAL_Enable` (I2C\_Type \*base)  
*Enables the I2C module operation.*
- static void `I2C_HAL_Disable` (I2C\_Type \*base)  
*Disables the I2C module operation.*

## Pin functions

- static void `I2C_HAL_SetGlitchWidth` (I2C\_Type \*base, uint8\_t glitchWidth)  
*Controls the width of the programmable glitch filter.*

## Low power

- static void `I2C_HAL_SetWakeupCmd` (I2C\_Type \*base, bool enable)  
*Controls the I2C wakeup enable.*

## I2C HAL driver

### Baud rate

- void [I2C\\_HAL\\_SetBaudRate](#) (I2C\_Type \*base, uint32\_t sourceClockInHz, uint32\_t kbps, uint32\_t \*absoluteError\_Hz)  
*Sets the I2C bus frequency for master transactions.*
- static void [I2C\\_HAL\\_SetFreqDiv](#) (I2C\_Type \*base, uint8\_t mult, uint8\_t icr)  
*Sets the I2C baud rate multiplier and table entry.*
- static void [I2C\\_HAL\\_SetSlaveBaudCtrlCmd](#) (I2C\_Type \*base, bool enable)  
*Slave baud rate control.*

### Bus operations

- void [I2C\\_HAL\\_SendStart](#) (I2C\_Type \*base)  
*Sends a START or a Repeated START signal on the I2C bus.*
- [i2c\\_status\\_t I2C\\_HAL\\_SendStop](#) (I2C\_Type \*base)  
*Sends a STOP signal on the I2C bus.*
- static void [I2C\\_HAL\\_SendAck](#) (I2C\_Type \*base)  
*Causes an ACK to be sent on the bus.*
- static void [I2C\\_HAL\\_SendNak](#) (I2C\_Type \*base)  
*Causes a NAK to be sent on the bus.*
- static void [I2C\\_HAL\\_SetDirMode](#) (I2C\_Type \*base, [i2c\\_direction\\_t](#) direction)  
*Selects either transmit or receive mode.*
- static [i2c\\_direction\\_t I2C\\_HAL\\_GetDirMode](#) (I2C\_Type \*base)  
*Returns the currently selected transmit or receive mode.*

### Data transfer

- static [uint8\\_t I2C\\_HAL\\_ReadByte](#) (I2C\_Type \*base)  
*Returns the last byte of data read from the bus and initiate another read.*
- static void [I2C\\_HAL\\_WriteByte](#) (I2C\_Type \*base, uint8\_t byte)  
*Writes one byte of data to the I2C bus.*
- [uint8\\_t I2C\\_HAL\\_ReadByteBlocking](#) (I2C\_Type \*base)  
*Returns the last byte of data read from the bus and initiate another read.*
- bool [I2C\\_HAL\\_WriteByteBlocking](#) (I2C\_Type \*base, uint8\_t byte)  
*Writes one byte of data to the I2C bus and wait till that byte is transferred successfully.*
- [i2c\\_status\\_t I2C\\_HAL\\_MasterReceiveDataPolling](#) (I2C\_Type \*base, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Performs a polling receive transaction on the I2C bus.*
- [i2c\\_status\\_t I2C\\_HAL\\_MasterSendDataPolling](#) (I2C\_Type \*base, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, const uint8\_t \*txBuff, uint32\_t txSize)  
*Performs a polling send transaction on the I2C bus.*
- [i2c\\_status\\_t I2C\\_HAL\\_SlaveSendDataPolling](#) (I2C\_Type \*base, const uint8\_t \*txBuff, uint32\_t txSize)  
*Send out multiple bytes of data using polling method.*
- [i2c\\_status\\_t I2C\\_HAL\\_SlaveReceiveDataPolling](#) (I2C\_Type \*base, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Receive multiple bytes of data using polling method.*

## Slave address

- void [I2C\\_HAL\\_SetAddress7bit](#) (I2C\_Type \*base, uint8\_t address)  
*Sets the primary 7-bit slave address.*
- void [I2C\\_HAL\\_SetAddress10bit](#) (I2C\_Type \*base, uint16\_t address)  
*Sets the primary slave address and enables 10-bit address mode.*
- static void [I2C\\_HAL\\_SetExtensionAddrCmd](#) (I2C\_Type \*base, bool enable)  
*Enables or disables the extension address (10-bit).*
- static bool [I2C\\_HAL\\_GetExtensionAddrCmd](#) (I2C\_Type \*base)  
*Returns whether the extension address is enabled or not.*
- static void [I2C\\_HAL\\_SetGeneralCallCmd](#) (I2C\_Type \*base, bool enable)  
*Controls whether the general call address is recognized.*
- static void [I2C\\_HAL\\_SetRangeMatchCmd](#) (I2C\_Type \*base, bool enable)  
*Enables or disables the slave address range matching.*
- static void [I2C\\_HAL\\_SetUpperAddress7bit](#) (I2C\_Type \*base, uint8\_t address)  
*Sets the upper slave address.*

## Status

- static bool [I2C\\_HAL\\_GetStatusFlag](#) (I2C\_Type \*base, [i2c\\_status\\_flag\\_t](#) statusFlag)  
*Gets the I2C status flag state.*
- static bool [I2C\\_HAL\\_IsMaster](#) (I2C\_Type \*base)  
*Returns whether the I2C module is in master mode.*
- static void [I2C\\_HAL\\_ClearArbitrationLost](#) (I2C\_Type \*base)  
*Clears the arbitration lost flag.*

## Interrupt

- static void [I2C\\_HAL\\_SetIntCmd](#) (I2C\_Type \*base, bool enable)  
*Enables or disables I2C interrupt requests.*
- static bool [I2C\\_HAL\\_GetIntCmd](#) (I2C\_Type \*base)  
*Returns whether the I2C interrupts are enabled.*
- static bool [I2C\\_HAL\\_IsIntPending](#) (I2C\_Type \*base)  
*Returns the current I2C interrupt flag.*
- static void [I2C\\_HAL\\_ClearInt](#) (I2C\_Type \*base)  
*Clears the I2C interrupt if set.*

## 32.2.4 Enumeration Type Documentation

### 32.2.4.1 enum i2c\_status\_t

Enumerator

- kStatus\_I2C\_Success*** I2C operation has no error.
- kStatus\_I2C\_Initialized*** Current I2C is already initialized by one task.
- kStatus\_I2C\_Fail*** I2C operation failed.

## I2C HAL driver

*kStatus\_I2C\_Busy* The master is already performing a transfer.

*kStatus\_I2C\_Timeout* The transfer timed out.

*kStatus\_I2C\_ReceivedNak* The slave device sent a NAK in response to a byte.

*kStatus\_I2C\_SlaveTxUnderrun* I2C Slave TX Underrun error.

*kStatus\_I2C\_SlaveRxOverrun* I2C Slave RX Overrun error.

*kStatus\_I2C\_ArbitrationLost* I2C Arbitration Lost error.

*kStatus\_I2C\_StopSignalFail* I2C STOP signal could not release bus.

*kStatus\_I2C\_Idle* I2C Slave Bus is Idle.

*kStatus\_I2C\_NoReceiveInProgress* Attempt to abort a receiving when no transfer was in progress.

*kStatus\_I2C\_NoSendInProgress* Attempt to abort a sending when no transfer was in progress.

### 32.2.4.2 enum i2c\_status\_flag\_t

### 32.2.4.3 enum i2c\_direction\_t

Enumerator

*kI2CReceive* Master transmit, slave receive.

*kI2CSend* Master receive, slave transmit.

## 32.2.5 Function Documentation

### 32.2.5.1 void I2C\_HAL\_Init ( I2C\_Type \* *base* )

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

### 32.2.5.2 static void I2C\_HAL\_Enable ( I2C\_Type \* *base* ) [inline], [static]

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

### 32.2.5.3 static void I2C\_HAL\_Disable ( I2C\_Type \* *base* ) [inline], [static]

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**32.2.5.4 static void I2C\_HAL\_SetGlitchWidth ( I2C\_Type \* *base*, uint8\_t *glitchWidth* )  
[inline], [static]**

Controls the width of the glitch, in terms of bus clock cycles, that the filter must absorb. The filter does not allow any glitch whose size is less than or equal to this width setting, to pass.

Parameters

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <i>base</i>        | The I2C peripheral base pointer                                                                             |
| <i>glitchWidth</i> | Maximum width in bus clock cycles of the glitches that is filtered. Pass zero to disable the glitch filter. |

**32.2.5.5 static void I2C\_HAL\_SetWakeupCmd ( I2C\_Type \* *base*, bool *enable* )  
[inline], [static]**

The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs.

Parameters

|               |                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer.                                                                                                                      |
| <i>enable</i> | true - Enables the wakeup function in low power mode.<br>false - Normal operation. No interrupt is generated when address matching in low power mode. |

**32.2.5.6 void I2C\_HAL\_SetBaudRate ( I2C\_Type \* *base*, uint32\_t *sourceClockInHz*,  
uint32\_t *kbps*, uint32\_t \* *absoluteError\_Hz* )**

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

## I2C HAL driver

|                         |                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sourceClockIn-Hz</i> | I2C source input clock in Hertz                                                                                                                                                    |
| <i>kbps</i>             | Requested bus frequency in kilohertz. Common values are either 100 or 400.                                                                                                         |
| <i>absoluteError-Hz</i> | If this parameter is not NULL, it is filled in with the difference in Hertz between the requested bus frequency and the closest frequency possible given available divider values. |

### 32.2.5.7 static void I2C\_HAL\_SetFreqDiv ( I2C\_Type \* *base*, uint8\_t *mult*, uint8\_t *icr* ) [inline], [static]

Use this function to set the I2C bus frequency register values directly, if they are known in advance.

Parameters

|             |                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i> | The I2C peripheral base pointer                                                                                                             |
| <i>mult</i> | Value of the MULT bitfield, ranging from 0-2.                                                                                               |
| <i>icr</i>  | The ICR bitfield value, which is the index into an internal table in the I2C hardware that selects the baud rate divisor and SCL hold time. |

### 32.2.5.8 static void I2C\_HAL\_SetSlaveBaudCtrlCmd ( I2C\_Type \* *base*, bool *enable* ) [inline], [static]

Enables an independent slave mode baud rate at the maximum frequency. This forces clock stretching on the SCL in very fast I2C modes.

Parameters

|               |                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer                                                                                                                            |
| <i>enable</i> | true - Slave baud rate is independent of the master baud rate;<br>false - The slave baud rate follows the master baud rate and clock stretching may occur. |

### 32.2.5.9 void I2C\_HAL\_SendStart ( I2C\_Type \* *base* )

This function is used to initiate a new master mode transfer by sending the START signal. It is also used to send a Repeated START signal when a transfer is already in progress.

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**32.2.5.10** `i2c_status_t I2C_HAL_SendStop ( I2C_Type * base )`

This function changes the direction to receive.

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

Returns

Whether the sending of STOP single is success or not.

**32.2.5.11** `static void I2C_HAL_SendAck ( I2C_Type * base ) [inline], [static]`

This function specifies that an ACK signal is sent in response to the next received byte.

Note that the behavior of this function is changed when the I2C peripheral is placed in Fast ACK mode. In this case, this function causes an ACK signal to be sent in response to the current byte, rather than the next received byte.

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**32.2.5.12** `static void I2C_HAL_SendNak ( I2C_Type * base ) [inline], [static]`

This function specifies that a NAK signal is sent in response to the next received byte.

Note that the behavior of this function is changed when the I2C peripheral is placed in the Fast ACK mode. In this case, this function causes an NAK signal to be sent in response to the current byte, rather than the next received byte.

Parameters

---

## I2C HAL driver

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**32.2.5.13** `static void I2C_HAL_SetDirMode ( I2C_Type * base, i2c_direction_t direction ) [inline], [static]`

### Parameters

|                  |                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>      | The I2C peripheral base pointer.                                                                                                                                               |
| <i>direction</i> | Specifies either transmit mode or receive mode. The valid values are: <ul style="list-style-type: none"> <li>• #kI2CTransmit</li> <li>• <a href="#">kI2CReceive</a></li> </ul> |

**32.2.5.14** `static i2c_direction_t I2C_HAL_GetDirMode ( I2C_Type * base ) [inline], [static]`

### Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>base</i> | The I2C peripheral base pointer. |
|-------------|----------------------------------|

### Returns

Current I2C transfer mode.

### Return values

|                               |                                                      |
|-------------------------------|------------------------------------------------------|
| <a href="#">#kI2CTransmit</a> | I2C is configured for master or slave transmit mode. |
| <a href="#">kI2CReceive</a>   | I2C is configured for master or slave receive mode.  |

**32.2.5.15** `static uint8_t I2C_HAL_ReadByte ( I2C_Type * base ) [inline], [static]`

In a master receive mode, calling this function initiates receiving the next byte of data.

### Parameters

---

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**Returns**

This function returns the last byte received while the I2C module is configured in master receive or slave receive mode.

**32.2.5.16 static void I2C\_HAL\_WriteByte ( I2C\_Type \* *base*, uint8\_t *byte* ) [inline], [static]**

When this function is called in the master transmit mode, a data transfer is initiated. In slave mode, the same function is available after an address match occurs.

In a master transmit mode, the first byte of data written following the start bit or repeated start bit is used for the address transfer and must consist of the slave address (in bits 7-1) concatenated with the required R/#W bit (in position bit 0).

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>base</i> | The I2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.    |

**32.2.5.17 uint8\_t I2C\_HAL\_ReadByteBlocking ( I2C\_Type \* *base* )**

It will wait till the transfer is actually completed.

**Parameters**

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**Returns**

Returns the last byte received

**32.2.5.18 bool I2C\_HAL\_WriteByteBlocking ( I2C\_Type \* *base*, uint8\_t *byte* )**

## I2C HAL driver

### Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>base</i> | The I2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.    |

### Returns

Whether ACK is received(TRUE) or not(FALSE).

### 32.2.5.19 `i2c_status_t I2C_HAL_MasterReceiveDataPolling ( I2C_Type * base, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize )`

### Parameters

|                  |                                                        |
|------------------|--------------------------------------------------------|
| <i>base</i>      | The I2C peripheral base pointer.                       |
| <i>slaveAddr</i> | The slave address to communicate.                      |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred.         |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred. |
| <i>rxBuff</i>    | The pointer to the data to be transferred.             |
| <i>rxSize</i>    | The length in bytes of the data to be transferred.     |

### Returns

Error or success status returned by API.

### 32.2.5.20 `i2c_status_t I2C_HAL_MasterSendDataPolling ( I2C_Type * base, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, const uint8_t * txBuff, uint32_t txSize )`

### Parameters

|                  |                                   |
|------------------|-----------------------------------|
| <i>base</i>      | The I2C peripheral base pointer.  |
| <i>slaveAddr</i> | The slave address to communicate. |

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>cmdBuff</i> | The pointer to the commands to be transferred.         |
| <i>cmdSize</i> | The length in bytes of the commands to be transferred. |
| <i>txBuff</i>  | The pointer to the data to be transferred.             |
| <i>txSize</i>  | The length in bytes of the data to be transferred.     |

Returns

Error or success status returned by API.

**32.2.5.21 i2c\_status\_t I2C\_HAL\_SlaveSendDataPolling ( I2C\_Type \* base, const uint8\_t \* txBuff, uint32\_t txSize )**

Parameters

|               |                                                     |
|---------------|-----------------------------------------------------|
| <i>base</i>   | I2C module base pointer.                            |
| <i>txBuff</i> | The buffer pointer which saves the data to be sent. |
| <i>txSize</i> | Size of data to be sent in unit of byte.            |

Returns

Whether the transaction is success or not.

Return values

|                                 |                                    |
|---------------------------------|------------------------------------|
| <i>kStatus_I2C_Received-Nak</i> | if received NACK bit               |
| <i>Error</i>                    | or success status returned by API. |

**32.2.5.22 i2c\_status\_t I2C\_HAL\_SlaveReceiveDataPolling ( I2C\_Type \* base, uint8\_t \* rxBuff, uint32\_t rxSize )**

Parameters

|             |                          |
|-------------|--------------------------|
| <i>base</i> | I2C module base pointer. |
|-------------|--------------------------|

## I2C HAL driver

|               |                                                         |
|---------------|---------------------------------------------------------|
| <i>rxBuff</i> | The buffer pointer which saves the data to be received. |
| <i>rxSize</i> | Size of data need to be received in unit of byte.       |

Returns

Error or success status returned by API.

### 32.2.5.23 void I2C\_HAL\_SetAddress7bit ( I2C\_Type \* *base*, uint8\_t *address* )

Parameters

|                |                                                                       |
|----------------|-----------------------------------------------------------------------|
| <i>base</i>    | The I2C peripheral base pointer                                       |
| <i>address</i> | The slave address in the upper 7 bits. Bit 0 of this value must be 0. |

### 32.2.5.24 void I2C\_HAL\_SetAddress10bit ( I2C\_Type \* *base*, uint16\_t *address* )

Parameters

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| <i>base</i>    | The I2C peripheral base pointer                                         |
| <i>address</i> | The 10-bit slave address, in bits [10:1] of the value. Bit 0 must be 0. |

### 32.2.5.25 static void I2C\_HAL\_SetExtensionAddrCmd ( I2C\_Type \* *base*, bool *enable* ) [inline], [static]

Parameters

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer                                        |
| <i>enable</i> | true: 10-bit address is enabled. false: 10-bit address is not enabled. |

### 32.2.5.26 static bool I2C\_HAL\_GetExtensionAddrCmd ( I2C\_Type \* *base* ) [inline], [static]

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

Returns

true: 10-bit address is enabled. false: 10-bit address is not enabled.

**32.2.5.27 static void I2C\_HAL\_SetGeneralCallCmd ( I2C\_Type \* *base*, bool *enable* )  
[inline], [static]**

Parameters

|               |                                             |
|---------------|---------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer             |
| <i>enable</i> | Whether to enable the general call address. |

**32.2.5.28 static void I2C\_HAL\_SetRangeMatchCmd ( I2C\_Type \* *base*, bool *enable* )  
[inline], [static]**

Parameters

|               |                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer.                                                                                                       |
| <i>enable</i> | Pass true to enable range address matching. You must also call <a href="#">I2C_HAL_SetUpperAddress7bit()</a> to set the upper address. |

**32.2.5.29 static void I2C\_HAL\_SetUpperAddress7bit ( I2C\_Type \* *base*, uint8\_t *address* )  
[inline], [static]**

This slave address is used as a secondary slave address. If range address matching is enabled, this slave address acts as the upper bound on the slave address range.

This function sets only a 7-bit slave address. If 10-bit addressing was enabled by calling [I2C\\_HAL\\_SetAddress10bit\(\)](#), then the top 3 bits set with that function are also used with the address set with this function to form a 10-bit address.

Passing 0 for the *address* parameter disables matching the upper slave address.

## I2C HAL driver

### Parameters

|                |                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>    | The I2C peripheral base pointer                                                                                                                                                                                        |
| <i>address</i> | The upper slave address in the upper 7 bits. Bit 0 of this value must be 0. In addition, this address must be greater than the primary slave address that is set by calling <a href="#">I2C_HAL_SetAddress7bit()</a> . |

### 32.2.5.30 `static bool I2C_HAL_GetStatusFlag ( I2C_Type * base, i2c_status_flag_t statusFlag ) [inline], [static]`

### Parameters

|                   |                                                                   |
|-------------------|-------------------------------------------------------------------|
| <i>base</i>       | The I2C peripheral base pointer.                                  |
| <i>statusFlag</i> | The status flag, defined in type <code>i2c_status_flag_t</code> . |

### Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

### 32.2.5.31 `static bool I2C_HAL_IsMaster ( I2C_Type * base ) [inline], [static]`

### Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>base</i> | The I2C peripheral base pointer. |
|-------------|----------------------------------|

### Returns

Whether current I2C is in master mode or not.

### Return values

|             |                                                                               |
|-------------|-------------------------------------------------------------------------------|
| <i>true</i> | The module is in master mode, which implies it is also performing a transfer. |
|-------------|-------------------------------------------------------------------------------|

|              |                              |
|--------------|------------------------------|
| <i>false</i> | The module is in slave mode. |
|--------------|------------------------------|

**32.2.5.32 static void I2C\_HAL\_ClearArbitrationLost ( I2C\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

**32.2.5.33 static void I2C\_HAL\_SetIntCmd ( I2C\_Type \* *base*, bool *enable* ) [inline], [static]**

Parameters

|               |                                                  |
|---------------|--------------------------------------------------|
| <i>base</i>   | The I2C peripheral base pointer                  |
| <i>enable</i> | Pass true to enable interrupt, false to disable. |

**32.2.5.34 static bool I2C\_HAL\_GetIntCmd ( I2C\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

Returns

Whether I2C interrupts are enabled or not.

**32.2.5.35 static bool I2C\_HAL\_IsIntPending ( I2C\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

## I2C HAL driver

### Returns

Whether I2C interrupt is pending or not.

**32.2.5.36** `static void I2C_HAL_ClearInt ( I2C_Type * base ) [inline], [static]`

### Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | The I2C peripheral base pointer |
|-------------|---------------------------------|

## 32.3 I2C Master peripheral

### 32.3.1 Overview

This section describes the programming interface of the I2C master mode Peripheral driver. The I2C master Peripheral driver provides functions for a master device to send and receive data.

### 32.3.2 I2C Initialization

To initialize the I2C driver, define an `i2c_master_state_t` type variable and pass it in the `i2c_init`. The variable does not need to have a specific value because the I2C driver only needs the memory associated with the variable. Because all I2C master API functions need the run-time structure, it should be maintained as long as the driver is used.

Because I2C drivers use the `OSA_Delay` from OSA layer, `OSA_Init` must be called before calling I2C transaction API functions. Otherwise, the API functions do not work.

### 32.3.3 I2C Data Transactions

I2C master driver provides these APIs for data transactions:

```
I2C_DRV_MasterSendDataBlocking \n
I2C_DRV_MasterReceiveDataBlocking \n
```

Both of these functions perform a blocking transaction, which means that the function does not return until all data is sent/received OR a time out occurs.

Before calling the API functions, the application should define the slave device with "i2c\_device\_t" type. Note that, if the slave is a 10-bit address, the first 6 bits must be 011110 in binary.

```
typedef struct I2CDevice
{
 uint16_t address; // Slave's 7-bit or 10-bit address. If 10-bit address, the first 6 bits must be
 // 011110 in binary.//
 uint32_t baudRate_kbps; // The baud rate in kbps to use with this slave device.//
} i2c_device_t;
```

If the `baudRate_kbps` inside the `i2c_device_t` object is changed, it is automatically applied to the next send/receive transaction.

## Data Structures

- struct `i2c_device_t`  
*Information necessary to communicate with an I2C slave device. [More...](#)*
- struct `i2c_master_state_t`  
*Internal driver state information. [More...](#)*

## I2C Master peripheral

### Variables

- I2C\_Type \*const [g\\_i2cBase](#) [I2C\_INSTANCE\_COUNT]  
*Table of base addresses for I2C instances.*

### I2C Master

- [i2c\\_status\\_t I2C\\_DRV\\_MasterInit](#) (uint32\_t instance, [i2c\\_master\\_state\\_t](#) \*master)  
*Initializes the I2C master mode driver.*

- [i2c\\_status\\_t I2C\\_DRV\\_MasterGetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Gets the current status of the I2C master receive.*
- static [i2c\\_status\\_t I2C\\_DRV\\_MasterReceiveDataPolling](#) (uint32\_t instance, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Performs a polling receive transaction on the I2C bus.*
- static [i2c\\_status\\_t I2C\\_DRV\\_MasterSendDataPolling](#) (uint32\_t instance, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, const uint8\_t \*txBuff, uint32\_t txSize)  
*Performs a polling send transaction on the I2C bus.*
- void [I2C\\_DRV\\_MasterIRQHandler](#) (uint32\_t instance)  
*The interrupt handler for I2C master mode.*

### 32.3.4 Data Structure Documentation

#### 32.3.4.1 struct i2c\_device\_t

##### Data Fields

- uint16\_t [address](#)  
*Slave's 7-bit or 10-bit address.*
- uint32\_t [baudRate\\_kbps](#)  
*The baud rate in kbps to use by current slave device.*

##### 32.3.4.1.0.132 Field Documentation

###### 32.3.4.1.0.132.1 uint16\_t i2c\_device\_t::address

If 10-bit address, the first 6 bits must be 011110 in binary.

#### 32.3.4.2 struct i2c\_master\_state\_t

Note

The contents of this structure are internal to the driver and should not be modified by users. Also, contents of the structure are subject to change in future releases.

### 32.3.5 Function Documentation

#### 32.3.5.1 i2c\_status\_t I2C\_DRV\_MasterInit ( uint32\_t *instance*, i2c\_master\_state\_t \* *master* )

Parameters

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <i>instance</i> | The I2C peripheral instance number.                   |
| <i>master</i>   | The pointer to the I2C master driver state structure. |

Returns

Error or success status returned by API.

#### 32.3.5.2 i2c\_status\_t I2C\_DRV\_MasterDeinit ( uint32\_t *instance* )

## I2C Master peripheral

### Parameters

|                 |                                     |
|-----------------|-------------------------------------|
| <i>instance</i> | The I2C peripheral instance number. |
|-----------------|-------------------------------------|

### Returns

Error or success status returned by API.

### 32.3.5.3 void I2C\_DRV\_MasterSetBaudRate ( uint32\_t *instance*, const i2c\_device\_t \* *device* )

### Parameters

|                 |                                                      |
|-----------------|------------------------------------------------------|
| <i>instance</i> | The I2C peripheral instance number.                  |
| <i>device</i>   | The pointer to the I2C device information structure. |

### 32.3.5.4 i2c\_status\_t I2C\_DRV\_MasterSendDataBlocking ( uint32\_t *instance*, const i2c\_device\_t \* *device*, const uint8\_t \* *cmdBuff*, uint32\_t *cmdSize*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout\_ms* )

Both *cmdBuff* and *txBuff* are byte aligned, user needs to prepare these buffers according to related protocol if slave devices data are not byte-aligned.

### Parameters

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <i>instance</i>   | The I2C peripheral instance number.                                |
| <i>device</i>     | The pointer to the I2C device information structure.               |
| <i>cmdBuff</i>    | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>    | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>     | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>     | The length in bytes of the data to be transferred, cannot be 0.    |
| <i>timeout_ms</i> | A timeout for the transfer in microseconds.                        |

### Returns

Error or success status returned by API.

**32.3.5.5 `i2c_status_t I2C_DRV_MasterSendData ( uint32_t instance, const i2c_device_t * device, const uint8_t * cmdBuff, uint32_t cmdSize, const uint8_t * txBuff, uint32_t txSize )`**

This function returns immediately when set buffer pointer and length to transfer buffer and transfer Size. The user must check the status of I2C to know the whether transmission is finished or not. Both cmdBuff and txBuff are byte aligned, user needs to prepare these buffers according to related protocol if slave devices data are not byte-aligned.

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The I2C peripheral instance number.                                |
| <i>device</i>   | The pointer to the I2C device information structure.               |
| <i>cmdBuff</i>  | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>  | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>   | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>   | The length in bytes of the data to be transferred, cannot be 0.    |

Returns

Error or success status returned by API.

**32.3.5.6 `i2c_status_t I2C_DRV_MasterGetSendStatus ( uint32_t instance, uint32_t * bytesRemaining )`**

This function gets the current I2C status of the non-blocking transmit.

Parameters

|                        |                                                            |
|------------------------|------------------------------------------------------------|
| <i>instance</i>        | Instance number of the I2C module.                         |
| <i>bytes-Remaining</i> | The number of remaining bytes in the active I2C transmits. |

Returns

Current status of I2C transmission: in progress (busy) or complete (success).

**32.3.5.7 `i2c_status_t I2C_DRV_MasterAbortSendData ( uint32_t instance )`**

## I2C Master peripheral

### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

### Returns

Whether the aborting is success or not.

**32.3.5.8** `i2c_status_t I2C_DRV_MasterReceiveDataBlocking ( uint32_t instance, const i2c_device_t * device, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout_ms )`

Both cmdBuff and rxBuff are byte aligned, user needs to prepare these buffers according to related protocol if slave devices data are not byte-aligned.

### Parameters

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <i>instance</i>   | The I2C peripheral instance number.                                |
| <i>device</i>     | The pointer to the I2C device information structure.               |
| <i>cmdBuff</i>    | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>    | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>     | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>     | The length in bytes of the data to be transferred, cannot be 0.    |
| <i>timeout_ms</i> | A timeout for the transfer in microseconds.                        |

### Returns

Error or success status returned by API.

**32.3.5.9** `i2c_status_t I2C_DRV_MasterReceiveData ( uint32_t instance, const i2c_device_t * device, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize )`

This function returns immediately after set buffer pointer and length to the receive buffer and the receive size. The user must check the status of I2C to know the whether the receiving is finished or not. Both cmdBuff and rxBuff are byte aligned, user needs to prepare these buffers according to related protocol if slave devices data are not byte-aligned.

### Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The I2C peripheral instance number.                                |
| <i>device</i>   | The pointer to the I2C device information structure.               |
| <i>cmdBuff</i>  | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>  | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>   | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>   | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

#### 32.3.5.10 **i2c\_status\_t I2C\_DRV\_MasterGetReceiveStatus ( uint32\_t instance, uint32\_t \* bytesRemaining )**

This function is designed to get the current I2C status of a non-blocking receive.

### Parameters

|                        |                                                            |
|------------------------|------------------------------------------------------------|
| <i>instance</i>        | Instance number of the I2C module.                         |
| <i>bytes-Remaining</i> | The number of remaining bytes in the active I2C transmits. |

### Returns

Current status of I2C receive: in progress (busy) or complete (success).

#### 32.3.5.11 **static i2c\_status\_t I2C\_DRV\_MasterReceiveDataPolling ( uint32\_t instance, uint16\_t slaveAddr, const uint8\_t \* cmdBuff, uint32\_t cmdSize, uint8\_t \* rxBuff, uint32\_t rxSize ) [inline], [static]**

Both cmdBuff and rxBuff are byte aligned. The user needs to prepare these buffers according to the related protocol if the slave device data is not byte-aligned.

### Parameters

---

## I2C Master peripheral

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>instance</i>  | Instance number of the I2C module.                                 |
| <i>slaveAddr</i> | The slave address to communicate.                                  |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>    | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>    | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

**32.3.5.12** `static i2c_status_t I2C_DRV_MasterSendDataPolling ( uint32_t instance, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, const uint8_t * txBuff, uint32_t txSize ) [inline], [static]`

Both cmdBuff and txBuff are byte aligned. The user needs to prepare these buffers according to the related protocol if the slave device data is not byte-aligned.

### Parameters

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>instance</i>  | Instance number of the I2C module.                                 |
| <i>slaveAddr</i> | The slave address to communicate.                                  |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>    | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>    | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

**32.3.5.13** `void I2C_DRV_MasterIRQHandler ( uint32_t instance )`

Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

### 32.3.6 Variable Documentation

#### 32.3.6.1 I2C\_Type\* const g\_i2cBase[I2C\_INSTANCE\_COUNT]

## I2C Slave peripheral driver

### 32.4 I2C Slave peripheral driver

#### 32.4.1 Overview

This section describes the programming interface of the I2C slave mode Peripheral driver.

#### Data Structures

- struct [i2c\\_slave\\_state\\_t](#)  
*Runtime state of the I2C Slave driver. [More...](#)*
- struct [i2c\\_slave\\_user\\_config\\_t](#)  
*Defines the structure to initialize the I2C Slave module. [More...](#)*

#### Typedefs

- typedef void(\* [i2c\\_slave\\_callback\\_t](#) )(uint8\_t instance, [i2c\\_slave\\_event\\_t](#) slaveEvent, void \*userData)  
*I2C slave callback function.*

#### Enumerations

- enum [i2c\\_slave\\_event\\_t](#) {  
[kI2CSlaveTxReq](#) = 0x02u,  
[kI2CSlaveRxReq](#) = 0x04u,  
[kI2CSlaveTxNAK](#) = 0x08u,  
[kI2CSlaveTxEmpty](#) = 0x10u,  
[kI2CSlaveRxFull](#) = 0x20u,  
[kI2CSlaveAbort](#) = 0x40u }  
*Internal driver state information.*

#### Variables

- I2C\_Type \*const [g\\_i2cBase](#) [I2C\_INSTANCE\_COUNT]  
*Table of base addresses for I2C instances.*

#### I2C Slave

- [i2c\\_status\\_t](#) [I2C\\_DRV\\_SlaveInit](#) (uint32\_t instance, const [i2c\\_slave\\_user\\_config\\_t](#) \*userConfigPtr, [i2c\\_slave\\_state\\_t](#) \*slave)  
*Initializes the I2C module.*
- [i2c\\_status\\_t](#) [I2C\\_DRV\\_SlaveDeinit](#) (uint32\_t instance)  
*Shuts down the I2C slave driver.*
- [i2c\\_slave\\_state\\_t](#) \* [I2C\\_DRV\\_SlaveGetHandler](#) (uint32\_t instance)

- Gets the I2C slave run-time state structure.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveSendData](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)  
*Sends/transmits data by using a non-blocking method.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveSendDataBlocking](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize, uint32\_t timeout\_ms)  
*Sends (transmits) data by using a blocking method.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveReceiveData](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Receives the data by using a non-blocking method.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveReceiveDataBlocking](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize, uint32\_t timeout\_ms)  
*Receives data by using a blocking method.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveGetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Gets the current status of the I2C slave driver.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveGetTransmitStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Gets the current status of the I2C slave driver.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveAbortReceiveData](#) (uint32\_t instance, uint32\_t \*rxSize)  
*Terminates a non-blocking receive of the I2C slave early.*
- [i2c\\_status\\_t I2C\\_DRV\\_SlaveAbortSendData](#) (uint32\_t instance, uint32\_t \*txSize)  
*Terminates a non-blocking send of the I2C slave early.*
- static bool [I2C\\_DRV\\_SlaveIsBusBusy](#) (uint32\_t instance)  
*Gets the current status of the I2C slave bus.*
- static [i2c\\_status\\_t I2C\\_DRV\\_SlaveSendDataPolling](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)  
*Sends out multiple bytes of data using a polling method.*
- static [i2c\\_status\\_t I2C\\_DRV\\_SlaveReceiveDataPolling](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Receives multiple bytes of data using a polling method.*
- void [I2C\\_DRV\\_SlaveIRQHandler](#) (uint32\_t instance)  
*The interrupt handler for I2C slave mode.*

### 32.4.2 Data Structure Documentation

#### 32.4.2.1 struct i2c\_slave\_state\_t

This structure holds data used by the I2C Slave Peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress.

#### Data Fields

- [i2c\\_status\\_t status](#)  
*The slave I2C status.*
- volatile uint32\_t [txSize](#)  
*Size of the TX buffer.*
- volatile uint32\_t [rxSize](#)  
*Size of the RX buffer.*
- const uint8\_t \* [txBuff](#)  
*Pointer to Tx Buffer.*

## I2C Slave peripheral driver

- `uint8_t * rxBuff`  
*Pointer to Rx Buffer.*
- `bool isTxBusy`  
*True if the driver is sending data.*
- `bool isRxBusy`  
*True if the driver is receiving data.*
- `bool isTxBlocking`  
*True if transmit is blocking transaction.*
- `bool isRxBlocking`  
*True if receive is blocking transaction.*
- `event_t irqEvent`  
*Use to wait for ISR to complete its Tx, Rx business.*
- `bool slaveListening`  
*True if slave is in listening mode.*
- `i2c_slave_callback_t slaveCallback`  
*Pointer to user callback function.*
- `void * callbackParam`  
*Pointer to user callback param.*

**32.4.2.1.0.133.4** `const uint8_t* i2c_slave_state_t::txBuff`

**32.4.2.1.0.133.5** `uint8_t* i2c_slave_state_t::rxBuff`

**32.4.2.1.0.133.6** `bool i2c_slave_state_t::isTxBusy`

**32.4.2.1.0.133.7** `bool i2c_slave_state_t::isRxBusy`

**32.4.2.1.0.133.8** `bool i2c_slave_state_t::isTxBlocking`

**32.4.2.1.0.133.9** `bool i2c_slave_state_t::isRxBlocking`

**32.4.2.1.0.133.10** `bool i2c_slave_state_t::slaveListening`

**32.4.2.1.0.133.11** `i2c_slave_callback_t i2c_slave_state_t::slaveCallback`

**32.4.2.1.0.133.12** `void* i2c_slave_state_t::callbackParam`

**32.4.2.2** `struct i2c_slave_user_config_t`

### Note

once slaveListening mode is selected, all send/receive blocking/non-blocking functions will be invalid.

### Data Fields

- uint16\_t **address**  
*Slave's 7-bit or 10-bit address.*
- bool **slaveListening**  
*The slave configuration mode.*
- i2c\_slave\_callback\_t **slaveCallback**  
*The slave callback function.*
- void \* **callbackParam**  
*The slave callback data.*

#### 32.4.2.2.0.134 Field Documentation

##### 32.4.2.2.0.134.1 uint16\_t i2c\_slave\_user\_config\_t::address

If 10-bit address, the first 6 bits must be 011110 in binary.

### 32.4.3 Enumeration Type Documentation

#### 32.4.3.1 enum i2c\_slave\_event\_t

### Note

The contents of this structure are internal to the driver and should not be modified by users. Also, contents of the structure are subject to change in future releases.

Defines the type of flags for callback function

### Enumerator

- kI2CSlaveTxReq*** The slave I2C Transmitting Request event.
- kI2CSlaveRxReq*** The slave I2C Receiving Request event.
- kI2CSlaveTxNAK*** The slave I2C Transmitting NAK event.
- kI2CSlaveTxEmpty*** The slave I2C Transmitting Buffer Empty event.
- kI2CSlaveRxFull*** The slave I2C Receiving Buffer Full event.
- kI2CSlaveAbort*** The slave I2C Slave abort transaction event.

## I2C Slave peripheral driver

### 32.4.4 Function Documentation

#### 32.4.4.1 `i2c_status_t I2C_DRV_Slavelnit ( uint32_t instance, const i2c_slave_user_config_t * userConfigPtr, i2c_slave_state_t * slave )`

Saves the application callback info, turns on the clock to the module, enables the device, and enables interrupts. Sets the I2C to slave mode. IOMUX should be handled in the `init_hardware()` function.

### Parameters

|                      |                                             |
|----------------------|---------------------------------------------|
| <i>instance</i>      | Instance number of the I2C module.          |
| <i>userConfigPtr</i> | Pointer of the user configuration structure |
| <i>slave</i>         | Pointer of the slave run-time structure.    |

### Returns

Error or success status returned by API.

#### 32.4.4.2 `i2c_status_t I2C_DRV_SlaveDeinit ( uint32_t instance )`

Clears the control register and turns off the clock to the module.

### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

### Returns

Error or success status returned by API.

#### 32.4.4.3 `i2c_slave_state_t* I2C_DRV_SlaveGetHandler ( uint32_t instance )`

This function gets the I2C slave run-time state structure.

### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

### Returns

Pointer to I2C slave run-time state structure.

#### 32.4.4.4 `i2c_status_t I2C_DRV_SlaveSendData ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize )`

This function returns immediately when the buffer pointer and length are set to the transfer buffer and transfer size. The user should check the status of I2C slave to find out whether the transmission is completed. The user can also wait the `kI2CSlaveStop` or the `kI2CSlaveTxDone` to ensure that the transmission is ended.

## I2C Slave peripheral driver

### Parameters

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.                |
| <i>txBuff</i>   | The pointer to sending the data buffer.           |
| <i>txSize</i>   | The number of bytes which the user wants to send. |

### Returns

success (if I2C slave status is not error) or error code in others.

#### 32.4.4.5 **i2c\_status\_t I2C\_DRV\_SlaveSendDataBlocking ( uint32\_t instance, const uint8\_t \* txBuff, uint32\_t txSize, uint32\_t timeout\_ms )**

This function sets the buffer pointer and length to the transfer buffer and the transfer size and waits until the transmission is ended (NAK is detected).

### Parameters

|                   |                                                                   |
|-------------------|-------------------------------------------------------------------|
| <i>instance</i>   | Instance number of the I2C module.                                |
| <i>txBuff</i>     | The pointer to sending the data buffer.                           |
| <i>txSize</i>     | The number of bytes which the user wants to send.                 |
| <i>timeout_ms</i> | The maximum number of milliseconds to wait for transmit completed |

### Returns

success (if I2C slave status is not error) or error code in others.

#### 32.4.4.6 **i2c\_status\_t I2C\_DRV\_SlaveReceiveData ( uint32\_t instance, uint8\_t \* rxBuff, uint32\_t rxSize )**

This function returns immediately when the buffer pointer and length are set to the receive buffer and the receive size. The user should check the status of the I2C slave to find out whether the transmission is completed. The user can also wait the `kI2CSlaveStop` or the `kI2CSlaveRxDone` to ensure that the transmission is ended.

### Parameters

|                 |                                                      |
|-----------------|------------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.                   |
| <i>rxBuff</i>   | The pointer to the received data buffer.             |
| <i>rxSize</i>   | The number of bytes which the user wants to receive. |

Returns

success (if I2C slave status is not error) or error code in others.

### 32.4.4.7 **i2c\_status\_t I2C\_DRV\_SlaveReceiveDataBlocking ( uint32\_t *instance*, uint8\_t \* *rxBuff*, uint32\_t *rxSize*, uint32\_t *timeout\_ms* )**

This function sets the buffer pointer and length to the receive buffer and the receive size. Then, the function waits until the transmission is ended (all data is received or a STOP signal is detected).

Parameters

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| <i>instance</i>   | Instance number of the I2C module.                               |
| <i>rxBuff</i>     | The pointer to the received data buffer.                         |
| <i>rxSize</i>     | The number of bytes which the user wants to receive.             |
| <i>timeout_ms</i> | The maximum number of milliseconds to wait for receive completed |

Returns

success (if I2C slave status is not error) or error code in others.

### 32.4.4.8 **i2c\_status\_t I2C\_DRV\_SlaveGetReceiveStatus ( uint32\_t *instance*, uint32\_t \* *bytesRemaining* )**

Parameters

|                        |                                                   |
|------------------------|---------------------------------------------------|
| <i>instance</i>        | Instance number of the I2C module.                |
| <i>bytes-Remaining</i> | The number of remaining bytes that I2C transmits. |

## I2C Slave peripheral driver

Returns

The current status of I2C instance: in progress (busy), complete (success) or idle (I2C bus is idle).

### 32.4.4.9 `i2c_status_t I2C_DRV_SlaveGetTransmitStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                   |
|------------------------|---------------------------------------------------|
| <i>instance</i>        | Instance number of the I2C module.                |
| <i>bytes-Remaining</i> | The number of remaining bytes that I2C transmits. |

Returns

The current status of I2C instance: in progress (busy), complete (success) or idle (I2C bus is idle).

### 32.4.4.10 `i2c_status_t I2C_DRV_SlaveAbortReceiveData ( uint32_t instance, uint32_t * rxSize )`

During an non-blocking receiving

Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.              |
| <i>rxSize</i>   | The number of remaining bytes in I2C Rx Buffer. |

Returns

`kStatus_I2C_Success` if success `kStatus_I2C_NoReceiveInProgress` if none receiving is available.

### 32.4.4.11 `i2c_status_t I2C_DRV_SlaveAbortSendData ( uint32_t instance, uint32_t * txSize )`

During an non-blocking receiving

### Parameters

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.              |
| <i>txSize</i>   | The number of remaining bytes in I2C Tx Buffer. |

### Returns

kStatus\_I2C\_Success if success kStatus\_I2C\_NoReceiveInProgress if none receiving is available.

#### 32.4.4.12 **static bool I2C\_DRV\_SlavelBusBusy ( uint32\_t *instance* ) [inline], [static]**

### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

### Returns

True if the bus is busy False if the bus is idle

#### 32.4.4.13 **static i2c\_status\_t I2C\_DRV\_SlaveSendDataPolling ( uint32\_t *instance*, const uint8\_t \* *txBuff*, uint32\_t *txSize* ) [inline], [static]**

### Parameters

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.                  |
| <i>txBuff</i>   | The buffer pointer which saves the data to be sent. |
| <i>txSize</i>   | Size of data to be sent in bytes.                   |

### Returns

Error or success status returned by API.

#### 32.4.4.14 **static i2c\_status\_t I2C\_DRV\_SlaveReceiveDataPolling ( uint32\_t *instance*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* ) [inline], [static]**

## I2C Slave peripheral driver

### Parameters

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <i>instance</i> | Instance number of the I2C module.                      |
| <i>rxBuff</i>   | The buffer pointer which saves the data to be received. |
| <i>rxSize</i>   | Size of data need to be received in bytes.              |

### Returns

Error or success status returned by the API.

### 32.4.4.15 void I2C\_DRV\_SlaveIRQHandler ( uint32\_t *instance* )

#### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>instance</i> | Instance number of the I2C module. |
|-----------------|------------------------------------|

## 32.4.5 Variable Documentation

### 32.4.5.1 I2C\_Type\* const g\_i2cBase[I2C\_INSTANCE\_COUNT]

## Chapter 33

# Interrupt Manager (Interrupt)

The Kinetis SDK Interrupt Manager provides a set of API/services to configure the Interrupt Controller (NVIC).

### 33.1 Overview

#### Files

- file [fsl\\_interrupt\\_manager.h](#)

#### Enumerations

- enum [interrupt\\_status\\_t](#)  
*interrupt status return codes.*

#### interrupt\_manager APIs

- void \* [INT\\_SYS\\_InstallHandler](#) (IRQn\_Type irqNumber, void(\*handler)(void))  
*Installs an interrupt handler routine for a given IRQ number.*
- static void [INT\\_SYS\\_EnableIRQ](#) (IRQn\_Type irqNumber)  
*Enables an interrupt for a given IRQ number.*
- static void [INT\\_SYS\\_DisableIRQ](#) (IRQn\_Type irqNumber)  
*Disables an interrupt for a given IRQ number.*
- void [INT\\_SYS\\_EnableIRQGlobal](#) (void)  
*Enables system interrupt.*
- void [INT\\_SYS\\_DisableIRQGlobal](#) (void)  
*Disable system interrupt.*

#### 33.1.1 Interrupt Manager

##### Overview

The Interrupt Manager provides a set of APIs so that the application can enable or disable an interrupt for a specific device and also set/get interrupt status, priority, and other features. Additionally, it provides a way to update the vector table for a specific device interrupt handler.

##### Interrupt Names

Each chip has its own set of supported interrupt names defined in the chip-specific header file. For example, for K70, the header file is MK70F12.h or MK70F15.h as an IRQn\_Type.

This is an example to set/update the vector table for the I2C0\_IRQn interrupt handler:

## Function Documentation

```
#include "interrupt/fsl_interrupt_manager.h"

interrupt_register_handler(I2C0_IRQn, irq_handler_I2C0_IRQn);
```

This is an example to enable/disable an interrupt for the I2C0\_IRQn:

```
#include "interrupt/fsl_interrupt_manager.h"

interrupt_enable(I2C0_IRQn);

interrupt_disable(I2C0_IRQn);
```

## 33.2 Enumeration Type Documentation

### 33.2.1 enum interrupt\_status\_t

## 33.3 Function Documentation

### 33.3.1 void\* INT\_SYS\_InstallHandler ( IRQn\_Type irqNumber, void(\*)(void) handler )

This function lets the application register/replace the interrupt handler for a specified IRQ number. The IRQ number is different than the vector number. IRQ 0 starts from the vector 16 address. See a chip-specific reference manual for details and the startup\_MKxxxx.s file for each chip family to find out the default interrupt handler for each device. This function converts the IRQ number to the vector number by adding 16 to it.

Parameters

|                  |                                           |
|------------------|-------------------------------------------|
| <i>irqNumber</i> | IRQ number                                |
| <i>handler</i>   | Interrupt handler routine address pointer |

Returns

Whether the installation succeed or not

### 33.3.2 static void INT\_SYS\_EnableIRQ ( IRQn\_Type irqNumber ) [inline], [static]

This function enables the individual interrupt for a specified IRQ number. It calls the system NVIC API to access the interrupt control register. The input IRQ number does not include the core interrupt, only the peripheral interrupt, from 0 to a maximum supported IRQ.

Parameters

|                  |            |
|------------------|------------|
| <i>irqNumber</i> | IRQ number |
|------------------|------------|

**33.3.3 static void INT\_SYS\_DisableIRQ ( IRQn\_Type *irqNumber* ) [inline], [static]**

This function enables the individual interrupt for a specified IRQ number. It calls the system NVIC API to access the interrupt control register.

Parameters

|                  |            |
|------------------|------------|
| <i>irqNumber</i> | IRQ number |
|------------------|------------|

**33.3.4 void INT\_SYS\_EnableIRQGlobal ( void )**

This function enables the global interrupt by calling the core API.

**33.3.5 void INT\_SYS\_DisableIRQGlobal ( void )**

This function disables the global interrupt by calling the core API.

## Chapter 34

# Independent Real Time Clock (IRTC)

### 34.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Independent Real Time Clock (IRTC) block of Kinetis devices.

#### Modules

- [IRTC HAL driver](#)
- [IRTC Peripheral Driver](#)

## IRTC HAL driver

### 34.2 IRTC HAL driver

#### 34.2.1 Overview

This section describes the programming interface of the IRTC HAL driver. The IRTC HAL driver initializes the IRTC registers and provides functions to read or modify the IRTC registers. These are mostly invoked by the IRTC Peripheral driver.

#### 34.2.2 IRTC Initialization

This function initiates a soft-reset of the IRTC module to reset the IRTC registers and configure IRTC according to user settings. It doesn't un-gate the IRTC clock.

#### 34.2.3 IRTC Setting and reading the IRTC time

The HAL driver provides [IRTC\\_HAL\\_SetDatetime\(\)](#) and [IRTC\\_HAL\\_GetDatetime\(\)](#) functions to set and read the date and time using an instantiation of the [irtc\\_datetime\\_t](#) structure. This example describes the structure:

```
typedef struct IrctDatetime
{
 uint16_t year;
 uint16_t month;
 uint16_t day;
 uint16_t weekDay;
```

#### 34.2.4 IRTC Setting and reading the Alarm

The HAL driver provides [IRTC\\_HAL\\_SetAlarm\(\)](#) and [IRTC\\_HAL\\_GetAlarm\(\)](#) functions to set an alarm and read back the alarm time.

### Files

- file [fsl\\_irtc\\_hal.h](#)

### Data Structures

- struct [irtc\\_datetime\\_t](#)  
*Structure is used to hold the time in a simple "date" format. [More...](#)*
- struct [irtc\\_daylight\\_time\\_t](#)  
*Structure is used to hold the daylight saving time. [More...](#)*
- struct [irtc\\_tamper\\_config\\_t](#)  
*Structure is used to define the parameters to configure a RTC tamper event. [More...](#)*

## Enumerations

- enum `irtc_status_t`  
*Error codes for the IRTC driver.*
- enum `irtc_filter_clock_source_t` {  
`kIRTC32K` = 0x0,  
`kIRTC512` = 0x1,  
`kIRTC128` = 0x2,  
`kIRTC64` = 0x3,  
`kIRTC16` = 0x4,  
`kIRTC8` = 0x5,  
`kIRTC4` = 0x6,  
`kIRTC2` = 0x7 }  
*IRTC filter clock source options.*
- enum `irtc_tamper_pins_t` {  
`kIRTCtamper0` = 0x0,  
`kIRTCtamper1` = 0x1,  
`kIRTCtamper2` = 0x2,  
`kIRTCtamper3` = 0x3 }  
*IRTC Tamper pins.*
- enum `irtc_clock_output_t` {  
`kIRTCNoOutputClk` = 0x0,  
`kIRTCFine1hzClk` = 0x1,  
`kIRTC32khzClk` = 0x2,  
`kIRTCCoarse1hzClk` = 0x3 }  
*IRTC clock output selection.*
- enum `irtc_alarm_match_t` {  
`kIRTCSecMinHour` = 0x0,  
`kIRTCSecMinHourDay` = 0x1,  
`kIRTCSecMinHourDayMon` = 0x2,  
`kIRTCSecMinHourDayMonYear` = 0x3 }  
*IRTC alarm match selection.*
- enum `irtc_status_flag_t`  
*IRTC status flags.*
- enum `irtc_int_status_flag_t`  
*IRTC interrupt status flags.*
- enum `irtc_int_t`  
*IRTC interrupts.*

## Initialization

- void `IRTC_HAL_Init` (RTC\_Type \*base)  
*Resets the IRTC module.*
- void `IRTC_HAL_SetLockRegisterCmd` (RTC\_Type \*base, bool lock)  
*Locks or unlocks IRTC registers for write access.*

## IRTC HAL driver

### Date and Time Setting

#### Note

All Date and Time settings APIs except the `IRTC_HAL_SetDatetime` and the `IRTC_HAL_GetDatetime` settings, should first determine the state of the `INVAL` bit in the `STATUS`(bit 0) to determine that the counters are stable before their value can be read or changed (this be done by calling `IRTC_HAL_GetStatusFlag(base, kIRTCInvalidate)`). The assertion of `INVAL` bit ensures that no operation is done at the boundary of a second when counters change value.

- void `IRTC_HAL_SetYearMonth` (`RTC_Type *base, uint16_t year, uint16_t month`)  
*Sets the IRTC year and month.*
- void `IRTC_HAL_GetYearMonth` (`RTC_Type *base, uint16_t *year, uint16_t *month`)  
*Gets the IRTC current year and month.*
- static void `IRTC_HAL_SetDayWeek` (`RTC_Type *base, uint16_t day, uint16_t weekDay`)  
*Sets the IRTC day and day of week.*
- void `IRTC_HAL_GetDayWeek` (`RTC_Type *base, uint16_t *day, uint16_t *weekDay`)  
*Gets the IRTC current day and day of week.*
- static void `IRTC_HAL_SetHourMin` (`RTC_Type *base, uint16_t hour, uint16_t min`)  
*Sets the IRTC hours and minutes.*
- void `IRTC_HAL_GetHourMin` (`RTC_Type *base, uint16_t *hour, uint16_t *min`)  
*Gets the IRTC current hours and minutes.*
- static void `IRTC_HAL_SetSec` (`RTC_Type *base, uint16_t sec`)  
*Sets the IRTC second counter.*
- static void `IRTC_HAL_GetSec` (`RTC_Type *base, uint16_t *sec`)  
*Gets the IRTC current second counter.*
- void `IRTC_HAL_SetDatetime` (`RTC_Type *base, const irtc_datetime_t *datetime`)  
*Sets the IRTC date and time according to the given time structure.*
- void `IRTC_HAL_GetDatetime` (`RTC_Type *base, irtc_datetime_t *datetime`)  
*Gets the IRTC time and stores it in the given time structure.*

### Alarm Time Setting

- static void `IRTC_HAL_SetAlarmMatchMode` (`RTC_Type *base, irtc_alarm_match_t alarmType`)  
*Sets the alarm match type.*
- void `IRTC_HAL_SetAlarm` (`RTC_Type *base, const irtc_datetime_t *datetime`)  
*Sets the IRTC alarm time and enables the alarm interrupt.*
- void `IRTC_HAL_GetAlarm` (`RTC_Type *base, irtc_datetime_t *datetime`)  
*Reads the value of the time alarm.*

### Daylight Saving Time Setting

- static void `IRTC_HAL_SetDaylightMonth` (`RTC_Type *base, uint16_t startMonth, uint16_t endMonth`)  
*Sets IRTC daylight savings start month and end month.*
- void `IRTC_HAL_GetDaylightMonth` (`RTC_Type *base, uint16_t *startMonth, uint16_t *endMonth`)

- *Gets the IRTC current daylight savings start and end month.*
- static void [IRTC\\_HAL\\_SetDaylightDay](#) (RTC\_Type \*base, uint16\_t startDay, uint16\_t endDay)  
*Sets the IRTC daylight savings start and end day.*
- void [IRTC\\_HAL\\_GetDaylightDay](#) (RTC\_Type \*base, uint16\_t \*startDay, uint16\_t \*endDay)  
*Gets the IRTC current daylight savings start and end day.*
- static void [IRTC\\_HAL\\_SetDaylightHour](#) (RTC\_Type \*base, uint16\_t startHour, uint16\_t endHour)  
*Sets the IRTC current daylight savings start and end hour.*
- void [IRTC\\_HAL\\_GetDaylightHour](#) (RTC\_Type \*base, uint16\_t \*startHour, uint16\_t \*endHour)  
*Gets the IRTC current daylight savings start and end hour.*
- void [IRTC\\_HAL\\_SetDaylightTime](#) (RTC\_Type \*base, const [irtc\\_daylight\\_time\\_t](#) \*datetime)  
*Sets the IRTC daylight savings date and time.*
- void [IRTC\\_HAL\\_GetDaylightTime](#) (RTC\_Type \*base, [irtc\\_daylight\\_time\\_t](#) \*datetime)  
*Gets the IRTC daylight savings time and stores it in the given time structure.*

## Status

- static bool [IRTC\\_HAL\\_GetStatusFlag](#) (RTC\_Type \*base, [irtc\\_status\\_flag\\_t](#) statusFlag)  
*Gets the IRTC status flag state.*

## Interrupts

- static void [IRTC\\_HAL\\_SetIntCmd](#) (RTC\_Type \*base, [irtc\\_int\\_t](#) interrupt, bool enable)  
*Enables or disables the related IRTC interrupt.*
- static bool [IRTC\\_HAL\\_GetIntCmd](#) (RTC\_Type \*base, [irtc\\_int\\_t](#) interrupt)  
*Indicates whether the IRTC interrupt is enabled or not.*
- static bool [IRTC\\_HAL\\_GetIntStatusFlag](#) (RTC\_Type \*base, [irtc\\_int\\_status\\_flag\\_t](#) statusFlag)  
*Gets the IRTC interrupt status flag state.*
- static void [IRTC\\_HAL\\_ClearIntStatusFlag](#) (RTC\_Type \*base, [irtc\\_int\\_status\\_flag\\_t](#) statusFlag)  
*Clears the IRTC interrupt status flag.*

## IRTC Time Compensation

- void [IRTC\\_HAL\\_SetCoarseCompensation](#) (RTC\_Type \*base, uint8\_t compVal, uint8\_t compInterval)  
*Enables the coarse compensation and sets the value to the IRTC compensation register.*
- void [IRTC\\_HAL\\_SetFineCompensation](#) (RTC\_Type \*base, uint8\_t integralVal, uint8\_t fracVal, bool accumulateFrac)  
*Enables the fine compensation and sets the value to the IRTC compensation register.*

## IRTC Control

- static void [IRTC\\_HAL\\_SetClockOutMode](#) (RTC\_Type \*base, [irtc\\_clock\\_output\\_t](#) clock)  
*Selects which clock to output from the SoC for use outside the RTC.*
- static void [IRTC\\_HAL\\_SoftwareReset](#) (RTC\_Type \*base)  
*Performs a software reset on the IRTC module.*

## IRTC HAL driver

### IRTC Tamper

- void [IRTC\\_HAL\\_ConfigTamperParams](#) (RTC\_Type \*base, [irtc\\_tamper\\_pins\\_t](#) tamperNum, [irtc\\_tamper\\_config\\_t](#) \*tamperConfig)  
*This function allows configuring the four tamper inputs.*
- static void [IRTC\\_HAL\\_EnableTamper](#) (RTC\_Type \*base)  
*Enables the tamper feature.*
- static void [IRTC\\_HAL\\_DisableTamper](#) (RTC\_Type \*base)  
*Disables the tamper feature.*

## 34.2.5 Data Structure Documentation

### 34.2.5.1 struct irtc\_datetime\_t

#### Data Fields

- [uint16\\_t year](#)  
*Range from 1984 to 2239.*
- [uint16\\_t month](#)  
*Range from 1 to 12.*
- [uint16\\_t day](#)  
*Range from 1 to 31 (depending on month).*
- [uint16\\_t weekDay](#)  
*Range from 0(Sunday) to 6(Saturday).*
- [uint16\\_t hour](#)  
*Range from 0 to 23.*
- [uint16\\_t minute](#)  
*Range from 0 to 59.*
- [uint16\\_t second](#)  
*Range from 0 to 59.*

### 34.2.5.2 struct irtc\_daylight\_time\_t

#### Data Fields

- [uint16\\_t startMonth](#)  
*Range from 1 to 12.*
- [uint16\\_t endMonth](#)  
*Range from 1 to 12.*
- [uint16\\_t startDay](#)  
*Range from 1 to 31 (depending on month).*
- [uint16\\_t endDay](#)  
*Range from 1 to 31 (depending on month).*
- [uint16\\_t startHour](#)  
*Range from 0 to 23.*
- [uint16\\_t endHour](#)  
*Range from 0 to 23.*

### 34.2.5.3 struct irtc\_tamper\_config\_t

#### Data Fields

- bool `pinPolarity`  
*true: tamper has active low polarity; false: active high polarity*
- `irtc_filter_clock_source_t` `filterClk`  
*Clock source for the tamper filter.*
- `uint8_t` `filterDuration`  
*Tamper filter duration.*

#### 34.2.5.3.0.135 Field Documentation

##### 34.2.5.3.0.135.1 `uint8_t irtc_tamper_config_t::filterDuration`

### 34.2.6 Enumeration Type Documentation

#### 34.2.6.1 enum irtc\_status\_t

#### 34.2.6.2 enum irtc\_filter\_clock\_source\_t

Enumerator

- kIRTC32K*** Use 32 kHz clock source for the tamper filter.
- kIRTC512*** Use 512 Hz clock source for the tamper filter.
- kIRTC128*** Use 128 Hz clock source for the tamper filter.
- kIRTC64*** Use 64 Hz clock source for the tamper filter.
- kIRTC16*** Use 16 Hz clock source for the tamper filter.
- kIRTC8*** Use 8 Hz clock source for the tamper filter.
- kIRTC4*** Use 4 Hz clock source for the tamper filter.
- kIRTC2*** Use 2 Hz clock source for the tamper filter.

#### 34.2.6.3 enum irtc\_tamper\_pins\_t

Enumerator

- kIRCTamper0*** External Tamper 0.
- kIRCTamper1*** External Tamper 1.
- kIRCTamper2*** External Tamper 2.
- kIRCTamper3*** Internal tamper, does not have filter configuration.

#### 34.2.6.4 enum irtc\_clock\_output\_t

Enumerator

- kIRTCNoOutputClk*** No output clock.

## IRTC HAL driver

*kIRTCFine1hzClk* Fine 1 Hz clock.  
*kIRTC32khzClk* 32.768 kHz clock  
*kIRTCCoarse1hzClk* Coarse 1Hz clock.

### 34.2.6.5 enum irtc\_alarm\_match\_t

Enumerator

*kIRTCSecMinHour* Generate alarm when sec/min/hour are matched.  
*kIRTCSecMinHourDay* Generate alarm when sec/min/hour/day are matched.  
*kIRTCSecMinHourDayMon* Generate alarm when sec/min/hour/day/month are matched.  
*kIRTCSecMinHourDayMonYear* Generate alarm when sec/min/hour/day/month/year are matched.

### 34.2.6.6 enum irtc\_status\_flag\_t

### 34.2.6.7 enum irtc\_int\_status\_flag\_t

### 34.2.6.8 enum irtc\_int\_t

## 34.2.7 Function Documentation

### 34.2.7.1 void IRTC\_HAL\_Init ( RTC\_Type \* *base* )

This function initiates a soft-reset of the IRTC module to reset the IRTC registers.

Parameters

|             |                                |
|-------------|--------------------------------|
| <i>base</i> | The IRTC base address pointer. |
|-------------|--------------------------------|

### 34.2.7.2 void IRTC\_HAL\_SetLockRegisterCmd ( RTC\_Type \* *base*, bool *lock* )

Note

When the registers are unlocked, they remain in unlocked state for 2 seconds, after which they are locked automatically. After power-on-reset, the registers come out unlocked and they are locked automatically 15 seconds after power on.

Parameters

|             |                                             |
|-------------|---------------------------------------------|
| <i>base</i> | The IRTC base address pointer.              |
| <i>lock</i> | Lock(true) or unlock(false) IRTC registers. |

**34.2.7.3 void IRTC\_HAL\_SetYearMonth ( RTC\_Type \* *base*, uint16\_t *year*, uint16\_t *month* )**

Parameters

|              |                                |
|--------------|--------------------------------|
| <i>base</i>  | The IRTC base address pointer  |
| <i>year</i>  | Year number from 1984 to 2239. |
| <i>month</i> | Month number from 1 to 12.     |

**34.2.7.4 void IRTC\_HAL\_GetYearMonth ( RTC\_Type \* *base*, uint16\_t \* *year*, uint16\_t \* *month* )**

Parameters

|              |                                        |
|--------------|----------------------------------------|
| <i>base</i>  | The IRTC base address pointer          |
| <i>year</i>  | Current year number from 1984 to 2239. |
| <i>month</i> | Current month number from 1 to 12.     |

**34.2.7.5 static void IRTC\_HAL\_SetDayWeek ( RTC\_Type \* *base*, uint16\_t *day*, uint16\_t *weekDay* ) [inline], [static]**

Parameters

|                |                                                   |
|----------------|---------------------------------------------------|
| <i>base</i>    | The IRTC base address pointer                     |
| <i>day</i>     | Day number from 1 to 31.                          |
| <i>weekDay</i> | Day of week number from 0(Sunday) to 6(Saturday). |

**34.2.7.6 void IRTC\_HAL\_GetDayWeek ( RTC\_Type \* *base*, uint16\_t \* *day*, uint16\_t \* *weekDay* )**

## IRTC HAL driver

### Parameters

|                |                                                           |
|----------------|-----------------------------------------------------------|
| <i>base</i>    | The IRTC base address pointer                             |
| <i>day</i>     | Current day number from 1 to 31.                          |
| <i>weekDay</i> | Current day of week number from 0(Sunday) to 6(Saturday). |

**34.2.7.7** `static void IRTC_HAL_SetHourMin ( RTC_Type * base, uint16_t hour, uint16_t min ) [inline], [static]`

### Parameters

|             |                               |
|-------------|-------------------------------|
| <i>base</i> | The IRTC base address pointer |
| <i>hour</i> | Hour number from 0 to 23.     |
| <i>min</i>  | Min number from 0 to 59.      |

**34.2.7.8** `void IRTC_HAL_GetHourMin ( RTC_Type * base, uint16_t * hour, uint16_t * min )`

### Parameters

|             |                                     |
|-------------|-------------------------------------|
| <i>base</i> | The IRTC base address pointer       |
| <i>hour</i> | Current hour number from 0 to 23.   |
| <i>min</i>  | Current minute number from 0 to 59. |

**34.2.7.9** `static void IRTC_HAL_SetSec ( RTC_Type * base, uint16_t sec ) [inline], [static]`

### Parameters

|             |                               |
|-------------|-------------------------------|
| <i>base</i> | The IRTC base address pointer |
| <i>sec</i>  | Second number from 0 to 59.   |

**34.2.7.10** `static void IRTC_HAL_GetSec ( RTC_Type * base, uint16_t * sec ) [inline], [static]`

Parameters

|             |                                     |
|-------------|-------------------------------------|
| <i>base</i> | The IRTC base address pointer       |
| <i>sec</i>  | Current second number from 0 to 59. |

**34.2.7.11 void IRTC\_HAL\_SetDatetime ( RTC\_Type \* *base*, const irtc\_datetime\_t \* *datetime* )**

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                      |
| <i>datetime</i> | Pointer to a structure where the date and time details are stored. |

**34.2.7.12 void IRTC\_HAL\_GetDatetime ( RTC\_Type \* *base*, irtc\_datetime\_t \* *datetime* )**

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                      |
| <i>datetime</i> | Pointer to a structure where the date and time details are stored. |

**34.2.7.13 static void IRTC\_HAL\_SetAlarmMatchMode ( RTC\_Type \* *base*, irtc\_alarm\_match\_t *alarmType* ) [inline], [static]**

Parameters

|                  |                                                    |
|------------------|----------------------------------------------------|
| <i>base</i>      | The IRTC base address pointer                      |
| <i>alarmType</i> | Alarm match selections that when an alarm happens. |

**34.2.7.14 void IRTC\_HAL\_SetAlarm ( RTC\_Type \* *base*, const irtc\_datetime\_t \* *datetime* )**

The function checks whether the specified alarm time is greater than the present time. If not, the function does not set the alarm and returns an error.

## IRTC HAL driver

### Parameters

|                 |                                                                               |
|-----------------|-------------------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer.                                                |
| <i>datetime</i> | Pointer to structure where the alarm date and time details will be stored at. |

### 34.2.7.15 void IRTC\_HAL\_GetAlarm ( RTC\_Type \* *base*, irtc\_datetime\_t \* *datetime* )

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                           |
| <i>datetime</i> | Pointer to a variable where the alarm date and time details are stored. |

### 34.2.7.16 static void IRTC\_HAL\_SetDaylightMonth ( RTC\_Type \* *base*, uint16\_t *startMonth*, uint16\_t *endMonth* ) [inline],[static]

### Parameters

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <i>base</i>       | The IRTC base address pointer                    |
| <i>startMonth</i> | Daylight saving start month number from 1 to 12. |
| <i>endMonth</i>   | Daylight saving end month number from 1 to 12.   |

### 34.2.7.17 void IRTC\_HAL\_GetDaylightMonth ( RTC\_Type \* *base*, uint16\_t \* *startMonth*, uint16\_t \* *endMonth* )

### Parameters

|                   |                                                          |
|-------------------|----------------------------------------------------------|
| <i>base</i>       | The IRTC base address pointer                            |
| <i>startMonth</i> | Current daylight saving start month number from 1 to 12. |
| <i>endMonth</i>   | Current daylight saving end month number from 1 to 12.   |

### 34.2.7.18 static void IRTC\_HAL\_SetDaylightDay ( RTC\_Type \* *base*, uint16\_t *startDay*, uint16\_t *endDay* ) [inline],[static]

## Parameters

|                 |                                                      |
|-----------------|------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                        |
| <i>startDay</i> | Daylight saving day start value number from 1 to 31. |
| <i>endDay</i>   | Daylight saving day end value number from 1 to 31.   |

**34.2.7.19 void IRTC\_HAL\_GetDaylightDay ( RTC\_Type \* *base*, uint16\_t \* *startDay*, uint16\_t \* *endDay* )**

## Parameters

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                |
| <i>startDay</i> | Current daylight saving day start value number from 1 to 31. |
| <i>endDay</i>   | Current daylight saving day end value number from 1 to 31.   |

**34.2.7.20 static void IRTC\_HAL\_SetDaylightHour ( RTC\_Type \* *base*, uint16\_t *startHour*, uint16\_t *endHour* ) [inline], [static]**

## Parameters

|                  |                                   |
|------------------|-----------------------------------|
| <i>base</i>      | The IRTC base address pointer     |
| <i>startHour</i> | Daylight saving hour start value. |
| <i>endHour</i>   | Daylight saving hour end value.   |

**34.2.7.21 void IRTC\_HAL\_GetDaylightHour ( RTC\_Type \* *base*, uint16\_t \* *startHour*, uint16\_t \* *endHour* )**

## Parameters

|                  |                                           |
|------------------|-------------------------------------------|
| <i>base</i>      | The IRTC base address pointer             |
| <i>startHour</i> | Current daylight saving hour start value. |
| <i>endHour</i>   | Current daylight saving hour end value.   |

## IRTC HAL driver

**34.2.7.22 void IRTC\_HAL\_SetDaylightTime ( RTC\_Type \* *base*, const irtc\_daylight\_time\_t \* *datetime* )**

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                      |
| <i>datetime</i> | Pointer to a structure where the date and time details are stored. |

**34.2.7.23 void IRTC\_HAL\_GetDaylightTime ( RTC\_Type \* *base*, irtc\_daylight\_time\_t \* *datetime* )**

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>base</i>     | The IRTC base address pointer                                      |
| <i>datetime</i> | Pointer to a structure where the date and time details are stored. |

**34.2.7.24 static bool IRTC\_HAL\_GetStatusFlag ( RTC\_Type \* *base*, irtc\_status\_flag\_t *statusFlag* ) [inline], [static]**

Parameters

|                   |                                                      |
|-------------------|------------------------------------------------------|
| <i>base</i>       | The IRTC peripheral base pointer.                    |
| <i>statusFlag</i> | The status flag, defined in type irtc_status_flag_t. |

Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

**34.2.7.25 static void IRTC\_HAL\_SetIntCmd ( RTC\_Type \* *base*, irtc\_int\_t *interrupt*, bool *enable* ) [inline], [static]**

Parameters

|                  |                                                               |
|------------------|---------------------------------------------------------------|
| <i>base</i>      | The IRTC peripheral base pointer.                             |
| <i>interrupt</i> | The interrupt name, defined in type <code>irtc_int_t</code> . |
| <i>enable</i>    | Enable (true) or disable (false) related interrupt.           |

**34.2.7.26** `static bool IRTC_HAL_GetIntCmd ( RTC_Type * base, irtc_int_t interrupt ) [inline], [static]`

Parameters

|                  |                                                               |
|------------------|---------------------------------------------------------------|
| <i>base</i>      | The IRTC peripheral base pointer.                             |
| <i>interrupt</i> | The interrupt name, defined in type <code>irtc_int_t</code> . |

Returns

State of the interrupt: asserted (true) or not-asserted (false).

- true: related interrupt is being enabled.
- false: related interrupt is not enabled.

**34.2.7.27** `static bool IRTC_HAL_GetIntStatusFlag ( RTC_Type * base, irtc_int_status_flag_t statusFlag ) [inline], [static]`

Parameters

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| <i>base</i>       | The IRTC peripheral base pointer.                                      |
| <i>statusFlag</i> | The status flag, defined in type <code>irtc_int_status_flag_t</code> . |

Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

**34.2.7.28** `static void IRTC_HAL_ClearIntStatusFlag ( RTC_Type * base, irtc_int_status_flag_t statusFlag ) [inline], [static]`

Tamper interrupt status flag is cleared when the TAMPER\_SCR[TMPR\_STS] is cleared.

## IRTC HAL driver

### Parameters

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| <i>base</i>       | The IRTC peripheral base pointer.                                      |
| <i>statusFlag</i> | The status flag, defined in type <code>irtc_int_status_flag_t</code> . |

### 34.2.7.29 void IRTC\_HAL\_SetCoarseCompensation ( RTC\_Type \* *base*, uint8\_t *compVal*, uint8\_t *compInterval* )

### Parameters

|                     |                                               |
|---------------------|-----------------------------------------------|
| <i>base</i>         | The IRTC base address pointer                 |
| <i>compVal</i>      | Compensation value is a 2's complement value. |
| <i>compInterval</i> | Compensation interval.                        |

### 34.2.7.30 void IRTC\_HAL\_SetFineCompensation ( RTC\_Type \* *base*, uint8\_t *integralVal*, uint8\_t *fracVal*, bool *accumulateFrac* )

### Parameters

|                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>            | The IRTC base address pointer                                                                                                                    |
| <i>integralVal</i>     | Compensation integral value is a twos complement value of the integer part.                                                                      |
| <i>fracVal</i>         | Compensation fraction value expressed as number of clock cycles of a fixed 4.-194304Mhz clock that have to be added.                             |
| <i>accumulate-Frac</i> | Flag indicating if we want to add to previous fractional part; true: accumulate fractional part, false: start afresh and overwrite current value |

### 34.2.7.31 static void IRTC\_HAL\_SetClockOutMode ( RTC\_Type \* *base*, irtc\_clock\_output\_t *clock* ) [inline], [static]

### Parameters

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| <i>base</i>  | The IRTC base address pointer.                                         |
| <i>clock</i> | OUtput clock selection from list of <code>irtc_clock_output_t</code> . |

**34.2.7.32 static void IRTC\_HAL\_SoftwareReset ( RTC\_Type \* *base* ) [inline],  
[static]**

This clears the contents of alarm, interrupt (status and enable except tamper interrupt enable bit) registers, STATUS[*CMP\_DONE*], and STATUS[*BUS\_ERR*] and has no effect on DST, calendaring, standby time, and tamper detect registers.

Parameters

|             |                               |
|-------------|-------------------------------|
| <i>base</i> | The IRTC base address pointer |
|-------------|-------------------------------|

**34.2.7.33 void IRTC\_HAL\_ConfigTamperParams ( RTC\_Type \* *base*, irtc\_tamper\_pins\_t *tamperNum*, irtc\_tamper\_config\_t \* *tamperConfig* )**

The function configures the filter properties for the three external tampers i.e., 0, 1, and 2. It also sets up active/passive and direction of the tamper bits, which are not available on all platforms. NOTE: This function programs the tamper filter parameters. The user must gate the 32 K clock to the RTC before calling this function. It is assumed that the time and date are set after this and the tamper parameters do not require to be changed again later.

Parameters

|                     |                                    |
|---------------------|------------------------------------|
| <i>base</i>         | The IRTC base address pointer      |
| <i>tamperNum</i>    | The IRTC tamper input to configure |
| <i>tamperConfig</i> | The IRTC tamper properties         |

**34.2.7.34 static void IRTC\_HAL\_EnableTamper ( RTC\_Type \* *base* ) [inline],  
[static]**

The function should be called after all required tamper features have been configured by calling the IRTC\_HAL\_ConfigTamperParams functions.

Parameters

|             |                               |
|-------------|-------------------------------|
| <i>base</i> | The IRTC base address pointer |
|-------------|-------------------------------|

## IRTC HAL driver

**34.2.7.35** `static void IRTC_HAL_DisableTamper ( RTC_Type * base ) [inline], [static]`

Parameters

|             |                               |
|-------------|-------------------------------|
| <i>base</i> | The IRTC base address pointer |
|-------------|-------------------------------|

## 34.3 IRTC Peripheral Driver

### 34.3.1 Overview

This section describes the programming interface of the IRTC Peripheral Driver. The IRTC Peripheral driver sets and gets the IRTC clock, sets and reads the IRTC alarm time.

### 34.3.2 IRTC Peripheral Driver Initialization

To initialize, call the `IRTC_DRV_Init()` function with the IRTC instance number. Most SoCs have only one IRTC instance. Therefore, the instance number is zero. The driver initialization function un-gates the IRTC module clock, initializes the IRTC HAL layer driver, and enables the IRTC interrupts when an alarm is set.

This is an example how to create the `irtc_init()` function:

```
// init the irtc module //
IRTC_DRV_Init(0);
```

### 34.3.3 IRTCS Setting and reading the IRTC time

The IRTC driver uses an instantiation of the `irtc_datetime_t` structure either to configure or read the date and time. Call the `IRTC_DRV_SetDatetime()` function to configure the current date and time and call the `IRTC_DRV_GetDatetime()` function to read the current date and time at a later time. This example shows how to use these functions:

```
irtc_datetime_t datetimeToSet;

IRTC_DRV_Init(0);

datetimeToSet.year = 2013;
datetimeToSet.month = 10;
datetimeToSet.day = 13;
datetimeToSet.hour = 18;
datetimeToSet.minute = 55;
datetimeToSet.second = 30;

// set the datetime //
result = IRTC_DRV_SetDatetime(0, &datetime);

// get datetime //
IRTC_DRV_GetDatetime(0, &datetime);
printf("Current datetime: %04hd-%02hd-%02hd %02hd:%02hd:%02hd\r\n",
 datetime.year, datetime.month, datetime.day,
 datetime.hour, datetime.minute, datetime.second);
```

### 34.3.4 IRTC Triggering an Alarm

Call the `IRTC_DRV_SetAlarm()` function to set the alarm time and call the `IRTC_DRV_GetAlarm()` function to read the configured alarm time. Set the current time using the steps mentioned earlier prior

## IRTC Peripheral Driver

to using the call to set the alarm time. The user can enable the option to trigger an interrupt when an alarm occurs. This is done by calling the `IRTC_DRV_SetIntCmd()` and `IRTC_DRV_SetAlarmMatchMode()` functions. This is an example to set an IRTC alarm. This example causes an alarm interrupt to be triggered after 5 minutes.

```

irtc_datetime_t datetimeToSet;
irtc_datetime_t alrmTimeToSet;

IRTC_DRV_Init(0);

datetimeToSet.year = 2013;
datetimeToSet.month = 10;
datetimeToSet.day = 13;
datetimeToSet.hour = 18;
datetimeToSet.minute = 55;
datetimeToSet.second = 30;

IRTC_DRV_SetDatetime(0, &datetimeToSet);

alrmTimeToSet.year = datetimeToSet.year;
alrmTimeToSet.month = datetimeToSet.month;
alrmTimeToSet.day = datetimeToSet.day;
alrmTimeToSet.minute = datetimeToSet.minute + 5;
alrmTimeToSet.second = datetimeToSet.second;
IRTC_DRV_SetAlarm(0, &alrmTimeToSet);
IRTC_DRV_SetAlarmMatchMode(0,
 kIRTCSecMinHourDayMonYear);
IRTC_HAL_SetIntCmd(0, kIRTCAlarmIntFlag);

```

## Variables

- `RTC_Type *const g_irtcBase` [RTC\_INSTANCE\_COUNT]  
*Table of base addresses for IRTC instances.*
- `const IRQn_Type g_irtcIrqId` [RTC\_INSTANCE\_COUNT]  
*Table to save IRTC Alarm IRQ numbers for IRTC instances.*

## Initialization and De-initialization

- `irtc_status_t IRTC_DRV_Init` (uint32\_t instance, const `irtc_datetime_t *datetime`, const `irtc_datetime_t *alarmDatetime`, `irtc_alarm_match_t alarmMode`, const `irtc_daylight_time_t *daylightTime`)  
*Initializes the IRTC module.*
- `irtc_status_t IRTC_DRV_Deinit` (uint32\_t instance)  
*Disables the IRTC module clock gate control.*

## IRTC Datetime Set and Get

- static void `IRTC_DRV_SetDatetime` (uint32\_t instance, `irtc_datetime_t *datetime`)  
*Sets the IRTC date and time according to the given time structure.*
- static void `IRTC_DRV_GetDatetime` (uint32\_t instance, `irtc_datetime_t *datetime`)  
*Gets the IRTC time and stores it in the given time structure.*

### IRTC Alarm

- static void [IRTC\\_DRV\\_SetAlarmMatchMode](#) (uint32\_t instance, [irtc\\_alarm\\_match\\_t](#) alarmType)  
*Sets the alarm match type.*
- static void [IRTC\\_DRV\\_SetAlarm](#) (uint32\_t instance, [irtc\\_datetime\\_t](#) \*alarmTime)  
*Sets the IRTC alarm time.*
- static void [IRTC\\_DRV\\_GetAlarm](#) (uint32\_t instance, [irtc\\_datetime\\_t](#) \*date)  
*Returns the IRTC alarm time.*

### Interrupts

- static void [IRTC\\_DRV\\_SetIntCmd](#) (uint32\_t instance, [irtc\\_int\\_t](#) interrupt, bool enable)  
*Enables or disables the related IRTC interrupt.*
- static bool [IRTC\\_DRV\\_GetIntCmd](#) (uint32\_t instance, [irtc\\_int\\_t](#) interrupt)  
*Gets whether the IRTC interrupt is enabled or not.*
- static bool [IRTC\\_DRV\\_GetIntStatusFlag](#) (uint32\_t instance, [irtc\\_int\\_status\\_flag\\_t](#) statusFlag)  
*Gets the IRTC interrupt status flag state.*
- static void [IRTC\\_DRV\\_ClearIntStatusFlag](#) (uint32\_t instance, [irtc\\_int\\_status\\_flag\\_t](#) statusFlag)  
*Clears the IRTC interrupt status flag.*

### 34.3.5 Function Documentation

#### 34.3.5.1 [irtc\\_status\\_t](#) IRTC\_DRV\_Init ( uint32\_t instance, const [irtc\\_datetime\\_t](#) \* datetime, const [irtc\\_datetime\\_t](#) \* alarmDatetime, [irtc\\_alarm\\_match\\_t](#) alarmMode, const [irtc\\_daylight\\_time\\_t](#) \* daylightTime )

Enables the IRTC clock and interrupts if requested by the user.

Parameters

|                      |                                                          |
|----------------------|----------------------------------------------------------|
| <i>instance</i>      | The IRTC peripheral instance number.                     |
| <i>datetime</i>      | Date and time need to set, pass NULL to ignore.          |
| <i>alarmDatetime</i> | Alarm of date and time need to set, pass NULL to ignore. |
| <i>alarmMode</i>     | Alarm mode to set when will generate alarm.              |
| <i>daylightTime</i>  | Daylight saving time need to set, pass NULL to ignore.   |

Returns

Error or success returned by API.

#### 34.3.5.2 [irtc\\_status\\_t](#) IRTC\_DRV\_Deinit ( uint32\_t instance )

## IRTC Peripheral Driver

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | The IRTC peripheral instance number. |
|-----------------|--------------------------------------|

### Returns

Error or success returned by API.

**34.3.5.3 static void IRTC\_DRV\_SetDatetime ( uint32\_t *instance*, irtc\_datetime\_t \* *datetime* ) [inline], [static]**

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The IRTC peripheral instance number.                                    |
| <i>datetime</i> | Pointer to structure where the date and time details to set are stored. |

**34.3.5.4 static void IRTC\_DRV\_GetDatetime ( uint32\_t *instance*, irtc\_datetime\_t \* *datetime* ) [inline], [static]**

### Parameters

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <i>instance</i> | The IRTC peripheral instance number.                             |
| <i>datetime</i> | Pointer to structure where the date and time details are stored. |

**34.3.5.5 static void IRTC\_DRV\_SetAlarmMatchMode ( uint32\_t *instance*, irtc\_alarm\_match\_t *alarmType* ) [inline], [static]**

### Parameters

|                  |                                                        |
|------------------|--------------------------------------------------------|
| <i>instance</i>  | The IRTC peripheral instance number.                   |
| <i>alarmType</i> | Alarm match selections that when an alarm will happen. |

**34.3.5.6 static void IRTC\_DRV\_SetAlarm ( uint32\_t *instance*, irtc\_datetime\_t \* *alarmTime* ) [inline], [static]**

### Parameters

|                  |                                                     |
|------------------|-----------------------------------------------------|
| <i>instance</i>  | The IRTC peripheral instance number.                |
| <i>alarmTime</i> | Pointer to structure where the alarm time is store. |

**34.3.5.7** `static void IRTC_DRV_GetAlarm ( uint32_t instance, irtc_datetime_t * date ) [inline], [static]`

### Parameters

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <i>instance</i> | The IRTC peripheral instance number.                                   |
| <i>date</i>     | Pointer to structure where the alarm date and time details are stored. |

**34.3.5.8** `static void IRTC_DRV_SetIntCmd ( uint32_t instance, irtc_int_t interrupt, bool enable ) [inline], [static]`

### Parameters

|                  |                                                   |
|------------------|---------------------------------------------------|
| <i>instance</i>  | The IRTC peripheral instance number.              |
| <i>interrupt</i> | The interrupt name, defined in type irtc_int_t.   |
| <i>enable</i>    | Enable(true) or disable(false) related interrupt. |

**34.3.5.9** `static bool IRTC_DRV_GetIntCmd ( uint32_t instance, irtc_int_t interrupt ) [inline], [static]`

### Parameters

|                  |                                                 |
|------------------|-------------------------------------------------|
| <i>instance</i>  | The IRTC peripheral instance number.            |
| <i>interrupt</i> | The interrupt name, defined in type irtc_int_t. |

### Returns

State of the interrupt: asserted (true) or not-asserted (false).

- true: related interrupt is being enabled.
- false: related interrupt is not enabled.

**34.3.5.10** `static bool IRTC_DRV_GetIntStatusFlag ( uint32_t instance, irtc_int_status_flag_t statusFlag ) [inline], [static]`

## IRTC Peripheral Driver

### Parameters

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| <i>instance</i>   | The IRTC peripheral instance number.                                   |
| <i>statusFlag</i> | The status flag, defined in type <code>irtc_int_status_flag_t</code> . |

### Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

**34.3.5.11** `static void IRTC_DRV_ClearIntStatusFlag ( uint32_t instance, irtc_int_status_flag_t statusFlag ) [inline], [static]`

Tamper interrupt status flag is cleared when the TAMPER\_SCR[TMPR\_STS] is cleared.

### Parameters

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| <i>instance</i>   | The IRTC peripheral instance number.                                   |
| <i>statusFlag</i> | The status flag, defined in type <code>irtc_int_status_flag_t</code> . |

## 34.3.6 Variable Documentation

**34.3.6.2** `const IRQn_Type g_irtclrqld[RTC_INSTANCE_COUNT]`

## Chapter 35

# Low-Leakage Wakeup Unit (LLWU)

### 35.1 Overview

The Kinetis SDK provides a HAL driver for the Low-Leakage Wakeup Unit (LLWU) block of Kinetis devices. The LLWU module allows the user to configure external wakeup pin and internal wakeup modules as a wakeup source from low-leakage power modes.

### 35.2 External Wakeup Pin APIs

Different platforms may have different wakeup pin assignments. Check the reference manual for details. The external wakeup pin can be configured with the function `LLWU_HAL_SetExternalInputPinMode()`.

After wakeup, flags indicate which external pin is the wakeup source. Use the function `LLWU_HAL_GetExternalPinWakeupFlag()` to check the external pin wakeup flags. The function `LLWU_HAL_ClearExternalPinWakeupFlag()` clears the wakeup flags.

For external pins, there is the pin filter. The function `LLWU_HAL_SetPinFilterMode()` configures the pin filter for a specific pin and configures the filter mode.

### 35.3 Internal Wakeup Module APIs

Different platforms may have different wakeup module assignments. Check the reference manual for details. The internal wakeup module can be enabled/disabled with the function `LLWU_HAL_SetInternalModuleCmd()`.

After wakeup, flags indicate which module is the wakeup source. Use the function `LLWU_HAL_GetInternalModuleWakeupFlag()` to check the internal module wakeup flags. There is no API to clear internal wakeup module flags. Clear the wakeup source status directly.

### 35.4 Reset Pin Configure APIs

The RESET pin can be configured as a low-leakage mode exit source. The function `LLWU_HAL_SetResetPinMode()` sets this feature and configures the RESET pin filter.

## 35.6 Enumeration Type Documentation

### 35.6.1 enum `llwu_external_pin_modes_t`

Enumerator

***kLlwuExternalPinDisabled*** Pin disabled as wakeup input.

*kLlwuExternalPinRisingEdge* Pin enabled with rising edge detection.  
*kLlwuExternalPinFallingEdge* Pin enabled with falling edge detection.  
*kLlwuExternalPinChangeDetect* Pin enabled with any change detection.

### 35.6.2 enum llwu\_filter\_modes\_t

Enumerator

*kLlwuFilterDisabled* Filter disabled.  
*kLlwuFilterPosEdgeDetect* Filter positive edge detection.  
*kLlwuFilterNegEdgeDetect* Filter negative edge detection.  
*kLlwuFilterAnyEdgeDetect* Filter any edge detection.

## Chapter 36

# Local Memory Controller (LMEM) Cache Control Driver

### 36.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Local Memory Controller Cache Controller. The Kinetis devices contain a Processor Code (PC) bus and a Processor System (PS) bus. Depending on the specific Kinetis MCU device, there may be a cache controller for both the PC bus and PS bus or there may only be one cache controller for the PC bus. Refer to the Kinetis reference manual to ascertain the availability of the cache. The LMEM Cache driver allows the user to enable/disable the cache and to perform cache maintenance operations such as invalidate, push, and clear. These maintenance operations may be performed on the entire cache or on a line-basis.

### Modules

- [LMEM Cache Driver](#)
- [LMEM Cache HAL driver](#)

## LMEM Cache Driver

### 36.2 LMEM Cache Driver

#### 36.2.1 Overview

This section describes the programming interface of the LMEM Cache peripheral driver. The LMEM Cache peripheral driver allows the user to enable/disable the cache and to perform cache maintenance operations such as invalidate, push, and clear. These maintenance operations may be performed on the entire cache or on a line-basis. In addition, the the driver also allows the user to "demote" the cache mode of a region within the device's memory map.

#### 36.2.2 LMEM Cache Driver Definitions and Usage

The following provides definitions to the terms commonly used in the LMEM Cache peripheral driver and how to use the various functions.

The Cortex-M4 processor has a modified 32-bit Harvard bus architecture. Processor Code (PC) bus - a 32-bit address space bus with low-order addresses (0x0000\_0000 through 0x1FFF\_FFFF) used normally for code access.

Processor System (PS) bus - a 32-bit address space bus with high-order addresses (0x2000\_0000 through 0xFFFF\_FFFF) used normally for data accesses.

Some Kinetis MCU devices have caches available for the PC bus and PS bus, some may only have a PC bus cache, while some do not have PC or PS caches at all. Refer to the desired Kinetis reference manual for cache availability.

Cache maintenance operations: Invalidate - Unconditionally clear valid and modify bits of a cache entry.

Push - Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is. This action does not clear the valid bit. A cache push is synonymous with a cache flush.

Clear - Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

The above cache maintenance operations may be performed on the entire cache or on a line-basis. The peripheral driver API names distinguish between the two using the terms "All" or "Line". For example, to perform an invalidate all on the PC bus, the API is called:

```
LMEM_DRV_CodeCacheInvalidateAll(uint32_t instance);
```

To invalidate a particular line, simple call:

```
LMEM_DRV_CodeCacheInvalidateLine(uint32_t instance, uint32_t addr);
```

Note that the parameter "addr" must be supplied which indicates the physical address of the line you wish to perform the cache maintenance operation.

In addition, if the user wishes to perform cache maintenance operations on multiple lines, there are APIs available which use the naming convention "MultiLines". For example, to perform a multi-line push on the PC bus, the API is called:

```
LMEM_DRV_CodeCachePushMultiLines(uint32_t instance, uint32_t addr, uint32_t
 length);
```

Note that the parameter "addr" must be supplied which indicates the starting physical address of the lines you wish to perform the cache maintenance operation. In addition, the length is the number of bytes you wish to perform the cache maintenance operation. The function will determine if the length meets or exceeds 1/2 the cache size (as the cache contains 2 WAYs, half of the cache is in WAY0 and the other half in WAY1) and if so, will perform a cache maintenance "all" operation which is faster than performing the cache maintenance on a line-basis.

Cache Demotion: Cache region demotion - Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. The cache region demote function checks to see if the requested cache mode is higher than or equal to the current cache mode, and if so, will return an error. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state. NOTE: The address/module assignment of the 16 subregions is device-specific and are detailed in the Chip Configuration chapter of the Kinetis reference manual. Some of the regions may not be used (non-cacheable), and some regions may not be capable of write-back.

To demote a cache region, simple call this function:

```
LMEM_DRV_CodeCacheDemoteRegion(uint32_t instance,
 lmem_cache_region_t region,
 lmem_cache_mode_t cacheMode);
```

The parameter region is of type lmem\_cache\_region\_t. This provides typedef enums for each of the 16 regions, starting with "kCacheRegion0" and ending with "kCacheRegion15". The parameter cacheMode is of type lmem\_cache\_mode\_t. This provides typedef enums for each of the cache modes: "kCacheNon-Cacheable", "kCacheWriteThrough", and "kCacheWriteBack".

Cache Enable/Disable: The cache enable function enables the PC or PS bus cache as well as the write buffer. However, before enabling these, the function first performs an invalidate all. The user should call this function if they wish to enable a particular bus cache. For example, to enable the Processor Code bus cache, call the function:

```
LMEM_DRV_CodeCacheEnable(uint32_t instance);
```

To enable the Processor System bus cache, call the function:

```
LMEM_DRV_SystemCacheEnable(uint32_t instance);
```

The cache disable function disables the PC or PS bus cache as well as the write buffer. Before disabling these, the function first performs a push all. The user should call this function if they wish to disable a particular bus cache. For example, to disable the Processor Code bus cache, call the function:

## LMEM Cache Driver

```
LMEM_DRV_CodeCacheDisable(uint32_t instance);
```

To Disable the Processor System bus cache, call the function:

```
LMEM_DRV_SystemCacheDisable(uint32_t instance);
```

## 36.2.3 Function Documentation

### 36.2.3.1 void LMEM\_DRV\_CodeCacheInvalidateAll ( uint32\_t instance )

This function invalidates the cache both ways, which means that it unconditionally clears valid bits and modifies bits of a cache entry.

Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
|-----------------|--------------------------------------------|

**36.2.3.2 void LMEM\_DRV\_CodeCachePushAll ( uint32\_t *instance* )**

This function pushes all modified lines in both ways (the entire cache). Pushes a cache entry if it is valid and modified, then clears the modify bit. If entry is not valid or not modified, leave as is. This action does not clear the valid bit. A cache push is synonymous with a cache flush.

Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
|-----------------|--------------------------------------------|

**36.2.3.3 void LMEM\_DRV\_CodeCacheClearAll ( uint32\_t *instance* )**

This function clears the entire cache and pushes (flushes) and invalidates the operation. Clear - Push a cache entry if it is valid and modified, then clear the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
|-----------------|--------------------------------------------|

**36.2.3.4 void LMEM\_DRV\_CodeCacheEnable ( uint32\_t *instance* )**

This function enables the cache. The function first invalidates the entire cache, then enables both the cache and write buffer.

Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
|-----------------|--------------------------------------------|

**36.2.3.5 void LMEM\_DRV\_CodeCacheDisable ( uint32\_t *instance* )**

This function disables the cache and write buffer.

## LMEM Cache Driver

### Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
|-----------------|--------------------------------------------|

### 36.2.3.6 void LMEM\_DRV\_CodeCacheInvalidateLine ( uint32\_t *instance*, uint32\_t *addr* )

This function invalidates a specific line in the cache based on the physical address passed in by the user. Invalidate - Unconditionally clear valid and modify bits of a cache entry

### Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
| <i>addr</i>     | The physical address of the cache line     |

### 36.2.3.7 void LMEM\_DRV\_CodeCacheInvalidateMultiLines ( uint32\_t *instance*, uint32\_t *addr*, uint32\_t *length* )

This function invalidates multiple lines in the cache based on the physical address and length in bytes passed in by the user. If the function detects that the length meets or exceeds half the cache, then the function performs an entire cache invalidate function which is more efficient than invalidating the cache line-by-line. The need to check half the total amount of cache is due to the fact that the cache consists of two ways and that line commands based on the physical address searches both ways. Invalidate - Unconditionally clear valid and modify bits of a cache entry

### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral             |
| <i>addr</i>     | The physical address of the cache line                 |
| <i>length</i>   | The length in bytes of the total amount of cache lines |

### 36.2.3.8 void LMEM\_DRV\_CodeCachePushLine ( uint32\_t *instance*, uint32\_t *addr* )

This function pushes a specific modified line based on the physical address passed in by the user. Push - Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is. This action does not clear the valid bit. A cache push is synonymous with a cache flush.

## Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
| <i>addr</i>     | The physical address of the cache line     |

**36.2.3.9 void LMEM\_DRV\_CodeCachePushMultiLines ( uint32\_t *instance*, uint32\_t *addr*, uint32\_t *length* )**

This function pushes multiple modified lines in the cache based on the physical address and length in bytes passed in by the user. If the function detects that the length meets or exceeds half of the cache, the function performs an cache push function (which is more efficient than pushing the modified lines in the cache line-by-line). The need to check half the total amount of cache is due to the fact that the cache consists of two ways and that line commands based on the physical address searches both ways. Push - Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is. This action does not clear the valid bit. A cache push is synonymous with a cache flush.

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral             |
| <i>addr</i>     | The physical address of the cache line                 |
| <i>length</i>   | The length in bytes of the total amount of cache lines |

**36.2.3.10 void LMEM\_DRV\_CodeCacheClearLine ( uint32\_t *instance*, uint32\_t *addr* )**

This function clears a specific line based on the physical address passed in by the user. Clear - Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

## Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral |
| <i>addr</i>     | The physical address of the cache line     |

**36.2.3.11 void LMEM\_DRV\_CodeCacheClearMultiLines ( uint32\_t *instance*, uint32\_t *addr*, uint32\_t *length* )**

This function clears multiple lines in the cache based on the physical address and length in bytes passed in by the user. If the function detects that the length meets or exceeds half the total amount of cache, the function performs a cache clear function which is more efficient than clearing the lines in the cache line-by-line. The need to check half the total amount of cache is due to the fact that the cache consists of two ways and that line commands based on the physical address searches both ways. Clear - Push a cache

## LMEM Cache Driver

entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | The instance number of the LMEM peripheral             |
| <i>addr</i>     | The physical address of the cache line                 |
| <i>length</i>   | The length in bytes of the total amount of cache lines |

### 36.2.3.12 `lmem_cache_status_t` LMEM\_DRV\_CodeCacheDemoteRegion ( `uint32_t instance`, `lmem_cache_region_t region`, `lmem_cache_mode_t cacheMode` )

This function allows the user to demote the cache mode of a region within the device's memory map. Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. The function checks to see if the requested cache mode is higher than or equal to the current cache mode, and if so, returns an error. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state. To maintain cache coherency, changes to the cache mode should be completed while the address space being changed is not being accessed or the cache is disabled. Before a cache mode change, this function completes a cache clear all command to push and invalidate any cache entries that may have changed.

Parameters

|                  |                                                                       |
|------------------|-----------------------------------------------------------------------|
| <i>instance</i>  | The instance number of the LMEM peripheral                            |
| <i>region</i>    | The desired region to demote of type <code>lmem_cache_region_t</code> |
| <i>cacheMode</i> | The new, demoted cache mode of type <code>lmem_cache_mode_t</code>    |

Returns

`kStatus_LMEM_CACHE_Success` The cache clear operation was successful, or `kStatus_LMEM_CACHE_Busy` The cache is busy performing another operation `kStatus_LMEM_CACHE_Error` The requested cache mode is higher than or equal to the current cache mode

*Sets the cache mode for a specific region for the Processor Code bus.*
- uint32\_t `LMEM_HAL_GetCodeCacheRegionMode` (LMEM\_Type \*base, `lmem_cache_region_t` region)  
*Gets the current cache mode for a specific region for the Processor Code bus.*

### 36.3.2 Macro Definition Documentation

#### 36.3.2.1 #define LMEM\_CACHE\_LINE\_SIZE 0x10

Cache line is 32 bytes (or 4-words)

### 36.3.3 Enumeration Type Documentation

#### 36.3.3.1 enum lmem\_cache\_status\_t

Enumerator

- kStatus\_LMEM\_CACHE\_Busy* CACHE busy performing an operation.
- kStatus\_LMEM\_CACHE\_DemoteError* CACHE region demotion error.
- kStatus\_LMEM\_CACHE\_Error* CACHE driver error.

#### 36.3.3.2 enum lmem\_cache\_mode\_t

Enumerator

- kCacheNonCacheable* CACHE mode: non-cacheable.
- kCacheWriteThrough* CACHE mode: write-through.
- kCacheWriteBack* CACHE mode: write-back.

#### 36.3.3.3 enum lmem\_cache\_region\_t

Enumerator

- kCacheRegion0* Cache Region 0.
- kCacheRegion1* Cache Region 1.
- kCacheRegion2* Cache Region 2.
- kCacheRegion3* Cache Region 3.
- kCacheRegion4* Cache Region 4.
- kCacheRegion5* Cache Region 5.
- kCacheRegion6* Cache Region 6.
- kCacheRegion7* Cache Region 7.
- kCacheRegion8* Cache Region 8.
- kCacheRegion9* Cache Region 9.
- kCacheRegion10* Cache Region 10.
- kCacheRegion11* Cache Region 11.
- kCacheRegion12* Cache Region 12.
- kCacheRegion13* Cache Region 13.
- kCacheRegion14* Cache Region 14.
- kCacheRegion15* Cache Region 15.

#### 36.3.3.4 enum lmem\_cache\_line\_command\_t

Enumerator

- kCacheLineSearchReadOrWrite* Cache line search and read or write.

## LMEM Cache HAL driver

*kCacheLineInvalidate* Cache line invalidate.

*kCacheLinePush* Cache line push.

*kCacheLineClear* Cache line clear.

### 36.3.4 Function Documentation

#### 36.3.4.1 `static void LMEM_HAL_SetCodeCacheEnableCmd ( LMEM_Type * base, bool enable ) [inline], [static]`

This function enables or disables the Processor Code bus cache and write buffer.

Parameters

|               |                                                                                |
|---------------|--------------------------------------------------------------------------------|
| <i>base</i>   | Module base pointer of type LMEM_Type.                                         |
| <i>enable</i> | Enable (true) or disable (false) the Processor Code bus cache and write buffer |

#### 36.3.4.2 `void LMEM_HAL_SetCodeCacheInvalidateAllCmd ( LMEM_Type * base, bool enable )`

This function enables or disables the Processor Code bus option to invalidate all lines in both WAYs.

Parameters

|               |                                                                                        |
|---------------|----------------------------------------------------------------------------------------|
| <i>base</i>   | Module base pointer of type LMEM_Type.                                                 |
| <i>enable</i> | Enable (true) or disable (false) the Processor Code bus option to invalidate all lines |

#### 36.3.4.3 `void LMEM_HAL_SetCodeCachePushAllCmd ( LMEM_Type * base, bool enable )`

This function enables or disables the Processor Code bus option to push all modified lines to both WAYs.

Parameters

|               |                                                                                           |
|---------------|-------------------------------------------------------------------------------------------|
| <i>base</i>   | Module base pointer of type LMEM_Type.                                                    |
| <i>enable</i> | Enable (true) or disable (false) the Processor Code bus option to push all modified lines |

**36.3.4.4 void LMEM\_HAL\_SetCodeCacheClearAllCmd ( LMEM\_Type \* *base*, bool *enable* )**

This function enables or disables the Processor Code bus option to push and invalidate all modified lines.

Parameters

|               |                                                                                           |
|---------------|-------------------------------------------------------------------------------------------|
| <i>base</i>   | Module base pointer of type LMEM_Type.                                                    |
| <i>enable</i> | Enable (true) or disable (false) the Processor Code bus option to push all modified lines |

**36.3.4.5 static void LMEM\_HAL\_InitiateCodeCacheCommand ( LMEM\_Type \* *base* )  
[inline], [static]**

This function initiates the Processor Code bus cache command to execute an invalidate command and/or push command.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | Module base pointer of type LMEM_Type. |
|-------------|----------------------------------------|

**36.3.4.6 static bool LMEM\_HAL\_IsCodeCacheCommandActive ( LMEM\_Type \* *base* )  
[inline], [static]**

This function returns the state of the Processor Code bus cache command. The command is either active (in progress) or idle.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | Module base pointer of type LMEM_Type. |
|-------------|----------------------------------------|

Returns

True if the cache command is in progress or false if the command is idle

**36.3.4.7 static void LMEM\_HAL\_InitiateCodeCacheLineCommand ( LMEM\_Type \* *base* )  
[inline], [static]**

This function initiates the Processor Code bus cache line command to execute a search and read or write command, an invalidate command, a push command, or a clear command.

## LMEM Cache HAL driver

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | Module base pointer of type LMEM_Type. |
|-------------|----------------------------------------|

**36.3.4.8 static bool LMEM\_HAL\_IsCodeCacheLineCommandActive ( LMEM\_Type \* *base* ) [inline], [static]**

This function returns the state of the Processor Code bus cache line command. The command is either active (in progress) or idle.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>base</i> | Module base pointer of type LMEM_Type. |
|-------------|----------------------------------------|

Returns

True if the cache line command is in progress or false if the command is idle

**36.3.4.9 static void LMEM\_HAL\_SetCodeCacheLineCommand ( LMEM\_Type \* *base*, lmem\_cache\_line\_command\_t *command* ) [inline], [static]**

This function sets the cache line command for the Processor Code bus. The command can be search and read or write, invalidate, push, or clear.

Parameters

|                |                                                          |
|----------------|----------------------------------------------------------|
| <i>base</i>    | Module base pointer of type LMEM_Type.                   |
| <i>command</i> | The cache line command of type lmem_cache_line_command_t |

**36.3.4.10 static void LMEM\_HAL\_SetCodeCachePhysicalAddr ( LMEM\_Type \* *base*, uint32\_t *addr* ) [inline], [static]**

This function sets the physical address for cache line commands for the Processor Code bus. The commands are specified in the CLCR[LADSEL] bits.

Parameters

---

|             |                                              |
|-------------|----------------------------------------------|
| <i>base</i> | Module base pointer of type LMEM_Type.       |
| <i>addr</i> | The physical address for cache line commands |

**36.3.4.11 void LMEM\_HAL\_SetCodeCacheRegionMode ( LMEM\_Type \* *base*,  
lmem\_cache\_region\_t *region*, lmem\_cache\_mode\_t *cacheMode* )**

This function sets the cache mode for a specific region for the Processor Code bus. Note that you can only demote the cache mode.

Parameters

|                  |                                                                 |
|------------------|-----------------------------------------------------------------|
| <i>base</i>      | Module base pointer of type LMEM_Type.                          |
| <i>region</i>    | The region to demote the cache mode of type lmem_cache_region_t |
| <i>cacheMode</i> | The specified demoted cache mode of type lmem_cache_mode_t      |

**36.3.4.12 uint32\_t LMEM\_HAL\_GetCodeCacheRegionMode ( LMEM\_Type \* *base*,  
lmem\_cache\_region\_t *region* )**

This function gets the current cache mode for a specific region for the Processor Code bus.

Parameters

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <i>base</i>   | Module base pointer of type LMEM_Type.                          |
| <i>region</i> | The region to obtain the cache mode of type lmem_cache_region_t |

Returns

The current cache mode for the specified region

---

## Chapter 37

### LP Inter-Integrated Circuit (LPI2C)

#### 37.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the LP Inter-Integrated Circuit (LPI2C) block of Kinetis devices.

#### Modules

- [LPI2C HAL driver](#)
- [LPI2C Master peripheral](#)
- [LPI2C Slave peripheral driver](#)

## LPI2C HAL driver

### 37.2 LPI2C HAL driver

#### 37.2.1 Overview

This section describes the programming interface of the LPI2C HAL driver.

#### 37.2.2 LPI2C ICR Table

| ICR (hex) | SCL divider | SDA hold value | SCL start hold value | SCL stop hold value |
|-----------|-------------|----------------|----------------------|---------------------|
| 00        | 20          | 7              | 6                    | 11                  |
| 01        | 22          | 7              | 7                    | 12                  |
| 02        | 24          | 8              | 8                    | 13                  |
| 03        | 26          | 8              | 9                    | 14                  |
| 04        | 28          | 9              | 10                   | 15                  |
| 05        | 30          | 9              | 11                   | 16                  |
| 06        | 34          | 10             | 13                   | 18                  |
| 07        | 40          | 10             | 16                   | 21                  |

#### 37.2.3 I2C Clock rate formulas

I2C baud rate =  $\text{bus\_clock\_Hz} / (\text{mult} * \text{SCL\_divider})$

SDA hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SDA\_hold\_value}$

SCL start hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SCL\_start\_hold\_value}$

SCL stop hold time =  $\text{bus\_clock\_period\_s} * \text{mult} * \text{SCL\_stop\_hold\_value}$

## Enumerations

- enum `lpi2c_status_t` {
  - `kStatus_LPI2C_Success` = 0x0U,
  - `kStatus_LPI2C_Initialized` = 0x1U,
  - `kStatus_LPI2C_Fail` = 0x2U,
  - `kStatus_LPI2C_Busy` = 0x3U,
  - `kStatus_LPI2C_Timeout` = 0x4U,
  - `kStatus_LPI2C_ReceivedNak` = 0x5U,
  - `kStatus_LPI2C_SlaveTxUnderrun` = 0x6U,
  - `kStatus_LPI2C_SlaveRxOverrun` = 0x7U,
  - `kStatus_LPI2C_ArbitrationLost` = 0x8U,
  - `kStatus_LPI2C_StopSignalFail` = 0x9U,
  - `kStatus_LPI2C_Idle` = 0xAU,
  - `kStatus_LPI2C_NoReceiveInProgress` = 0xBU,
  - `kStatus_LPI2C_NoSendInProgress` = 0xCU }

*LPI2C status return codes.*
- enum `lpi2c_master_status_t`

*LPI2C master status.*
- enum `lpi2c_master_interrupt_t`

*LPI2C interrupts.*
- enum `lpi2c_slave_status_t`

*LPI2C slave status.*
- enum `lpi2c_slave_interrupt_t`

*LPI2C interrupts.*
- enum `lpi2c_direction_t` { `kLPI2CWrite` }

*Direction of master and slave transfers.*

## Module controls

- void `LPI2C_HAL_Init` (`LPI2C_Type *base`)
 

*Restores the LPI2C peripheral to reset state.*
- static void `LPI2C_HAL_SetMasterCmd` (`LPI2C_Type *base`, bool enable)
 

*Enables/disables the LPI2C module as a master.*
- static void `LPI2C_HAL_SetSlaveCmd` (`LPI2C_Type *base`, bool enable)
 

*Enables/disables the LPI2C module as a slave.*

## Status

- static bool `LPI2C_HAL_MasterGetStatus` (`LPI2C_Type *base`, `lpi2c_master_status_t` statusFlag)
 

*Gets the LPI2C status flag state.*
- static void `LPI2C_HAL_MasterClearStatus` (`LPI2C_Type *base`, `lpi2c_master_status_t` statusFlag)
 

*Clears the LPI2C status flag state.*
- static bool `LPI2C_HAL_SlaveGetStatus` (`LPI2C_Type *base`, `lpi2c_slave_status_t` statusFlag)
 

*Gets the LPI2C status flag state.*
- static void `LPI2C_HAL_SlaveClearStatus` (`LPI2C_Type *base`, `lpi2c_slave_status_t` statusFlag)

## LPI2C HAL driver

*Clears the LPI2C status flag state.*

### Interrupt

- void [LPI2C\\_HAL\\_MasterSetIntCmd](#) (LPI2C\_Type \*base, [lpi2c\\_master\\_interrupt\\_t](#) interrupt, bool enable)  
*Enables or disables specific LPI2C master interrupt.*
- static bool [LPI2C\\_HAL\\_MasterGetIntCmd](#) (LPI2C\_Type \*base, [lpi2c\\_master\\_interrupt\\_t](#) interrupt)  
*Returns whether the LPI2C master interrupt is enabled.*
- void [LPI2C\\_HAL\\_SlaveSetIntCmd](#) (LPI2C\_Type \*base, [lpi2c\\_slave\\_interrupt\\_t](#) interrupt, bool enable)  
*Enables or disables a specific LPI2C slave interrupt.*
- static bool [LPI2C\\_HAL\\_SlaveGetIntCmd](#) (LPI2C\_Type \*base, [lpi2c\\_slave\\_interrupt\\_t](#) interrupt)  
*Returns whether the LPI2C slave interrupt is enabled.*

### Baud rate

- void [LPI2C\\_HAL\\_SetBaudRate](#) (LPI2C\_Type \*base, uint32\_t sourceClockInHz, uint32\_t kbps)  
*Sets the LPI2C bus frequency for master transactions.*

### Bus operations

- void [LPI2C\\_HAL\\_SendStart](#) (LPI2C\_Type \*base, uint8\_t address, [lpi2c\\_direction\\_t](#) dir)  
*Sends a start or a repeated start signal on the LPI2C bus.*
- [lpi2c\\_status\\_t](#) [LPI2C\\_HAL\\_SendStop](#) (LPI2C\_Type \*base)  
*Sends a stop signal on the LPI2C bus.*
- static void [LPI2C\\_HAL\\_SlaveSendAck](#) (LPI2C\_Type \*base)  
*Causes an ACK to be sent on the bus.*
- static void [LPI2C\\_HAL\\_SlaveSendNak](#) (LPI2C\_Type \*base)  
*Causes a NAK to be sent on the bus.*
- static void [LPI2C\\_HAL\\_MasterSetRxMode](#) (LPI2C\_Type \*base, uint8\_t rxSize)  
*Selects either transmit or receive mode.*

### Slave address

- void [LPI2C\\_HAL\\_SetAddress7bit](#) (LPI2C\_Type \*base, uint8\_t address)  
*Sets the primary 7-bit slave address.*
- void [LPI2C\\_HAL\\_SetAddress10bit](#) (LPI2C\_Type \*base, uint16\_t address)  
*Sets the primary slave address and enables 10-bit address mode.*

### Data transfer

- static uint8\_t [LPI2C\\_HAL\\_MasterReadByte](#) (LPI2C\_Type \*base)  
*Returns the last byte of data read from the bus and initiate another read.*

- static void [LPI2C\\_HAL\\_MasterWriteByte](#) (LPI2C\_Type \*base, uint8\_t byte)  
*Writes one byte of data to the LPI2C bus.*
- static uint8\_t [LPI2C\\_HAL\\_SlaveReadByte](#) (LPI2C\_Type \*base)  
*Returns the last byte of data read from the slave.*
- static void [LPI2C\\_HAL\\_SlaveWriteByte](#) (LPI2C\_Type \*base, uint8\_t byte)  
*Writes one byte of data to the LPI2C slave transmit FIFO.*
- bool [LPI2C\\_HAL\\_SlaveWriteByteBlocking](#) (LPI2C\_Type \*base, uint8\_t byte)  
*Writes one byte of data to the LPI2C bus and waits till that byte is transferred successfully.*
- uint8\_t [LPI2C\\_HAL\\_MasterReadByteBlocking](#) (LPI2C\_Type \*base)  
*Waits until there is a receive ready flag and reads one byte from the receive FIFO.*
- bool [LPI2C\\_HAL\\_MasterWriteByteBlocking](#) (LPI2C\_Type \*base, uint8\_t byte)  
*Waits till a transmit request flag is set and writes one byte of data to the transmit FIFO, then waits till that byte is transferred successfully.*
- [lpi2c\\_status\\_t](#) [LPI2C\\_HAL\\_MasterReceiveDataPolling](#) (LPI2C\_Type \*base, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Performs a polling receive transaction on the LPI2C bus.*
- [lpi2c\\_status\\_t](#) [LPI2C\\_HAL\\_MasterSendDataPolling](#) (LPI2C\_Type \*base, uint16\_t slaveAddr, const uint8\_t \*cmdBuff, uint32\_t cmdSize, const uint8\_t \*txBuff, uint32\_t txSize)  
*Performs a polling send transaction on the LPI2C bus.*
- [lpi2c\\_status\\_t](#) [LPI2C\\_HAL\\_SlaveSendDataPolling](#) (LPI2C\_Type \*base, const uint8\_t \*txBuff, uint32\_t txSize)  
*Sends out multiple bytes of data using the polling method.*
- [lpi2c\\_status\\_t](#) [LPI2C\\_HAL\\_SlaveReceiveDataPolling](#) (LPI2C\_Type \*base, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Receives multiple bytes of data using the polling method.*

## 37.2.4 Enumeration Type Documentation

### 37.2.4.1 enum lpi2c\_status\_t

Enumerator

- kStatus\_LPI2C\_Success* LPI2C operation has no error.
- kStatus\_LPI2C\_Initialized* Current LPI2C is already initialized by one task.
- kStatus\_LPI2C\_Fail* LPI2C operation failed.
- kStatus\_LPI2C\_Busy* The master is already performing a transfer.
- kStatus\_LPI2C\_Timeout* The transfer timed out.
- kStatus\_LPI2C\_ReceivedNak* The slave device sent a NAK in response to a byte.
- kStatus\_LPI2C\_SlaveTxUnderrun* LPI2C Slave TX Underrun error.
- kStatus\_LPI2C\_SlaveRxOverrun* LPI2C Slave RX Overrun error.
- kStatus\_LPI2C\_ArbitrationLost* LPI2C Arbitration Lost error.
- kStatus\_LPI2C\_StopSignalFail* LPI2C STOP signal could not release bus.
- kStatus\_LPI2C\_Idle* LPI2C Slave Bus is Idle.
- kStatus\_LPI2C\_NoReceiveInProgress* Attempt to abort a receiving when no transfer was in progress.
- kStatus\_LPI2C\_NoSendInProgress* Attempt to abort a sending when no transfer was in progress.

## LPI2C HAL driver

**37.2.4.2** enum `lpi2c_master_status_t`

**37.2.4.3** enum `lpi2c_master_interrupt_t`

**37.2.4.4** enum `lpi2c_slave_status_t`

**37.2.4.5** enum `lpi2c_slave_interrupt_t`

**37.2.4.6** enum `lpi2c_direction_t`

Enumerator

*kLPI2CWrite* Master transmit. Master receive.

## 37.2.5 Function Documentation

**37.2.5.1** void `LPI2C_HAL_Init ( LPI2C_Type * base )`

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

**37.2.5.2** static void `LPI2C_HAL_SetMasterCmd ( LPI2C_Type * base, bool enable )`  
**[inline], [static]**

Parameters

|               |                                                         |
|---------------|---------------------------------------------------------|
| <i>base</i>   | The LPI2C peripheral base pointer                       |
| <i>enable</i> | Enable(true) or disable(false) current LPI2C as master. |

**37.2.5.3** static void `LPI2C_HAL_SetSlaveCmd ( LPI2C_Type * base, bool enable )`  
**[inline], [static]**

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

|               |                                                        |
|---------------|--------------------------------------------------------|
| <i>enable</i> | Enable(true) or disable(false) current LPI2C as slave. |
|---------------|--------------------------------------------------------|

**37.2.5.4 static bool LPI2C\_HAL\_MasterGetStatus ( LPI2C\_Type \* *base*, lpi2c\_master\_status\_t *statusFlag* ) [inline], [static]**

Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| <i>base</i>       | The LPI2C peripheral base pointer.                    |
| <i>statusFlag</i> | The status flag, defined in type lpi2c_status_flag_t. |

Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

**37.2.5.5 static void LPI2C\_HAL\_MasterClearStatus ( LPI2C\_Type \* *base*, lpi2c\_master\_status\_t *statusFlag* ) [inline], [static]**

Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| <i>base</i>       | The LPI2C peripheral base pointer.                    |
| <i>statusFlag</i> | The status flag, defined in type lpi2c_status_flag_t. |

**37.2.5.6 static bool LPI2C\_HAL\_SlaveGetStatus ( LPI2C\_Type \* *base*, lpi2c\_slave\_status\_t *statusFlag* ) [inline], [static]**

Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| <i>base</i>       | The LPI2C peripheral base pointer.                    |
| <i>statusFlag</i> | The status flag, defined in type lpi2c_status_flag_t. |

Returns

State of the status flag: asserted (true) or not-asserted (false).

- true: related status flag is being set.
- false: related status flag is not set.

---

## LPI2C HAL driver

**37.2.5.7** `static void LPI2C_HAL_SlaveClearStatus ( LPI2C_Type * base,  
lpi2c_slave_status_t statusFlag ) [inline], [static]`

Parameters

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <i>base</i>       | The LPI2C peripheral base pointer.                                  |
| <i>statusFlag</i> | The status flag, defined in type <code>lpi2c_status_flag_t</code> . |

### 37.2.5.8 void LPI2C\_HAL\_MasterSetIntCmd ( LPI2C\_Type \* *base*, lpi2c\_master\_interrupt\_t *interrupt*, bool *enable* )

This function only enable/disable one specific interrupt. If you need to enable/disable multiple interrupt in one function call, it's better to use the entire register write operation.

Parameters

|                  |                                                  |
|------------------|--------------------------------------------------|
| <i>base</i>      | The LPI2C peripheral base pointer                |
| <i>interrupt</i> | Interrupt name.                                  |
| <i>enable</i>    | Pass true to enable interrupt, false to disable. |

### 37.2.5.9 static bool LPI2C\_HAL\_MasterGetIntCmd ( LPI2C\_Type \* *base*, lpi2c\_master\_interrupt\_t *interrupt* ) [inline], [static]

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

Returns

Whether LPI2C master interrupts are enabled(true) or not(false).

### 37.2.5.10 void LPI2C\_HAL\_SlaveSetIntCmd ( LPI2C\_Type \* *base*, lpi2c\_slave\_interrupt\_t *interrupt*, bool *enable* )

This function only enables/disables one specific interrupt. To enable/disable multiple interrupts in one function call, use the entire register write operation.

Parameters

---

## LPI2C HAL driver

|                  |                                                  |
|------------------|--------------------------------------------------|
| <i>base</i>      | The LPI2C peripheral base pointer                |
| <i>interrupt</i> | Interrupt name.                                  |
| <i>enable</i>    | Pass true to enable interrupt, false to disable. |

**37.2.5.11** `static bool LPI2C_HAL_SlaveGetIntCmd ( LPI2C_Type * base,  
lpi2c_slave_interrupt_t interrupt ) [inline], [static]`

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

Returns

Whether LPI2C slave interrupts are enabled.

**37.2.5.12** `void LPI2C_HAL_SetBaudRate ( LPI2C_Type * base, uint32_t sourceClockInHz,  
uint32_t kbps )`

Parameters

|                        |                                                                            |
|------------------------|----------------------------------------------------------------------------|
| <i>base</i>            | The LPI2C peripheral base pointer                                          |
| <i>sourceClockInHz</i> | LPI2C source input clock in Hertz                                          |
| <i>kbps</i>            | Requested bus frequency in kilohertz. Common values are either 100 or 400. |

**37.2.5.13** `void LPI2C_HAL_SendStart ( LPI2C_Type * base, uint8_t address,  
lpi2c_direction_t dir )`

This function initiates a new master mode transfer by sending the start signal. It is also sends a repeated start signal when a transfer is already in progress.

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

|                |                                               |
|----------------|-----------------------------------------------|
| <i>address</i> | 7-bit slave device address.                   |
| <i>dir</i>     | Master transfer directions(transmit/receive). |

#### 37.2.5.14 `lpi2c_status_t LPI2C_HAL_SendStop ( LPI2C_Type * base )`

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

Returns

Whether the sending of STOP single is success or not.

#### 37.2.5.15 `static void LPI2C_HAL_SlaveSendAck ( LPI2C_Type * base ) [inline], [static]`

This function specifies that an ACK signal is sent in response to the next received byte.

Note that the behaviour of this function is changed when the LPI2C peripheral is placed in the fast ACK mode. In this case, this function causes an ACK signal to be sent in response to the current byte, rather than the next received byte.

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

#### 37.2.5.16 `static void LPI2C_HAL_SlaveSendNak ( LPI2C_Type * base ) [inline], [static]`

This function specifies that a NAK signal is sent in response to the next received byte.

Note that the behaviour of this function is changed when the LPI2C peripheral is placed in the fast ACK mode. In this case, this function causes an NAK signal to be sent in response to the current byte, rather than the next received byte.

Parameters

---

## LPI2C HAL driver

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

**37.2.5.17** `static void LPI2C_HAL_MasterSetRxMode ( LPI2C_Type * base, uint8_t rxSize ) [inline], [static]`

### Parameters

|               |                                                  |
|---------------|--------------------------------------------------|
| <i>base</i>   | The LPI2C peripheral base pointer.               |
| <i>rxSize</i> | Initialize receiving " <i>rxSize</i> " of bytes. |

**37.2.5.18** `void LPI2C_HAL_SetAddress7bit ( LPI2C_Type * base, uint8_t address )`

### Parameters

|                |                                           |
|----------------|-------------------------------------------|
| <i>base</i>    | The LPI2C peripheral base pointer         |
| <i>address</i> | The slave address is in the upper 7 bits. |

**37.2.5.19** `void LPI2C_HAL_SetAddress10bit ( LPI2C_Type * base, uint16_t address )`

### Parameters

|                |                                                       |
|----------------|-------------------------------------------------------|
| <i>base</i>    | The LPI2C peripheral base pointer                     |
| <i>address</i> | The 10-bit slave address, in bits [9:0] of the value. |

**37.2.5.20** `static uint8_t LPI2C_HAL_MasterReadByte ( LPI2C_Type * base ) [inline], [static]`

In a master receive mode, calling this function initiates receiving the next byte of data.

### Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

Returns

This function returns the last byte received while the LPI2C module is configured in master receive or slave receive mode.

**37.2.5.21 static void LPI2C\_HAL\_MasterWriteByte ( LPI2C\_Type \* *base*, uint8\_t *byte* ) [inline], [static]**

When this function is called in the master transmit mode, a data transfer is initiated. In slave mode, the same function is available after an address match occurs.

In a master transmit mode, the first byte of data written following the start bit or repeated start bit is used for the address transfer and must consist of the slave address (in bits 7-1) concatenated with the required R/#W bit (in position bit 0).

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.      |

**37.2.5.22 static uint8\_t LPI2C\_HAL\_SlaveReadByte ( LPI2C\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

Returns

This function returns the last byte received while the LPI2C module is configured in slave receive mode.

**37.2.5.23 static void LPI2C\_HAL\_SlaveWriteByte ( LPI2C\_Type \* *base*, uint8\_t *byte* ) [inline], [static]**

## LPI2C HAL driver

### Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.      |

### 37.2.5.24 `bool LPI2C_HAL_SlaveWriteByteBlocking ( LPI2C_Type * base, uint8_t byte )`

### Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.      |

### Returns

Whether ACK is received(TRUE) or not(FALSE).

### 37.2.5.25 `uint8_t LPI2C_HAL_MasterReadByteBlocking ( LPI2C_Type * base )`

### Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer |
|-------------|-----------------------------------|

### Returns

Returns the last byte received

### 37.2.5.26 `bool LPI2C_HAL_MasterWriteByteBlocking ( LPI2C_Type * base, uint8_t byte )`

### Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPI2C peripheral base pointer. |
| <i>byte</i> | The byte of data to transmit.      |

### Returns

Whether ACK is received(TRUE) or not(FALSE).

### 37.2.5.27 `lpi2c_status_t LPI2C_HAL_MasterReceiveDataPolling ( LPI2C_Type * base, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize )`

## Parameters

|                  |                                                        |
|------------------|--------------------------------------------------------|
| <i>base</i>      | The LPI2C peripheral base pointer.                     |
| <i>salveAddr</i> | The slave address to communicate.                      |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred.         |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred. |
| <i>rxBuff</i>    | The pointer to the data to be transferred.             |
| <i>rxSize</i>    | The length in bytes of the data to be transferred.     |

## Returns

Error or success status returned by API.

**37.2.5.28** `lpi2c_status_t LPI2C_HAL_MasterSendDataPolling ( LPI2C_Type * base,  
uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, const uint8_t *  
txBuff, uint32_t txSize )`

## Parameters

|                  |                                                        |
|------------------|--------------------------------------------------------|
| <i>base</i>      | The LPI2C peripheral base pointer.                     |
| <i>salveAddr</i> | The slave address to communicate.                      |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred.         |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred. |
| <i>txBuff</i>    | The pointer to the data to be transferred.             |
| <i>txSize</i>    | The length in bytes of the data to be transferred.     |

## Returns

Error or success status returned by API.

**37.2.5.29** `lpi2c_status_t LPI2C_HAL_SlaveSendDataPolling ( LPI2C_Type * base, const  
uint8_t * txBuff, uint32_t txSize )`

## LPI2C HAL driver

### Parameters

|               |                                                     |
|---------------|-----------------------------------------------------|
| <i>base</i>   | LPI2C module base pointer.                          |
| <i>txBuff</i> | The buffer pointer which saves the data to be sent. |
| <i>txSize</i> | Size of data to be sent in unit of byte.            |

### Returns

Error or success status returned by API.

### 37.2.5.30 `lpi2c_status_t` LPI2C\_HAL\_SlaveReceiveDataPolling ( `LPI2C_Type` \* *base*, `uint8_t` \* *rxBuff*, `uint32_t` *rxSize* )

### Parameters

|               |                                                         |
|---------------|---------------------------------------------------------|
| <i>base</i>   | LPI2C module base pointer.                              |
| <i>rxBuff</i> | The buffer pointer which saves the data to be received. |
| <i>rxSize</i> | Size of data need to be received in unit of byte.       |

### Returns

Error or success status returned by API.

## 37.3 LPI2C Master peripheral

### 37.3.1 Overview

This section describes the programming interface of the I2C master mode Peripheral driver. The I2C master Peripheral driver provides functions for a master device to send and receive data.

### 37.3.2 I2C Initialization

To initialize the I2C driver, define an `i2c_master_state_t` type variable and pass it in the `i2c_init`. The variable does not need to have a specific value because the I2C driver only needs the memory associated with the variable. Because all I2C master API functions need the run-time structure, it should be maintained as long as the driver is used.

Because I2C drivers use the `OSA_Delay` from OSA layer, `OSA_Init` must be called before calling I2C transaction API functions. Otherwise, the API functions do not work.

### 37.3.3 I2C Data Transactions

I2C master driver provides these APIs for data transactions:

```
I2C_DRV_MasterSendDataBlocking \n
I2C_DRV_MasterReceiveDataBlocking \n
```

Both of these functions perform a blocking transaction, which means that the function does not return until all data is sent/received OR a time out occurs.

Before calling the API functions, the application should define the slave device with "i2c\_device\_t" type. Note that, if the slave is a 10-bit address, the first 6 bits must be 011110 in binary.

```
typedef struct I2CDevice
{
 uint16_t address; // Slave's 7-bit or 10-bit address. If 10-bit address, the first 6 bits must be
 // 011110 in binary.//
 uint32_t baudRate_kbps; // The baud rate in kbps to use with this slave device.//
} i2c_device_t;
```

If the `baudRate_kbps` inside the `i2c_device_t` object is changed, it is automatically applied to the next send/receive transaction.

## Data Structures

*Performs a polling send transaction on the LPI2C bus.*

### 37.3.4 Data Structure Documentation

#### 37.3.4.1 struct lpi2c\_device\_t

##### Data Fields

- uint16\_t [address](#)  
*Slave's 7-bit or 10-bit address.*
- uint32\_t [baudRate\\_kbps](#)  
*The baud rate in kbps to use by current slave device.*

##### 37.3.4.1.0.137 Field Documentation

###### 37.3.4.1.0.137.1 uint16\_t lpi2c\_device\_t::address

If 10-bit address, the first 6 bits must be 011110 in binary.

#### 37.3.4.2 struct lpi2c\_master\_state\_t

Note

The contents of this structure are internal to the driver and should not be modified by users. Contents of the structure are subject to change in future releases.

### 37.3.5 Function Documentation

#### 37.3.5.1 lpi2c\_status\_t LPI2C\_DRV\_MasterInit ( uint32\_t *instance*, lpi2c\_master\_state\_t \* *master* )

Parameters

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <i>instance</i> | The LPI2C peripheral instance number.                   |
| <i>master</i>   | The pointer to the LPI2C master driver state structure. |

Returns

Error or success status returned by API.

#### 37.3.5.2 void LPI2C\_DRV\_MasterDeinit ( uint32\_t *instance* )

## LPI2C Master peripheral

Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPI2C peripheral instance number. |
|-----------------|---------------------------------------|

### 37.3.5.3 void LPI2C\_DRV\_MasterSetBaudRate ( uint32\_t *instance*, const lpi2c\_device\_t \* *device* )

Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | The LPI2C peripheral instance number.                  |
| <i>device</i>   | The pointer to the LPI2C device information structure. |

### 37.3.5.4 lpi2c\_status\_t LPI2C\_DRV\_MasterSendDataBlocking ( uint32\_t *instance*, const lpi2c\_device\_t \* *device*, const uint8\_t \* *cmdBuff*, uint32\_t *cmdSize*, const uint8\_t \* *txBuff*, uint32\_t *txSize*, uint32\_t *timeout\_ms* )

Both *cmdBuff* and *txBuff* are byte-aligned. If slave devices' data is not byte-aligned, prepare these buffers according to the related protocol.

Parameters

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <i>instance</i>   | The LPI2C peripheral instance number.                              |
| <i>device</i>     | The pointer to the LPI2C device information structure.             |
| <i>cmdBuff</i>    | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>    | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>     | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>     | The length in bytes of the data to be transferred, cannot be 0.    |
| <i>timeout_ms</i> | A timeout for the transfer in microseconds.                        |

Returns

Error or success status returned by API.

### 37.3.5.5 lpi2c\_status\_t LPI2C\_DRV\_MasterSendData ( uint32\_t *instance*, const lpi2c\_device\_t \* *device*, const uint8\_t \* *cmdBuff*, uint32\_t *cmdSize*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )

This function returns immediately when setting the buffer pointer and length to transfer buffer and transfer size. Check the status of LPI2C to find out whether the transmission is complete or not. Both *cmdBuff*

and txBuff are byte aligned. If slave devices' data is not byte-aligned, prepare these buffers according to the related protocol.

## LPI2C Master peripheral

### Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPI2C peripheral instance number.                              |
| <i>device</i>   | The pointer to the LPI2C device information structure.             |
| <i>cmdBuff</i>  | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>  | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>   | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>   | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

### 37.3.5.6 `lpi2c_status_t` LPI2C\_DRV\_MasterGetSendStatus ( `uint32_t instance`, `uint32_t * bytesRemaining` )

This function gets the current LPI2C status of the non-blocking transmission.

### Parameters

|                        |                                                              |
|------------------------|--------------------------------------------------------------|
| <i>instance</i>        | Instance number of the LPI2C module.                         |
| <i>bytes-Remaining</i> | The number of remaining bytes in the active LPI2C transmits. |

### Returns

Current status of LPI2C transmission: in progress (busy) or complete (success).

### 37.3.5.7 `lpi2c_status_t` LPI2C\_DRV\_MasterAbortSendData ( `uint32_t instance` )

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module. |
|-----------------|--------------------------------------|

### Returns

Whether the aborting is success or not.

**37.3.5.8** `lpi2c_status_t LPI2C_DRV_MasterReceiveDataBlocking ( uint32_t instance,  
const lpi2c_device_t * device, const uint8_t * cmdBuff, uint32_t cmdSize,  
uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout_ms )`

Both `cmdBuff` and `rxBuff` are byte aligned. If slave devices are not byte-aligned, prepare these buffers according to the related protocol.

## LPI2C Master peripheral

### Parameters

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <i>instance</i>   | The LPI2C peripheral instance number.                              |
| <i>device</i>     | The pointer to the LPI2C device information structure.             |
| <i>cmdBuff</i>    | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>    | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>     | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>     | The length in bytes of the data to be transferred, cannot be 0.    |
| <i>timeout_ms</i> | A timeout for the transfer in microseconds.                        |

### Returns

Error or success status returned by API.

#### 37.3.5.9 `lpi2c_status_t LPI2C_DRV_MasterReceiveData ( uint32_t instance, const lpi2c_device_t * device, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize )`

This function returns immediately after setting the buffer pointer and length to the receive buffer and the receive size. Check the status of LPI2C to find out whether the receive is complete or not. Both `cmdBuff` and `rxBuff` are byte aligned. If slave devices' data is not byte-aligned, prepare these buffers according to the related protocol.

### Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPI2C peripheral instance number.                              |
| <i>device</i>   | The pointer to the LPI2C device information structure.             |
| <i>cmdBuff</i>  | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>  | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>   | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>   | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

#### 37.3.5.10 `lpi2c_status_t LPI2C_DRV_MasterGetReceiveStatus ( uint32_t instance, uint32_t * bytesRemaining )`

This function is designed to get the current LPI2C status of a non-blocking receive.

### Parameters

|                        |                                                              |
|------------------------|--------------------------------------------------------------|
| <i>instance</i>        | Instance number of the LPI2C module.                         |
| <i>bytes-Remaining</i> | The number of remaining bytes in the active LPI2C transmits. |

### Returns

Current status of LPI2C receive: in progress (busy) or complete (success).

**37.3.5.11** `static lpi2c_status_t LPI2C_DRV_MasterReceiveDataPolling ( uint32_t instance, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, uint8_t * rxBuff, uint32_t rxSize ) [inline], [static]`

Both cmdBuff and rxBuff are byte aligned. If the slave device data is not byte-aligned, prepare these buffers according to the related protocol.

### Parameters

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>instance</i>  | Instance number of the LPI2C module.                               |
| <i>slaveAddr</i> | The slave address to communicate.                                  |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred, could be 0. |
| <i>rxBuff</i>    | The pointer to the data to be transferred, cannot be NULL.         |
| <i>rxSize</i>    | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

**37.3.5.12** `static lpi2c_status_t LPI2C_DRV_MasterSendDataPolling ( uint32_t instance, uint16_t slaveAddr, const uint8_t * cmdBuff, uint32_t cmdSize, const uint8_t * txBuff, uint32_t txSize ) [inline], [static]`

Both cmdBuff and txBuff are byte aligned. If the slave device data is not byte-aligned, prepare these buffers according to the related protocol .

## LPI2C Master peripheral

### Parameters

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>instance</i>  | Instance number of the LPI2C module.                               |
| <i>slaveAddr</i> | The slave address to communicate.                                  |
| <i>cmdBuff</i>   | The pointer to the commands to be transferred, could be NULL.      |
| <i>cmdSize</i>   | The length in bytes of the commands to be transferred, could be 0. |
| <i>txBuff</i>    | The pointer to the data to be transferred, cannot be NULL.         |
| <i>txSize</i>    | The length in bytes of the data to be transferred, cannot be 0.    |

### Returns

Error or success status returned by API.

## 37.3.6 Variable Documentation

### 37.3.6.1 LPI2C\_Type\* const g\_lpi2cBase[LPI2C\_INSTANCE\_COUNT]

## 37.4 LPI2C Slave peripheral driver

### 37.4.1 Overview

This section describes the programming interface of the I2C slave mode Peripheral driver.

#### Data Structures

- struct [lpi2c\\_slave\\_state\\_t](#)  
*Runtime state of the LPI2C Slave driver. [More...](#)*
- struct [lpi2c\\_slave\\_user\\_config\\_t](#)  
*Defines the structure to initialize the LPI2C Slave module. [More...](#)*

#### Typedefs

- typedef void(\* [lpi2c\\_slave\\_callback\\_t](#) )(uint8\_t instance, [lpi2c\\_slave\\_event\\_t](#) slaveEvent, void \*userData)  
*LPI2C slave callback function.*

#### Enumerations

- enum [lpi2c\\_slave\\_event\\_t](#) {  
[kLPI2CSlaveTxReq](#) = 0x02u,  
[kLPI2CSlaveRxReq](#) = 0x04u,  
[kLPI2CSlaveTxNAK](#) = 0x08u,  
[kLPI2CSlaveTxEmpty](#) = 0x10u,  
[kLPI2CSlaveRxFull](#) = 0x20u,  
[kLPI2CSlaveAbort](#) = 0x40u }  
*Internal driver state information.*

#### Variables

- LPI2C\_Type \*const [g\\_lpi2cBase](#) [LPI2C\_INSTANCE\_COUNT]  
*Table of base addresses for LPI2C instances.*

#### LPI2C Slave

- void [LPI2C\\_DRV\\_SlaveInit](#) (uint32\_t instance, const [lpi2c\\_slave\\_user\\_config\\_t](#) \*userConfigPtr, [lpi2c\\_slave\\_state\\_t](#) \*slave)  
*Initializes the LPI2C module.*
- void [LPI2C\\_DRV\\_SlaveDeinit](#) (uint32\_t instance)  
*Shuts down the LPI2C slave driver.*
- [lpi2c\\_slave\\_state\\_t](#) \* [LPI2C\\_DRV\\_SlaveGetHandler](#) (uint32\_t instance)

## LPI2C Slave peripheral driver

- Gets the LPI2C slave run-time state structure.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveSendData](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)

*Sends/transmits data by using a non-blocking method.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveSendDataBlocking](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize, uint32\_t timeout\_ms)

*Sends (transmits) data by using a blocking method.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveReceiveData](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)

*Receives the data by using a non-blocking method.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveReceiveDataBlocking](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize, uint32\_t timeout\_ms)

*Receives data by using a blocking method.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveGetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)

*Gets the current status of the LPI2C slave driver.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveGetTransmitStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)

*Gets the current status of the LPI2C slave driver.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveAbortReceiveData](#) (uint32\_t instance, uint32\_t \*rxSize)

*Terminates a non-blocking receive of the LPI2C slave early.*

  - [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveAbortSendData](#) (uint32\_t instance, uint32\_t \*txSize)

*Terminates a non-blocking send of the LPI2C slave early.*

  - static bool [LPI2C\\_DRV\\_SlaveIsBusBusy](#) (uint32\_t instance)

*Gets the current status of the LPI2C slave bus.*

  - static [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveSendDataPolling](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)

*Sends out multiple bytes of data using a polling method.*

  - static [lpi2c\\_status\\_t LPI2C\\_DRV\\_SlaveReceiveDataPolling](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)

*Receives multiple bytes of data using a polling method.*

### 37.4.2 Data Structure Documentation

#### 37.4.2.1 struct lpi2c\_slave\_state\_t

This structure holds data used by the LPI2C Slave Peripheral driver to communicate between the transfer function and the interrupt handler. The interrupt handler also uses this information to keep track of its progress.

#### Data Fields

- [lpi2c\\_status\\_t status](#)  
*The slave LPI2C status.*
- volatile uint32\_t [txSize](#)  
*Size of the transmit buffer.*
- volatile uint32\_t [rxSize](#)  
*Size of the receive buffer.*
- const uint8\_t \* [txBuff](#)  
*Pointer to transmit Buffer.*

- `uint8_t * rxBuff`  
*Pointer to receive Buffer.*
- `bool isTxBusy`  
*True if the driver is sending data.*
- `bool isRxBusy`  
*True if the driver is receiving data.*
- `bool isTxBlocking`  
*True if transmit is blocking transaction.*
- `bool isRxBlocking`  
*True if receive is blocking transaction.*
- `event_t irqEvent`  
*Use to wait for ISR to complete transmit and receive.*
- `bool slaveListening`  
*True if slave is in listening mode.*
- `lpi2c_slave_callback_t slaveCallback`  
*Pointer to user callback function.*
- `void * callbackParam`  
*Pointer to user callback parameter.*

- 37.4.2.2** `struct lpi2c_slave_user_config_t`

## LPI2C Slave peripheral driver

### Note

once slaveListening mode is selected, all send/receive blocking/non-blocking functions will be invalid.

### Data Fields

- uint16\_t **address**  
*Slave's 7-bit or 10-bit address.*
- bool **slaveListening**  
*The slave configuration mode.*
- lpi2c\_slave\_callback\_t **slaveCallback**  
*The slave callback function.*
- void \* **callbackParam**  
*The slave callback data.*

### 37.4.2.2.0.139 Field Documentation

#### 37.4.2.2.0.139.1 uint16\_t lpi2c\_slave\_user\_config\_t::address

If 10-bit address, the first 6 bits must be 011110 in binary.

## 37.4.3 Enumeration Type Documentation

### 37.4.3.1 enum lpi2c\_slave\_event\_t

#### Note

The contents of this structure are internal to the driver and should not be modified by users. Also, contents of the structure are subject to change in future releases.

Defines the type of flags for callback function

#### Enumerator

- kLPI2CSlaveTxReq*** The slave LPI2C Transmitting Request event.
- kLPI2CSlaveRxReq*** The slave LPI2C Receiving Request event.
- kLPI2CSlaveTxNAK*** The slave LPI2C Transmitting NAK event.
- kLPI2CSlaveTxEmpty*** The slave LPI2C Transmitting Buffer Empty event.
- kLPI2CSlaveRxFull*** The slave LPI2C Receiving Buffer Full event.
- kLPI2CSlaveAbort*** The slave LPI2C Slave abort transaction event.

### 37.4.4 Function Documentation

**37.4.4.1 void LPI2C\_DRV\_Slavelnit ( uint32\_t *instance*, const lpi2c\_slave\_user\_config\_t \* *userConfigPtr*, lpi2c\_slave\_state\_t \* *slave* )**

Saves the application callback info, turns on the clock to the module, enables the device, and enables interrupts. Sets the LPI2C to slave mode. IOMUX should be handled in the `init_hardware()` function.

## LPI2C Slave peripheral driver

### Parameters

|                      |                                             |
|----------------------|---------------------------------------------|
| <i>instance</i>      | Instance number of the LPI2C module.        |
| <i>userConfigPtr</i> | Pointer of the user configuration structure |
| <i>slave</i>         | Pointer of the slave run-time structure.    |

### 37.4.4.2 void LPI2C\_DRV\_SlaveDeinit ( uint32\_t *instance* )

Clears the control register and turns off the clock to the module.

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module. |
|-----------------|--------------------------------------|

### 37.4.4.3 lpi2c\_slave\_state\_t\* LPI2C\_DRV\_SlaveGetHandler ( uint32\_t *instance* )

This function gets the LPI2C slave run-time state structure.

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module. |
|-----------------|--------------------------------------|

### Returns

Pointer to LPI2C slave run-time state structure.

### 37.4.4.4 lpi2c\_status\_t LPI2C\_DRV\_SlaveSendData ( uint32\_t *instance*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )

This function returns immediately when the buffer pointer and length are set to the transfer buffer and transfer size. Check the status of LPI2C slave to find out whether the transmission is complete. Wait the kLPI2CSlaveStop or the kLPI2CSlaveTxDone to ensure that the transmission is ended.

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module. |
|-----------------|--------------------------------------|

|               |                                                   |
|---------------|---------------------------------------------------|
| <i>txBuff</i> | The pointer to sending the data buffer.           |
| <i>txSize</i> | The number of bytes which the user wants to send. |

Returns

success (if LPI2C slave status is not error) or error code in others.

### 37.4.4.5 `lpi2c_status_t LPI2C_DRV_SlaveSendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout_ms )`

This function sets the buffer pointer and length to the transfer buffer and the transfer size and waits until the transmission is ended (NAK is detected).

Parameters

|                   |                                                                   |
|-------------------|-------------------------------------------------------------------|
| <i>instance</i>   | Instance number of the LPI2C module.                              |
| <i>txBuff</i>     | The pointer to sending the data buffer.                           |
| <i>txSize</i>     | The number of bytes which the user wants to send.                 |
| <i>timeout_ms</i> | The maximum number of milliseconds to wait for transmit completed |

Returns

success (if LPI2C slave status is not error) or error code in others.

### 37.4.4.6 `lpi2c_status_t LPI2C_DRV_SlaveReceiveData ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize )`

This function returns immediately when the buffer pointer and length are set to the receive buffer and the receive size. Check the status of the LPI2C slave to find out whether the transmission is completed. Wait the `kLPI2CSlaveStop` or the `kLPI2CSlaveRxDone` to ensure that the transmission is ended.

Parameters

|                 |                                          |
|-----------------|------------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module.     |
| <i>rxBuff</i>   | The pointer to the received data buffer. |

## LPI2C Slave peripheral driver

|               |                                                      |
|---------------|------------------------------------------------------|
| <i>rxSize</i> | The number of bytes which the user wants to receive. |
|---------------|------------------------------------------------------|

Returns

success (if LPI2C slave status is not error) or error code in others.

### 37.4.4.7 `lpi2c_status_t LPI2C_DRV_SlaveReceiveDataBlocking ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout_ms )`

This function sets the buffer pointer and length to the receive buffer and the receive size. Then, the function waits until the transmission has ended (all data is received or a STOP signal is detected).

Parameters

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| <i>instance</i>   | Instance number of the LPI2C module.                             |
| <i>rxBuff</i>     | The pointer to the received data buffer.                         |
| <i>rxSize</i>     | The number of bytes which the user wants to receive.             |
| <i>timeout_ms</i> | The maximum number of milliseconds to wait for receive completed |

Returns

success (if LPI2C slave status is not error) or error code in others.

### 37.4.4.8 `lpi2c_status_t LPI2C_DRV_SlaveGetReceiveStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                     |
|------------------------|-----------------------------------------------------|
| <i>instance</i>        | Instance number of the LPI2C module.                |
| <i>bytes-Remaining</i> | The number of remaining bytes that LPI2C transmits. |

Returns

The current status of LPI2C instance: in progress (busy), complete (success) or idle (lpi2c bus is idle).

### 37.4.4.9 `lpi2c_status_t LPI2C_DRV_SlaveGetTransmitStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                     |
|------------------------|-----------------------------------------------------|
| <i>instance</i>        | Instance number of the LPI2C module.                |
| <i>bytes-Remaining</i> | The number of remaining bytes that LPI2C transmits. |

Returns

The current status of LPI2C instance: in progress (busy), complete (success) or idle (LPI2C bus is idle).

**37.4.4.10 `lpi2c_status_t LPI2C_DRV_SlaveAbortReceiveData ( uint32_t instance, uint32_t * rxSize )`**

During an non-blocking receiving

Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module.                   |
| <i>rxSize</i>   | The number of remaining bytes in LPI2C receive buffer. |

Returns

kStatus\_LPI2C\_Success if success kStatus\_LPI2C\_NoReceiveInProgress if none receiving is available.

**37.4.4.11 `lpi2c_status_t LPI2C_DRV_SlaveAbortSendData ( uint32_t instance, uint32_t * txSize )`**

During an non-blocking receiving

Parameters

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module.              |
| <i>txSize</i>   | The number of remaining bytes in LPI2C Tx Buffer. |

Returns

kStatus\_LPI2C\_Success if success kStatus\_LPI2C\_NoReceiveInProgress if none receiving is available.

**37.4.4.12 `static bool LPI2C_DRV_SlavelBusBusy ( uint32_t instance ) [inline], [static]`**

## LPI2C Slave peripheral driver

### Parameters

|                 |                                      |
|-----------------|--------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module. |
|-----------------|--------------------------------------|

### Returns

True if the bus is busy False if the bus is idle

**37.4.4.13** `static lpi2c_status_t LPI2C_DRV_SlaveSendDataPolling ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize ) [inline], [static]`

### Parameters

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module.                |
| <i>txBuff</i>   | The buffer pointer which saves the data to be sent. |
| <i>txSize</i>   | Size of data to be sent in bytes.                   |

### Returns

Error or success status returned by API.

**37.4.4.14** `static lpi2c_status_t LPI2C_DRV_SlaveReceiveDataPolling ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize ) [inline], [static]`

### Parameters

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <i>instance</i> | Instance number of the LPI2C module.                    |
| <i>rxBuff</i>   | The buffer pointer which saves the data to be received. |
| <i>rxSize</i>   | Size of data need to be received in bytes.              |

### Returns

Error or success status returned by the API.

## 37.4.5 Variable Documentation

**37.4.5.1** `LPI2C_Type* const g_lpi2cBase[LPI2C_INSTANCE_COUNT]`

## Chapter 38

# Low Power Serial Communication Interface (LPSCI)

### 38.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Universal Asynchronous Receiver/-Transmitter (LPSCI) block of Kinetis devices.

#### Modules

- [LPSCI HAL driver](#)
- [LPSCI Peripheral driver](#)

## LPSCI HAL driver

### 38.2 LPSCI HAL driver

#### 38.2.1 Overview

The section describes the programming interface of the LPSCI HAL driver.

#### Files

- file [fsl\\_lpsci\\_hal.h](#)

#### Enumerations

- enum [lpsci\\_status\\_t](#)  
*Error codes for the LPSCI driver.*
- enum [lpsci\\_stop\\_bit\\_count\\_t](#) {  
[kLpsciOneStopBit](#) = 0U,  
[kLpsciTwoStopBit](#) = 1U }  
*LPSCI number of stop bits.*
- enum [lpsci\\_parity\\_mode\\_t](#) {  
[kLpsciParityDisabled](#) = 0x0U,  
[kLpsciParityEven](#) = 0x2U,  
[kLpsciParityOdd](#) = 0x3U }  
*LPSCI parity mode.*
- enum [lpsci\\_bit\\_count\\_per\\_char\\_t](#) {  
[kLpsci8BitsPerChar](#) = 0U,  
[kLpsci9BitsPerChar](#) = 1U }  
*LPSCI number of bits in a character.*
- enum [lpsci\\_operation\\_config\\_t](#) {  
[kLpsciOperates](#) = 0U,  
[kLpsciStops](#) = 1U }  
*LPSCI operation configuration constants.*
- enum [lpsci\\_receiver\\_source\\_t](#) {  
[kLpsciLoopBack](#) = 0U,  
[kLpsciSingleWire](#) = 1U }  
*LPSCI receiver source select mode.*
- enum [lpsci\\_wakeup\\_method\\_t](#) {  
[kLpsciIdleLineWake](#) = 0U,  
[kLpsciAddrMarkWake](#) = 1U }  
*LPSCI wakeup from standby method constants.*
- enum [lpsci\\_idle\\_line\\_select\\_t](#) {  
[kLpsciIdleLineAfterStartBit](#) = 0U,  
[kLpsciIdleLineAfterStopBit](#) = 1U }  
*LPSCI idle-line detect selection types.*
- enum [lpsci\\_break\\_char\\_length\\_t](#) {  
[kLpsciBreakChar10BitMinimum](#) = 0U,  
[kLpsciBreakChar13BitMinimum](#) = 1U }

- LPSCI break character length settings for transmit/detect.*

  - enum `lpsci_singlewire_txdir_t` {  
`kLpsciSinglewireTxdirIn` = 0U,  
`kLpsciSinglewireTxdirOut` = 1U }

*LPSCI single-wire mode transmit direction.*
- enum `lpsci_ir_tx_pulsewidth_t` {  
`kLpsciIrThreeSixteenthsWidth` = 0U,  
`kLpsciIrOneSixteenthWidth` = 1U,  
`kLpsciIrOneThirtiethWidth` = 2U,  
`kLpsciIrOneFourthWidth` = 3U }

*LPSCI infrared transmitter pulse width options.*
- enum `lpsci_status_flag_t` {  
`kLpsciTxDataRegEmpty` = 0U << LPSCI\_SHIFT | UART0\_S1\_TDRE\_SHIFT,  
`kLpsciTxComplete` = 0U << LPSCI\_SHIFT | UART0\_S1\_TC\_SHIFT,  
`kLpsciRxDataRegFull` = 0U << LPSCI\_SHIFT | UART0\_S1\_RDRF\_SHIFT,  
`kLpsciIdleLineDetect` = 0U << LPSCI\_SHIFT | UART0\_S1\_IDLE\_SHIFT,  
`kLpsciRxOverrun` = 0U << LPSCI\_SHIFT | UART0\_S1\_OR\_SHIFT,  
`kLpsciNoiseDetect` = 0U << LPSCI\_SHIFT | UART0\_S1\_NF\_SHIFT,

`kLpsciParityErr` = 0U << LPSCI\_SHIFT | UART0\_S1\_PF\_SHIFT,  
`kLpsciLineBreakDetect` = 1U << LPSCI\_SHIFT | UART0\_S2\_LBKDIF\_SHIFT,  
`kLpsciRxActiveEdgeDetect` = 1U << LPSCI\_SHIFT | UART0\_S2\_RXEDGIF\_SHIFT,  
`kLpsciRxActive` = 1U << LPSCI\_SHIFT | UART0\_S2\_RAF\_SHIFT }

*LPSCI status flags.*
- enum `lpsci_interrupt_t` {  
`kLpsciIntLinBreakDetect` = 0U << LPSCI\_SHIFT | UART0\_BDH\_LBKDIE\_SHIFT,  
`kLpsciIntRxActiveEdge` = 0U << LPSCI\_SHIFT | UART0\_BDH\_RXEDGIE\_SHIFT,  
`kLpsciIntTxDataRegEmpty` = 1U << LPSCI\_SHIFT | UART0\_C2\_TIE\_SHIFT,  
`kLpsciIntTxComplete` = 1U << LPSCI\_SHIFT | UART0\_C2\_TCIE\_SHIFT,  
`kLpsciIntRxDataRegFull` = 1U << LPSCI\_SHIFT | UART0\_C2\_RIE\_SHIFT,  
`kLpsciIntIdleLine` = 1U << LPSCI\_SHIFT | UART0\_C2\_ILIE\_SHIFT,  
`kLpsciIntRxOverrun` = 2U << LPSCI\_SHIFT | UART0\_C3\_ORIE\_SHIFT,  
`kLpsciIntNoiseErrFlag` = 2U << LPSCI\_SHIFT | UART0\_C3\_NEIE\_SHIFT,  
`kLpsciIntFrameErrFlag` = 2U << LPSCI\_SHIFT | UART0\_C3\_FEIE\_SHIFT,  
`kLpsciIntParityErrFlag` = 2U << LPSCI\_SHIFT | UART0\_C3\_PEIE\_SHIFT }

*LPSCI interrupt configuration structure; default settings are 0 (disabled).*

## LPSCI Common Configurations

- void `LPSCI_HAL_Init` (UART0\_Type \*base)  
*Initializes the LPSCI controller.*
- static void `LPSCI_HAL_EnableTransmitter` (UART0\_Type \*base)  
*Enables the LPSCI transmitter.*
- static void `LPSCI_HAL_DisableTransmitter` (UART0\_Type \*base)  
*Disables the LPSCI transmitter.*
- static bool `LPSCI_HAL_IsTransmitterEnabled` (UART0\_Type \*base)

## LPSCI HAL driver

- Gets the LPSCI transmitter enabled/disabled configuration setting.*

  - static void [LPSCI\\_HAL\\_EnableReceiver](#) (UART0\_Type \*base)

*Enables the LPSCI receiver.*
- static void [LPSCI\\_HAL\\_DisableReceiver](#) (UART0\_Type \*base)

*Disables the LPSCI receiver.*
- static bool [LPSCI\\_HAL\\_IsReceiverEnabled](#) (UART0\_Type \*base)

*Gets the LPSCI receiver enabled/disabled configuration setting.*
- [lpsci\\_status\\_t](#) [LPSCI\\_HAL\\_SetBaudRate](#) (UART0\_Type \*base, uint32\_t sourceClockInHz, uint32\_t baudRate)

*Configures the LPSCI baud rate.*
- void [LPSCI\\_HAL\\_SetBaudRateDivisor](#) (UART0\_Type \*base, uint16\_t baudRateDivisor)

*Sets the LPSCI baud rate modulo divisor value.*
- static void [LPSCI\\_HAL\\_SetBitCountPerChar](#) (UART0\_Type \*base, [lpsci\\_bit\\_count\\_per\\_char\\_t](#) bitCountPerChar)

*Configures the number of bits per character in the LPSCI controller.*
- void [LPSCI\\_HAL\\_SetParityMode](#) (UART0\_Type \*base, [lpsci\\_parity\\_mode\\_t](#) parityMode)

*Configures the parity mode in the LPSCI controller.*

## LPSCI Interrupts and DMA

- void [LPSCI\\_HAL\\_SetIntMode](#) (UART0\_Type \*base, [lpsci\\_interrupt\\_t](#) interrupt, bool enable)

*Configures the LPSCI module interrupts to enable/disable various interrupt sources.*
- bool [LPSCI\\_HAL\\_GetIntMode](#) (UART0\_Type \*base, [lpsci\\_interrupt\\_t](#) interrupt)

*Returns whether the LPSCI module interrupts are enabled/disabled.*
- static uint32\_t [LPSCI\\_HAL\\_GetDataRegAddr](#) (UART0\_Type \*base)

*Gets the LPSCI transmit/receive data register address.*

## LPSCI Transfer Functions

- static void [LPSCI\\_HAL\\_Putchar](#) (UART0\_Type \*base, uint8\_t data)

*This function allows the user to send an 8-bit character from the LPSCI data register.*
- void [LPSCI\\_HAL\\_Putchar9](#) (UART0\_Type \*base, uint16\_t data)

*This function allows the user to send a 9-bit character from the LPSCI data register.*
- void [LPSCI\\_HAL\\_Putchar10](#) (UART0\_Type \*base, uint16\_t data)

*This function allows the user to send a 10-bit character from the LPSCI data register.*
- static void [LPSCI\\_HAL\\_Getchar](#) (UART0\_Type \*base, uint8\_t \*readData)

*This function gets a received 8-bit character from the LPSCI data register.*
- void [LPSCI\\_HAL\\_Getchar9](#) (UART0\_Type \*base, uint16\_t \*readData)

*This function gets a received 9-bit character from the LPSCI data register.*
- void [LPSCI\\_HAL\\_Getchar10](#) (UART0\_Type \*base, uint16\_t \*readData)

*This function gets a received 10-bit character from the LPSCI data register.*
- void [LPSCI\\_HAL\\_SendDataPolling](#) (UART0\_Type \*base, const uint8\_t \*txBuff, uint32\_t txSize)

*Sends out multiple bytes of data using the polling method.*
- [lpsci\\_status\\_t](#) [LPSCI\\_HAL\\_ReceiveDataPolling](#) (UART0\_Type \*base, uint8\_t \*rxBuff, uint32\_t rxSize)

*Receives multiple bytes of data using the polling method.*

## LPSCI Status Flags

- bool [LPSCI\\_HAL\\_GetStatusFlag](#) (UART0\_Type \*base, [lpsci\\_status\\_flag\\_t](#) statusFlag)  
*Gets all LPSCI status flag states.*
- [lpsci\\_status\\_t LPSCI\\_HAL\\_ClearStatusFlag](#) (UART0\_Type \*base, [lpsci\\_status\\_flag\\_t](#) statusFlag)  
*Clears an individual and specific LPSCI status flag.*

## LPSCI Special Feature Configurations

- static void [LPSCI\\_HAL\\_SetWaitModeOperation](#) (UART0\_Type \*base, [lpsci\\_operation\\_config\\_t](#) mode)  
*Configures the LPSCI to either operate or cease to operate in wait mode.*
- static [lpsci\\_operation\\_config\\_t LPSCI\\_HAL\\_GetWaitModeOperation](#) (UART0\_Type \*base)  
*Determines if the LPSCI operates or ceases to operate in wait mode.*
- static void [LPSCI\\_HAL\\_SetLoopCmd](#) (UART0\_Type \*base, bool enable)  
*Configures the LPSCI loopback operation.*
- static void [LPSCI\\_HAL\\_SetReceiverSource](#) (UART0\_Type \*base, [lpsci\\_receiver\\_source\\_t](#) source)  
*Configures the LPSCI single-wire operation.*
- static void [LPSCI\\_HAL\\_SetTransmitterDir](#) (UART0\_Type \*base, [lpsci\\_singlewire\\_txdir\\_t](#) direction)  
*Configures the LPSCI transmit direction while in single-wire mode.*
- [lpsci\\_status\\_t LPSCI\\_HAL\\_PutReceiverInStandbyMode](#) (UART0\_Type \*base)  
*Places the LPSCI receiver in standby mode.*
- static void [LPSCI\\_HAL\\_PutReceiverInNormalMode](#) (UART0\_Type \*base)  
*Places the LPSCI receiver in normal mode (disable standby mode operation).*
- static bool [LPSCI\\_HAL\\_IsReceiverInStandby](#) (UART0\_Type \*base)  
*Determines if the LPSCI receiver is currently in standby mode.*
- static void [LPSCI\\_HAL\\_SetReceiverWakeupMethod](#) (UART0\_Type \*base, [lpsci\\_wakeup\\_method\\_t](#) method)  
*Selects the LPSCI receiver wakeup method (idle-line or address-mark) from standby mode.*
- static [lpsci\\_wakeup\\_method\\_t LPSCI\\_HAL\\_GetReceiverWakeupMethod](#) (UART0\_Type \*base)  
*Gets the LPSCI receiver wakeup method (idle-line or address-mark) from standby mode.*
- void [LPSCI\\_HAL\\_ConfigIdleLineDetect](#) (UART0\_Type \*base, [uint8\\_t](#) idleLine, [uint8\\_t](#) rxWakeIdleDetect)  
*Configures the operation options of the LPSCI idle line detect.*
- static void [LPSCI\\_HAL\\_SetBreakCharTransmitLength](#) (UART0\_Type \*base, [lpsci\\_break\\_char\\_length\\_t](#) length)  
*Configures the LPSCI break character transmit length.*
- static void [LPSCI\\_HAL\\_SetBreakCharDetectLength](#) (UART0\_Type \*base, [lpsci\\_break\\_char\\_length\\_t](#) length)  
*Configures the LPSCI break character detect length.*
- static void [LPSCI\\_HAL\\_SetBreakCharCmd](#) (UART0\_Type \*base, bool enable)  
*Configures the LPSCI transmit send break character operation.*
- void [LPSCI\\_HAL\\_SetMatchAddress](#) (UART0\_Type \*base, bool matchAddrMode1, bool matchAddrMode2, [uint8\\_t](#) matchAddrValue1, [uint8\\_t](#) matchAddrValue2)  
*Configures the LPSCI match address mode control operation.*

## LPSCI HAL driver

### 38.2.2 Enumeration Type Documentation

#### 38.2.2.1 enum lpsci\_status\_t

#### 38.2.2.2 enum lpsci\_stop\_bit\_count\_t

These constants define the number of allowable stop bits to configure in a LPSCI base.

Enumerator

*kLpSciOneStopBit* one stop bit  
*kLpSciTwoStopBit* two stop bits

#### 38.2.2.3 enum lpsci\_parity\_mode\_t

These constants define the LPSCI parity mode options: disabled or enabled of type even or odd.

Enumerator

*kLpSciParityDisabled* parity disabled  
*kLpSciParityEven* parity enabled, type even, bit setting: PE|PT = 10  
*kLpSciParityOdd* parity enabled, type odd, bit setting: PE|PT = 11

#### 38.2.2.4 enum lpsci\_bit\_count\_per\_char\_t

These constants define the number of allowable data bits per LPSCI character. Note, check the LPSCI documentation to determine if the desired LPSCI base supports the desired number of data bits per LPSCI character.

Enumerator

*kLpSci8BitsPerChar* 8-bit data characters  
*kLpSci9BitsPerChar* 9-bit data characters

#### 38.2.2.5 enum lpsci\_operation\_config\_t

This provides constants for LPSCI operational states: "operates normally" or "stops/ceases operation"

Enumerator

*kLpSciOperates* LPSCI continues to operate normally.  
*kLpSciStops* LPSCI ceases operation.

### 38.2.2.6 enum lpsci\_receiver\_source\_t

Enumerator

- kLpsciLoopBack* Internal loop back mode.
- kLpsciSingleWire* Single wire mode.

### 38.2.2.7 enum lpsci\_wakeup\_method\_t

This provides constants for the two LPSCI wakeup methods: idle-line or address-mark.

Enumerator

- kLpsciIdleLineWake* The idle-line wakes LPSCI receiver from standby.
- kLpsciAddrMarkWake* The address-mark wakes LPSCI receiver from standby.

### 38.2.2.8 enum lpsci\_idle\_line\_select\_t

This provides constants for the LPSCI idle character bit-count start: either after start or stop bit.

Enumerator

- kLpsciIdleLineAfterStartBit* LPSCI idle character bit count start after start bit.
- kLpsciIdleLineAfterStopBit* LPSCI idle character bit count start after stop bit.

### 38.2.2.9 enum lpsci\_break\_char\_length\_t

This provides constants for the LPSCI break character length for both transmission and detection purposes. Note that the actual maximum bit times may vary depending on the LPSCI base.

Enumerator

- kLpsciBreakChar10BitMinimum* LPSCI break char length 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 13 (if M10 = 1, SNBS = 1)
- kLpsciBreakChar13BitMinimum* LPSCI break char length 13 bit times (if M = 0, SBNS = 0) or 14 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 15 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 16 (if M10 = 1, SNBS = 1)

### 38.2.2.10 enum lpsci\_singlewire\_txdir\_t

This provides constants for the LPSCI transmit direction when configured for single-wire mode. The transmit line TXDIR is either an input or output.

## LPSCI HAL driver

Enumerator

*kLpisciSinglewireTxdirIn* LPSCI Single-Wire mode TXDIR input.  
*kLpisciSinglewireTxdirOut* LPSCI Single-Wire mode TXDIR output.

### 38.2.2.11 enum lpisci\_ir\_tx\_pulsewidth\_t

This provides constants for the LPSCI infrared (IR) pulse widths. Options include 3/16, 1/16 1/32, and 1/4 pulse widths.

Enumerator

*kLpisciIrThreeSixteenthsWidth* 3/16 pulse  
*kLpisciIrOneSixteenthWidth* 1/16 pulse  
*kLpisciIrOneThirtysecondsWidth* 1/32 pulse  
*kLpisciIrOneFourthWidth* 1/4 pulse

### 38.2.2.12 enum lpisci\_status\_flag\_t

This provides constants for the LPSCI status flags for use in the LPSCI functions.

Enumerator

*kLpisciTxDataRegEmpty* Transmit data register empty flag, sets when Tx buffer is empty.  
*kLpisciTxComplete* Transmission complete flag, sets when transmission activity complete.  
*kLpisciRxDataRegFull* Receive data register full flag, sets when the receive data buffer is full.  
*kLpisciIdleLineDetect* Idle line detect flag, sets when idle line detected.  
*kLpisciRxOverrun* Rxr Overrun, sets when new data is received before data is read from receive register.  
*kLpisciNoiseDetect* Rxr takes 3 samples of each received bit. If any of these samples differ, noise flag sets  
*kLpisciFrameErr* Frame error flag, sets if logic 0 was detected where stop bit expected.  
*kLpisciParityErr* If parity enabled, sets upon parity error detection.  
*kLpisciLineBreakDetect* LIN break detect interrupt flag, sets when LIN break char detected and LIN circuit enabled.  
*kLpisciRxActiveEdgeDetect* Receive pin active edge interrupt flag, sets when active edge detected.  
*kLpisciRxActive* Receiver Active Flag (RAF), sets at beginning of valid start bit.

### 38.2.2.13 enum lpisci\_interrupt\_t

This structure contains the settings for all LPSCI interrupt configurations.

Enumerator

*kLpisciIntLinBreakDetect* LIN break detect.

- kLpSciIntRxActiveEdge* Receive Active Edge.
- kLpSciIntTxDataRegEmpty* Transmit data register empty.
- kLpSciIntTxComplete* Transmission complete.
- kLpSciIntRxDataRegFull* Receiver data register full.
- kLpSciIntIdleLine* Idle line.
- kLpSciIntRxOverrun* Receiver Overrun.
- kLpSciIntNoiseErrFlag* Noise error flag.
- kLpSciIntFrameErrFlag* Framing error flag.
- kLpSciIntParityErrFlag* Parity error flag.

### 38.2.3 Function Documentation

#### 38.2.3.1 void LPSCI\_HAL\_Init ( UART0\_Type \* base )

This function initializes the module to a known state.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

#### 38.2.3.2 static void LPSCI\_HAL\_EnableTransmitter ( UART0\_Type \* base ) [inline], [static]

This function allows the user to enable the LPSCI transmitter.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

#### 38.2.3.3 static void LPSCI\_HAL\_DisableTransmitter ( UART0\_Type \* base ) [inline], [static]

This function allows the user to disable the LPSCI transmitter.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

## LPSCI HAL driver

**38.2.3.4 static bool LPSCI\_HAL\_IsTransmitterEnabled ( UART0\_Type \* *base* )  
[inline], [static]**

This function allows the user to get the setting of the LPSCI transmitter.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

The state of LPSCI transmitter enable(true)/disable(false) setting.

**38.2.3.5 static void LPSCI\_HAL\_EnableReceiver ( UART0\_Type \* *base* ) [inline],  
[static]**

This function allows the user to enable the LPSCI receiver.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

**38.2.3.6 static void LPSCI\_HAL\_DisableReceiver ( UART0\_Type \* *base* ) [inline],  
[static]**

This function allows the user to disable the LPSCI receiver.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

**38.2.3.7 static bool LPSCI\_HAL\_IsReceiverEnabled ( UART0\_Type \* *base* ) [inline],  
[static]**

This function allows the user to get the setting of the LPSCI receiver.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

The state of LPSCI receiver enable(true)/disable(false) setting.

**38.2.3.8 `lpsci_status_t LPSCI_HAL_SetBaudRate ( UART0_Type * base, uint32_t sourceClockInHz, uint32_t baudRate )`**

This function programs the LPSCI baud rate to the desired value passed in by the user. The user must also pass in the module source clock so that the function can calculate the baud rate divisors to their appropriate values. In some LPSCI bases it is required that the transmitter/receiver be disabled before calling this function. Generally this is applied to all LPSCIs to ensure safe operation.

Parameters

|                         |                                 |
|-------------------------|---------------------------------|
| <i>base</i>             | LPSCI module base pointer.      |
| <i>sourceClockIn-Hz</i> | LPSCI source input clock in Hz. |
| <i>baudRate</i>         | LPSCI desired baud rate.        |

Returns

An error code or `kStatus_LPSCI_Success`

**38.2.3.9 `void LPSCI_HAL_SetBaudRateDivisor ( UART0_Type * base, uint16_t baudRateDivisor )`**

This function allows the user to program the baud rate divisor directly in situations where the divisor value is known. In this case, the user may not want to call the [LPSCI\\_HAL\\_SetBaudRate\(\)](#) function because the divisor is already known.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

## LPSCI HAL driver

|                         |                                            |
|-------------------------|--------------------------------------------|
| <i>baudRate-Divisor</i> | The baud rate modulo division "SBR" value. |
|-------------------------|--------------------------------------------|

**38.2.3.10 static void LPSCI\_HAL\_SetBitCountPerChar ( UART0\_Type \* *base*, lpsci\_bit\_count\_per\_char\_t *bitCountPerChar* ) [inline], [static]**

This function allows the user to configure the number of bits per character according to the typedef lpsci\_bit\_count\_per\_char\_t.

Parameters

|                         |                                                                     |
|-------------------------|---------------------------------------------------------------------|
| <i>base</i>             | LPSCI module base pointer.                                          |
| <i>bitCountPer-Char</i> | Number of bits per char (8, 9, or 10, depending on the LPSCI base). |

**38.2.3.11 void LPSCI\_HAL\_SetParityMode ( UART0\_Type \* *base*, lpsci\_parity\_mode\_t *parityMode* )**

This function allows the user to configure the parity mode of the LPSCI controller to disable or enable it for even parity or odd parity.

Parameters

|                   |                                                                               |
|-------------------|-------------------------------------------------------------------------------|
| <i>base</i>       | LPSCI module base pointer.                                                    |
| <i>parityMode</i> | Parity mode setting (enabled, disable, odd, even - see parity_mode_t struct). |

**38.2.3.12 void LPSCI\_HAL\_SetIntMode ( UART0\_Type \* *base*, lpsci\_interrupt\_t *interrupt*, bool *enable* )**

Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>base</i>      | LPSCI module base pointer.          |
| <i>interrupt</i> | LPSCI interrupt configuration data. |
| <i>enable</i>    | true: enable, false: disable.       |

**38.2.3.13** `bool LPSCI_HAL_GetIntMode ( UART0_Type * base, lpsci_interrupt_t interrupt )`

Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <i>base</i>      | LPSCI module base pointer.          |
| <i>interrupt</i> | LPSCI interrupt configuration data. |

Returns

true: enable, false: disable.

**38.2.3.14** `static uint32_t LPSCI_HAL_GetDataRegAddr ( UART0_Type * base )  
[inline], [static]`

This function is used for DMA transfer.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base address. |
|-------------|----------------------------|

Returns

LPSCI tx/rx data register address.

**38.2.3.15** `static void LPSCI_HAL_Putchar ( UART0_Type * base, uint8_t data )  
[inline], [static]`

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | LPSCI module base pointer.      |
| <i>data</i> | The data to send of size 8-bit. |

## LPSCI HAL driver

**38.2.3.16 void LPSCI\_HAL\_Putchar9 ( UART0\_Type \* *base*, uint16\_t *data* )**

Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>base</i> | LPSCI module base pointer.      |
| <i>data</i> | The data to send of size 9-bit. |

**38.2.3.17 void LPSCI\_HAL\_Putchar10 ( UART0\_Type \* *base*, uint16\_t *data* )**

Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>base</i> | LPSCI module base pointer.       |
| <i>data</i> | The data to send of size 10-bit. |

**38.2.3.18 static void LPSCI\_HAL\_Getchar ( UART0\_Type \* *base*, uint8\_t \* *readData* )  
[inline], [static]**

Parameters

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| <i>base</i>     | LPSCI module base pointer.                               |
| <i>readData</i> | The received data read from data register of size 8-bit. |

**38.2.3.19 void LPSCI\_HAL\_Getchar9 ( UART0\_Type \* *base*, uint16\_t \* *readData* )**

Parameters

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| <i>base</i>     | LPSCI module base pointer.                               |
| <i>readData</i> | The received data read from data register of size 9-bit. |

**38.2.3.20 void LPSCI\_HAL\_Getchar10 ( UART0\_Type \* *base*, uint16\_t \* *readData* )**

Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>base</i>     | LPSCI module base pointer.                                |
| <i>readData</i> | The received data read from data register of size 10-bit. |

**38.2.3.21 void LPSCI\_HAL\_SendDataPolling ( UART0\_Type \* *base*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )**

This function only supports 8-bit transaction.

Parameters

|               |                                                     |
|---------------|-----------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                          |
| <i>txBuff</i> | The buffer pointer which saves the data to be sent. |
| <i>txSize</i> | Size of data to be sent in unit of byte.            |

**38.2.3.22 lpsci\_status\_t LPSCI\_HAL\_ReceiveDataPolling ( UART0\_Type \* *base*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* )**

This function only supports 8-bit transaction.

Parameters

|               |                                                         |
|---------------|---------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                              |
| <i>rxBuff</i> | The buffer pointer which saves the data to be received. |
| <i>rxSize</i> | Size of data need to be received in unit of byte.       |

Returns

Whether the transaction is success or receive overrun.

**38.2.3.23 bool LPSCI\_HAL\_GetStatusFlag ( UART0\_Type \* *base*, lpsci\_status\_flag\_t *statusFlag* )**

Parameters

---

## LPSCI HAL driver

|                   |                            |
|-------------------|----------------------------|
| <i>base</i>       | LPSCI module base pointer. |
| <i>statusFlag</i> | Status flag name.          |

Returns

The status flag states.

### 38.2.3.24 `lpsci_status_t LPSCI_HAL_ClearStatusFlag ( UART0_Type * base, lpsci_status_flag_t statusFlag )`

This function allows the user to clear an individual and specific LPSCI status flag. Refer to structure definition `lpsci_status_flag_t` for list of status bits.

Parameters

|                   |                                         |
|-------------------|-----------------------------------------|
| <i>base</i>       | LPSCI module base pointer.              |
| <i>statusFlag</i> | The desired LPSCI status flag to clear. |

Returns

An error code or `kStatus_LPSCI_Success`.

### 38.2.3.25 `static void LPSCI_HAL_SetWaitModeOperation ( UART0_Type * base, lpsci_operation_config_t mode ) [inline], [static]`

The function configures the LPSCI to either operate or cease to operate when wait mode is entered.

Parameters

|             |                                                                             |
|-------------|-----------------------------------------------------------------------------|
| <i>base</i> | LPSCI module base pointer.                                                  |
| <i>mode</i> | The LPSCI wait mode operation - operates or ceases to operate in wait mode. |

### 38.2.3.26 `static lpsci_operation_config_t LPSCI_HAL_GetWaitModeOperation ( UART0_Type * base ) [inline], [static]`

This function returns `kLpSciOperates` if the LPSCI has been configured to operate in wait mode. Else it returns `KLpSciStops` if the LPSCI has been configured to cease-to-operate in wait mode.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

The LPSCI WAIT mode operation configuration, returns either kLpsciOperates or KLpsciStops.

**38.2.3.27 static void LPSCI\_HAL\_SetLoopCmd ( UART0\_Type \* *base*, bool *enable* ) [inline], [static]**

This function enables or disables the LPSCI loopback operation.

Parameters

|               |                                                                                   |
|---------------|-----------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                        |
| <i>enable</i> | The LPSCI loopback mode configuration, either disabled (false) or enabled (true). |

**38.2.3.28 static void LPSCI\_HAL\_SetReceiverSource ( UART0\_Type \* *base*, lpsci\_receiver\_source\_t *source* ) [inline], [static]**

This function enables or disables the LPSCI single-wire operation. In some LPSCI bases it is required that the transmitter/receiver be disabled before calling this function. This may be applied to all LPSCIs to ensure safe operation.

Parameters

|               |                                                                                      |
|---------------|--------------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                           |
| <i>source</i> | The LPSCI single-wire mode configuration, either disabled (false) or enabled (true). |

**38.2.3.29 static void LPSCI\_HAL\_SetTransmitterDir ( UART0\_Type \* *base*, lpsci\_singlewire\_txdir\_t *direction* ) [inline], [static]**

This function configures the transmitter direction when the LPSCI is configured for single-wire operation.

Parameters

\_\_\_\_\_

## LPSCI HAL driver

|                  |                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>      | LPSCI module base pointer.                                                                                                                                                                         |
| <i>direction</i> | The LPSCI single-wire mode transmit direction configuration of type <code>lpsci_singlewire_txdir_t</code> (either <code>kLpsciSinglewireTxdirIn</code> or <code>kLpsciSinglewireTxdirOut</code> ). |

### 38.2.3.30 `lpsci_status_t LPSCI_HAL_PutReceiverInStandbyMode ( UART0_Type * base )`

This function, when called, places the LPSCI receiver into standby mode. In some LPSCI bases, there are conditions that must be met before placing the receive in standby mode. Before placing LPSCI in standby, determine if receiver is set to wake on idle, and if receiver is already in idle state. NOTE: RWU should only be set with `C1[WAKE] = 0` (wake up on idle) if the channel is currently not idle. This can be determined by the `S2[RAF]` flag. If set to wake up FROM an IDLE event and the channel is already idle, it is possible that the LPSCI discards data because data must be received (or a LIN break detect) after an IDLE is detected before IDLE is allowed to be reasserted.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

Error code or `kStatus_LPSCI_Success`.

### 38.2.3.31 `static void LPSCI_HAL_PutReceiverInNormalMode ( UART0_Type * base ) [inline], [static]`

This function, when called, places the LPSCI receiver into normal mode and out of standby mode.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

### 38.2.3.32 `static bool LPSCI_HAL_IsReceiverInStandby ( UART0_Type * base ) [inline], [static]`

This function determines the state of the LPSCI receiver. If it returns true, the LPSCI receiver is in standby mode. If it returns false, the LPSCI receiver is in normal mode.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

The LPSCI receiver is in normal mode (false) or standby mode (true).

**38.2.3.33 static void LPSCI\_HAL\_SetReceiverWakeupMethod ( UART0\_Type \* *base*, lpsci\_wakeup\_method\_t *method* ) [inline], [static]**

This function configures the wakeup method of the LPSCI receiver from standby mode. The options are idle-line wake or address-mark wake.

Parameters

|               |                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                                                               |
| <i>method</i> | The LPSCI receiver wakeup method options: kLpsciIdleLineWake - Idle-line wake or kLpsciAddrMarkWake - address-mark wake. |

**38.2.3.34 static lpsci\_wakeup\_method\_t LPSCI\_HAL\_GetReceiverWakeupMethod ( UART0\_Type \* *base* ) [inline], [static]**

This function returns how the LPSCI receiver is configured to wake from standby mode. The wake method options that can be returned are kLpsciIdleLineWake or kLpsciAddrMarkWake.

Parameters

|             |                            |
|-------------|----------------------------|
| <i>base</i> | LPSCI module base pointer. |
|-------------|----------------------------|

Returns

The LPSCI receiver wakeup from standby method, false: kLpsciIdleLineWake (idle-line wake) or true: kLpsciAddrMarkWake (address-mark wake).

**38.2.3.35 void LPSCI\_HAL\_ConfigIdleLineDetect ( UART0\_Type \* *base*, uint8\_t *idleLine*, uint8\_t *rxWakeldleDetect* )**

This function allows the user to configure the LPSCI idle-line detect operation. There are two separate operations for the user to configure, the idle line bit-count start and the receive wake up affect on IDLE status bit. The user passes in a structure of type lpsci\_idle\_line\_config\_t.

## LPSCI HAL driver

### Parameters

|                          |                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>              | LPSCI module base pointer.                                                                                                                                                                                                                        |
| <i>idleLine</i>          | Idle bit count start: 0 - after start bit (default), 1 - after stop bit                                                                                                                                                                           |
| <i>rxWakeIdle-Detect</i> | Receiver Wake Up Idle Detect. IDLE status bit operation during receive standby. Controls whether idle character that wakes up receiver will also set IDLE status bit. 0 - IDLE status bit doesn't get set (default), 1 - IDLE status bit gets set |

### 38.2.3.36 `static void LPSCI_HAL_SetBreakCharTransmitLength ( UART0_Type * base, lpsci_break_char_length_t length ) [inline], [static]`

This function allows the user to configure the LPSCI break character transmit length. See the typedef `lpsci_break_char_length_t` for setting options. In some LPSCI bases it is required that the transmitter be disabled before calling this function. This may be applied to all LPSCIs to ensure safe operation.

### Parameters

|               |                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                                                                                         |
| <i>length</i> | The LPSCI break character length setting of type <code>lpsci_break_char_length_t</code> , either a minimum 10-bit times or a minimum 13-bit times. |

### 38.2.3.37 `static void LPSCI_HAL_SetBreakCharDetectLength ( UART0_Type * base, lpsci_break_char_length_t length ) [inline], [static]`

This function allows the user to configure the LPSCI break character detect length. See the typedef `lpsci_break_char_length_t` for setting options.

### Parameters

|               |                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                                                                                         |
| <i>length</i> | The LPSCI break character length setting of type <code>lpsci_break_char_length_t</code> , either a minimum 10-bit times or a minimum 13-bit times. |

### 38.2.3.38 `static void LPSCI_HAL_SetBreakCharCmd ( UART0_Type * base, bool enable ) [inline], [static]`

This function allows the user to queue a LPSCI break character to send. If true is passed into the function, a break character is queued for transmission. A break character is continuously be queued until this function is called again when a false is passed into this function.

## Parameters

|               |                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPSCI module base pointer.                                                                                                                                                                |
| <i>enable</i> | If false, the LPSCI normal/queue break character setting is disabled, which configures the LPSCI for normal transmitter operation. If true, a break character is queued for transmission. |

**38.2.3.39 void LPSCI\_HAL\_SetMatchAddress ( UART0\_Type \* *base*, bool *matchAddrMode1*, bool *matchAddrMode2*, uint8\_t *matchAddrValue1*, uint8\_t *matchAddrValue2* )**

Note that this feature is available on select LPSCI bases.

The function allows the user to configure the LPSCI match address control operation. The user has the option to enable the match address mode and to program the match address value. There are two match address modes, each with its own enable and programmable match address value.

## Parameters

|                         |                                                                           |
|-------------------------|---------------------------------------------------------------------------|
| <i>base</i>             | LPSCI module base pointer.                                                |
| <i>matchAddr-Mode1</i>  | If true, this enables match address mode 1 (MAEN1), where false disables. |
| <i>matchAddr-Mode2</i>  | If true, this enables match address mode 2 (MAEN2), where false disables. |
| <i>matchAddr-Value1</i> | The match address value to program for match address mode 1.              |
| <i>matchAddr-Value2</i> | The match address value to program for match address mode 2.              |

## LPSCI Peripheral driver

### 38.3 LPSCI Peripheral driver

#### 38.3.1 Overview

The section describes the programming interface of the LPSCI Peripheral driver. The LPSCI peripheral driver transfers data to and from external devices on the Universal Asynchronous Receiver/Transmitter (LPSCI) serial bus with a single function call.

#### 38.3.2 LPSCI Device structures

The driver uses an instantiation of the `lpsci_state_t` structure to maintain the current state of a particular LPSCI instance module driver. This structure holds data used by the LPSCI Peripheral driver to communicate between the transmit and receive transfer functions and the interrupt handler. The interrupt handler also uses this information to keep track of its progress. Because the driver itself does not statically allocate memory, the caller provides memory for the driver state structure during initialization. The user is required to pass in the memory for the run-time state structure. The LPSCI driver populates the structure members.

#### 38.3.3 LPSCI User configuration structures

The LPSCI driver uses instances of the user configuration structure, `lpsci_user_config_t`, for the LPSCI driver. As a result, the most common settings of the LPSCI are configured with a single function call. Settings include: LPSCI baud rate; LPSCI parity mode: disabled (default), or even or odd; the number of stop bits; the number of bits per data word.

#### 38.3.4 LPSCI Initialization

1. To initialize the LPSCI driver, call the `LPSCI_DRV_Init()` function and pass the instance number of the relevant LPSCI peripheral, memory for the run-time state structure, and a pointer to the user configuration structure. For example, to use LPSCI0 pass a value of 0 to the initialization function.
2. Then, pass the memory for the run-time state structure and, finally, pass a user configuration structure of the type `lpsci_user_config_t` as shown here:

```
// LPSCI configuration structure
typedef struct LpSciUserConfig {
 uint32_t baudRate;
 lpsci_parity_mode_t parityMode;
 lpsci_stop_bit_count_t stopBitCount;
 lpsci_bit_count_per_char_t bitCountPerChar;
} lpsci_user_config_t;
```

Typically, the `lpsci_user_config_t` instantiation is configured as a 8-bit-character, no-parity, 1-stop-bit (8-n-1) with a 9600 bps baud rate. The `lpsci_user_config_t` instantiation can be easily modified to configure the LPSCI Peripheral driver either to a different baud rate or character transfer features. This is an example code to set up a user LPSCI configuration instantiation:

```
lpsci_user_config_t lpsciConfig;
lpsciConfig.baudRate = 9600;
lpsciConfig.bitCountPerChar = kLpSci8BitsPerChar;
lpsciConfig.parityMode = kLpSciParityDisabled;
lpsciConfig.stopBitCount = kLpSciOneStopBit;
```

This example shows how to call the `LPSCI_DRV_Init()` function given the user configuration structure and the LPSCI instance 0.

```
uint32_t lpsciInstance = 0;
lpsci_state_t lpsciState; // user provides memory for the driver state structure

LPSCI_DRV_Init(lpsciInstance, &lpsciConfig, &lpsciState);
```

### 38.3.5 LPSCI Transfers

The driver implements transmit and receive functions to transfer buffers of data. The driver also supports two different modes for transferring data: blocking and non-blocking.

The non-blocking transmit and receive functions include the `LPSCI_DRV_SendData()` and `LPSCI_DRV_ReceiveData()` functions.

The blocking (async) transmit and receive functions include the `LPSCI_DRV_SendDataBlocking()` and `LPSCI_DRV_ReceiveDataBlocking()` functions.

In all cases mentioned here, the functions are interrupt-driven.

These code examples show how to use previously mentioned functions and assume that the LPSCI module has been initialized as described previously in the Initialization Section.

For blocking transfer functions transmit and receive:

```
uint8_t sourceBuff[26] = {0}; // sourceBuff is populated with desired data
uint8_t readBuffer[10] = {0}; // readBuffer is populated with LPSCI_DRV_ReceiveData function

uint32_t byteCount = sizeof(sourceBuff);
uint32_t rxRemainingSize = sizeof(readBuffer);

// for each use there, set timeout as "1"
// lpsciState is the run-time state. Pass in memory for this
// declared previously in the initialization chapter
LPSCI_DRV_SendDataBlocking(&lpsciState, sourceBuff, byteCount, 1); // function
 won't return until transmit is complete
LPSCI_DRV_ReceiveDataBlocking(&lpsciState, readBuffer, 1, timeoutValue); //
 function won't return until it receives all data
```

For non-blocking (async) transfer functions transmit and receive:

```
uint8_t *pTxBuff;
uint8_t rxBuff[10];
uint32_t txBytesRemaining, rxBytesRemaining;

// assume pTxBuff and txSize have been initialized
LPSCI_DRV_SendData(&lpsciState, pTxBuff, txSize);

// now check on status of transmit and wait until done, the code can do something else and
```

## LPSCI Peripheral driver

```
// check back later, this is just an example
while (LPSCI_DRV_GetTransmitStatus(&lpsciState, &txBytesRemaining) ==
 kStatus_LPSCI_TxBusy);

// for receive, assume rxBuff is set up to receive data and rxSize is initialized
LPSCI_DRV_ReceiveData(&lpsciState, rxBuff, rxSize);

// now check on status of receive and wait until done, the code can do something else and
// check back later, this is just an example
while (LPSCI_DRV_GetReceiveStatus(&lpsciState, &rxBytesRemaining) ==
 kStatus_LPSCI_RxBusy);
```

## LPSCI Peripheral driver

### 38.3.7 Typedef Documentation

#### 38.3.7.1 typedef void(\* lpsci\_rx\_callback\_t)(uint32\_t instance, void \*lpsciState)

### 38.3.8 Function Documentation

#### 38.3.8.1 lpsci\_status\_t LPSCI\_DRV\_DmaInit ( uint32\_t instance, lpsci\_dma\_state\_t \* lpsciDmaStatePtr, const lpsci\_dma\_user\_config\_t \* lpsciUserConfig )

This function initializes the run-time state structure to keep track of the on-going transfers, un-gates the clock to the LPSCI module, initializes the module to user-defined settings and default settings, configures the IRQ state structure, and enables the module-level interrupt to the core, the LPSCI module transmitter and receiver. This example shows how to set up the `lpsci_dma_state_t` and the `lpsci_user_config_t` parameters and how to call the `LPSCI_DRV_DmaInit` function by passing in these parameters:

```
lpsci_user_config_t lpsciConfig;
lpsciConfig.baudRate = 9600;
lpsciConfig.bitCountPerChar = kLpsci8BitsPerChar;
lpsciConfig.parityMode = kLpsciParityDisabled;
lpsciConfig.stopBitCount = kLpsciOneStopBit;
lpsci_dma_state_t lpsciDmaState;
LPSCI_DRV_DmaInit(instance, &lpsciDmaState, &lpsciConfig);
```

#### Parameters

|                          |                                                                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>          | The LPSCI instance number.                                                                                                                                                                                                                   |
| <i>lpsciDmaState-Ptr</i> | A pointer to the LPSCI driver state structure memory. The user passes in the memory for the run-time state structure. The LPSCI driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>lpsciUser-Config</i>  | The user configuration structure of type <code>lpsci_user_config_t</code> . The user populates the members of this structure and passes the pointer of this structure to this function.                                                      |

#### Returns

An error code or `kStatus_LPSCI_Success`.

#### 38.3.8.2 lpsci\_status\_t LPSCI\_DRV\_DmaDeinit ( uint32\_t instance )

This function disables the LPSCI-DMA trigger and disables the transmitter and receiver.

Parameters

|                 |                            |
|-----------------|----------------------------|
| <i>instance</i> | The LPSCI instance number. |
|-----------------|----------------------------|

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.3** `lpsci_status_t LPSCI_DRV_DmaSendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout )`

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPSCI instance number.                                              |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>   | The number of bytes to send.                                            |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.4** `lpsci_status_t LPSCI_DRV_DmaSendData ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize )`

Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                      |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.5** `lpsci_status_t LPSCI_DRV_DmaGetTransmitStatus ( uint32_t instance, uint32_t * bytesRemaining )`

## LPSCI Peripheral driver

### Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPSCI module base address.                                                                             |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

### Returns

An error code or `kStatus_LPSCI_Success`.

### Return values

|                              |                                                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPSCI_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_LPSCI_TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

### 38.3.8.6 `lpsci_status_t LPSCI_DRV_DmaAbortSendingData ( uint32_t instance )`

#### Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>instance</i> | The LPSCI module base address. |
|-----------------|--------------------------------|

#### Returns

An error code or `kStatus_LPSCI_Success`.

#### Return values

|                                            |                                           |
|--------------------------------------------|-------------------------------------------|
| <i>kStatus_LPSCI_Success</i>               | The transmit was successful.              |
| <i>kStatus_LPSCI_No-TransmitInProgress</i> | No transmission is currently in progress. |

### 38.3.8.7 `lpsci_status_t LPSCI_DRV_DmaReceiveDataBlocking ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout )`

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                          |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.8 lpsci\_status\_t LPSCI\_DRV\_DmaReceiveData ( uint32\_t *instance*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* )**

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                     |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>   | The number of bytes to receive.                                    |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.9 lpsci\_status\_t LPSCI\_DRV\_DmaGetReceiveStatus ( uint32\_t *instance*, uint32\_t \* *bytesRemaining* )**

Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPSCI module base address.                                                                                          |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes which still need to be received in the active transfer. |

## LPSCI Peripheral driver

Returns

An error code or `kStatus_LPSCI_Success`.

Return values

|                                    |                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>kStatus_LPSCI_Success</code> | The receive has completed successfully.                                                                                        |
| <code>kStatus_LPSCI_RxBusy</code>  | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

### 38.3.8.10 `lpsci_status_t LPSCI_DRV_DmaAbortReceivingData ( uint32_t instance )`

Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>instance</i> | The LPSCI module base address. |
|-----------------|--------------------------------|

Returns

An error code or `kStatus_LPSCI_Success`.

Return values

|                                                  |                                      |
|--------------------------------------------------|--------------------------------------|
| <code>kStatus_LPSCI_Success</code>               | The receive was successful.          |
| <code>kStatus_LPSCI_No-TransmitInProgress</code> | No receive is currently in progress. |

### 38.3.8.11 `lpsci_status_t LPSCI_DRV_Init ( uint32_t instance, lpsci_state_t * lpsciStatePtr, const lpsci_user_config_t * lpsciUserConfig )`

This function initializes the run-time state structure to keep track of the on-going transfers, un-gates the clock to the LPSCI module, initializes the module to user-defined settings and default settings, configures the IRQ state structure and enables the module-level interrupt to the core, and enables the LPSCI module transmitter and receiver. This example shows how to set up the `lpsci_state_t` and the `lpsci_user_config_t` parameters and how to call the `LPSCI_DRV_Init` function by passing in these parameters:

```
lpsci_user_config_t lpsciConfig;
lpsciConfig.clockSource = kClockLpSrcPllFllSel;
lpsciConfig.baudRate = 9600;
lpsciConfig.bitCountPerChar = kLpSci8BitsPerChar;
lpsciConfig.parityMode = kLpSciParityDisabled;
lpsciConfig.stopBitCount = kLpSciOneStopBit;
lpsci_state_t lpsciState;
LPSCI_DRV_Init(instance, &lpsciState, &lpsciConfig);
```

Parameters

|                         |                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>         | The LPSCI instance number.                                                                                                                                                                                                                  |
| <i>lpsciStatePtr</i>    | A pointer to the LPSCI driver state structure memory. The user passes in the memory for the run-time state structure. The LPSCI driver populates the members. The run-time state structure keeps track of the current transfer in progress. |
| <i>lpsciUser-Config</i> | The user configuration structure of type <a href="#">lpsci_user_config_t</a> . The user populates the members of this structure and passes the pointer of the structure to the function.                                                    |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.12 lpsci\_status\_t LPSCI\_DRV\_Deinit ( uint32\_t instance )**

This function disables the LPSCI interrupts, disables the transmitter and receiver, and flushes the FIFOs (for modules that support FIFOs).

Parameters

|                 |                            |
|-----------------|----------------------------|
| <i>instance</i> | The LPSCI instance number. |
|-----------------|----------------------------|

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.13 lpsci\_rx\_callback\_t LPSCI\_DRV\_InstallRxCallback ( uint32\_t instance, lpsci\_rx\_callback\_t function, uint8\_t \* rxBuff, void \* callbackParam, bool alwaysEnableRxIrq )**

Parameters

|                 |                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------|
| <i>instance</i> | The LPSCI instance number.                                                                                 |
| <i>function</i> | The LPSCI receive callback function.                                                                       |
| <i>rxBuff</i>   | The receive buffer used inside IRQHandler. This buffer must be kept as long as the callback is functional. |

## LPSCI Peripheral driver

|                           |                                               |
|---------------------------|-----------------------------------------------|
| <i>callbackParam</i>      | The LPSCI receive callback parameter pointer. |
| <i>alwaysEnable-RxIrq</i> | Whether always enable receive IRQ or not.     |

### Returns

Former LPSCI receive callback function pointer.

#### 38.3.8.14 `lpsci_tx_callback_t LPSCI_DRV_InstallTxCallback ( uint32_t instance, lpsci_tx_callback_t function, uint8_t * txBuff, void * callbackParam )`

### Note

After the callback is installed, it bypasses part of the LPSCI IRQHandler logic. Therefore, the callback needs to handle the indexes of txBuff and txSize.

### Parameters

|                      |                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------|
| <i>instance</i>      | The LPSCI instance number.                                                                             |
| <i>function</i>      | The LPSCI transmit callback function.                                                                  |
| <i>txBuff</i>        | The transmit buffer used inside IRQHandler. This buffer must be kept as long as the callback is alive. |
| <i>callbackParam</i> | The LPSCI transmit callback parameter pointer.                                                         |

### Returns

Former LPSCI transmit callback function pointer.

#### 38.3.8.15 `lpsci_status_t LPSCI_DRV_SendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout )`

A blocking (also known as synchronous) function means that the function does not return until the transmit is complete. This blocking function sends data through the LPSCI port.

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPSCI instance number.                                              |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>   | The number of bytes to send.                                            |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.16 lpsci\_status\_t LPSCI\_DRV\_SendData ( uint32\_t instance, const uint8\_t \* txBuff, uint32\_t txSize )**

A non-blocking (also known as synchronous) function means that the function returns immediately after initiating the transmit function. The application has to get the transmit status to see when the transmit is complete. In other words, after calling non-blocking (asynchronous) send function, the application must get the transmit status to check if transmit is complete. The asynchronous method of transmitting and receiving allows the LPSCI to perform a full duplex operation (simultaneously transmit and receive).

Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                      |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.17 lpsci\_status\_t LPSCI\_DRV\_GetTransmitStatus ( uint32\_t instance, uint32\_t \* bytesRemaining )**

When performing an a-sync transmit, call this function to ascertain the state of the current transmission: in progress (or busy) or complete (success). If the transmission is still in progress, the user can obtain the number of words that have been transferred.

Parameters

---

## LPSCI Peripheral driver

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPSCI module base address.                                                                             |
| <i>bytes-Remaining</i> | A pointer to a value that is filled in with the number of bytes that are remaining in the active transfer. |

Returns

Current transmission status.

Return values

|                              |                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPSCI_Success</i> | The transmit has completed successfully.                                                                                            |
| <i>kStatus_LPSCI_TxBusy</i>  | The transmit is still in progress. <i>bytesRemaining</i> is filled with the number of bytes which are transmitted up to that point. |

### 38.3.8.18 `lpsci_status_t LPSCI_DRV_AbortSendingData ( uint32_t instance )`

During an a-sync LPSCI transmission, the user can terminate the transmission early if the transmission is still in progress.

Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>instance</i> | The LPSCI module base address. |
|-----------------|--------------------------------|

Returns

Whether the aborting was successful or not.

Return values

|                                            |                                           |
|--------------------------------------------|-------------------------------------------|
| <i>kStatus_LPSCI_Success</i>               | The transmit was successful.              |
| <i>kStatus_LPSCI_No-TransmitInProgress</i> | No transmission is currently in progress. |

### 38.3.8.19 `lpsci_status_t LPSCI_DRV_ReceiveDataBlocking ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout )`

A blocking (also known as synchronous) function does not return until the receive is complete. This blocking function sends data through the LPSCI port.

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                          |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.20 lpsci\_status\_t LPSCI\_DRV\_ReceiveData ( uint32\_t *instance*, uint8\_t \* *rxBuff*, uint32\_t *rxSize* )**

A non-blocking (also known as synchronous) function returns immediately after initiating the receive function. The application has to get the receive status to see when the receive is complete. The asynchronous method of transmitting and receiving allows the LPSCI to perform a full duplex operation (simultaneously transmit and receive).

Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPSCI module base address.                                     |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>   | The number of bytes to receive.                                    |

Returns

An error code or kStatus\_LPSCI\_Success.

**38.3.8.21 lpsci\_status\_t LPSCI\_DRV\_GetReceiveStatus ( uint32\_t *instance*, uint32\_t \* *bytesRemaining* )**

When performing an a-sync receive, call this function to ascertain the state of the current receive progress: in progress (or busy) or complete (success). If the receive is still in progress, the user can obtain the number of words that have been received.

## LPSCI Peripheral driver

### Parameters

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPSCI module base address.                                                                                          |
| <i>bytes-Remaining</i> | A pointer to a value that is filled in with the number of bytes which still need to be received in the active transfer. |

### Returns

Current receive status.

### Return values

|                              |                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPSCI_Success</i> | The receive has completed successfully.                                                                                         |
| <i>kStatus_LPSCI_RxBusy</i>  | The receive is still in progress. <i>bytesRemaining</i> is filled with the number of bytes which are received up to that point. |

### 38.3.8.22 `lpsci_status_t LPSCI_DRV_AbortReceivingData ( uint32_t instance )`

During an a-sync LPSCI receive, the user can terminate the receive early if the receive is still in progress.

### Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>instance</i> | The LPSCI module base address. |
|-----------------|--------------------------------|

### Returns

Whether the action success or not.

### Return values

|                                            |                                      |
|--------------------------------------------|--------------------------------------|
| <i>kStatus_LPSCI_Success</i>               | The receive was successful.          |
| <i>kStatus_LPSCI_No-TransmitInProgress</i> | No receive is currently in progress. |

## 38.3.9 Variable Documentation

**38.3.9.1** `UART0_Type* const g_lpsciBase[UART0_INSTANCE_COUNT]`

**38.3.9.2** `UART0_Type* const g_lpsciBase[UART0_INSTANCE_COUNT]`

## Chapter 39

### Low Power Timer (LPTMR)

#### 39.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Low Power Timer (LPTMR) block of Kinetis devices.

#### Modules

- [LPTMR HAL driver](#)
- [LPTMR Peripheral driver](#)

## LPTMR HAL driver

### 39.2 LPTMR HAL driver

#### 39.2.1 Overview

This section describes the programming interface of the LPTMR HAL driver.

#### Data Structures

- struct [lptmr\\_prescaler\\_user\\_config\\_t](#)  
*Define LPTMR prescaler user configure. [More...](#)*
- struct [lptmr\\_working\\_mode\\_user\\_config\\_t](#)  
*Define LPTMR working mode user configure. [More...](#)*

#### Enumerations

- enum [lptmr\\_pin\\_select\\_t](#) {  
[kLptmrPinSelectInput0](#) = 0x0U,  
[kLptmrPinSelectInput1](#) = 0x1U,  
[kLptmrPinSelectInput2](#) = 0x2U,  
[kLptmrPinSelectInput3](#) = 0x3U }  
*LPTMR pin selection, used in pulse counter mode.*
- enum [lptmr\\_pin\\_polarity\\_t](#) {  
[kLptmrPinPolarityActiveHigh](#) = 0x0U,  
[kLptmrPinPolarityActiveLow](#) = 0x1U }  
*LPTMR pin polarity, used in pulse counter mode.*
- enum [lptmr\\_timer\\_mode\\_t](#) {  
[kLptmrTimerModeTimeCounter](#) = 0x0U,  
[kLptmrTimerModePulseCounter](#) = 0x1U }  
*LPTMR timer mode selection.*
- enum [lptmr\\_prescaler\\_value\\_t](#) {  
[kLptmrPrescalerDivide2](#) = 0x0U,  
[kLptmrPrescalerDivide4GlitchFilter2](#) = 0x1U,  
[kLptmrPrescalerDivide8GlitchFilter4](#) = 0x2U,  
[kLptmrPrescalerDivide16GlitchFilter8](#) = 0x3U,  
[kLptmrPrescalerDivide32GlitchFilter16](#) = 0x4U,  
[kLptmrPrescalerDivide64GlitchFilter32](#) = 0x5U,  
[kLptmrPrescalerDivide128GlitchFilter64](#) = 0x6U,  
[kLptmrPrescalerDivide256GlitchFilter128](#) = 0x7U,  
[kLptmrPrescalerDivide512GlitchFilter256](#) = 0x8U,  
[kLptmrPrescalerDivide1024GlitchFilter512](#) = 0x9U,  
[kLptmrPrescalerDivide2048GlitchFilter1024](#) = 0xAU,  
[kLptmrPrescalerDivide4096GlitchFilter2048](#) = 0xBU,  
[kLptmrPrescalerDivide8192GlitchFilter4096](#) = 0xCU,  
[kLptmrPrescalerDivide16384GlitchFilter8192](#) = 0xDU,  
[kLptmrPrescalerDivide32768GlitchFilter16384](#) = 0xEU,

- `kLptmrPrescalerDivide65536GlitchFilter32768 = 0xFU }`
- LPTMR prescaler value.*
- enum `lptmr_prescaler_clock_select_t` {
  - `kLptmrPrescalerClock0 = 0x0U,`
  - `kLptmrPrescalerClock1 = 0x1U,`
  - `kLptmrPrescalerClock2 = 0x2U,`
  - `kLptmrPrescalerClock3 = 0x3U }`
- LPTMR prescaler/glitch filter clock select.*
- enum `lptmr_status_t` {
  - `kStatus_LPTMR_Success = 0x0U,`
  - `kStatus_LPTMR_NotInitialized = 0x1U,`
  - `kStatus_LPTMR_NullArgument = 0x2U,`
  - `kStatus_LPTMR_InvalidPrescalerValue = 0x3U,`
  - `kStatus_LPTMR_InvalidInTimeCounterMode = 0x4U,`
  - `kStatus_LPTMR_InvalidInPulseCounterMode = 0x5U,`
  - `kStatus_LPTMR_TcfNotSet = 0x6U,`
  - `kStatus_LPTMR_TimerPeriodUsTooSmall = 0x7U,`
  - `kStatus_LPTMR_TimerPeriodUsTooLarge = 0x8U }`
- LPTMR status return codes.*

## LPTMR HAL.

- static void `LPTMR_HAL_Enable` (`LPTMR_Type *base`)
  - Enables the LPTMR module operation.*
- static void `LPTMR_HAL_Disable` (`LPTMR_Type *base`)
  - Disables the LPTMR module operation.*
- static void `LPTMR_HAL_ClearIntFlag` (`LPTMR_Type *base`)
  - Clears the LPTMR interrupt flag if set.*
- static bool `LPTMR_HAL_IsIntPending` (`LPTMR_Type *base`)
  - Returns the current LPTMR interrupt flag.*
- static void `LPTMR_HAL_SetIntCmd` (`LPTMR_Type *base`, bool enable)
  - Enables or disables the LPTMR interrupt.*
- void `LPTMR_HAL_SetTimerWorkingMode` (`LPTMR_Type *base`, `lptmr_working_mode_user_config_t` timerMode)
  - Configures the LPTMR working mode.*
- void `LPTMR_HAL_SetPrescalerMode` (`LPTMR_Type *base`, `lptmr_prescaler_user_config_t` prescaler\_config)
  - Sets the LPTMR prescaler mode.*
- static void `LPTMR_HAL_SetCompareValue` (`LPTMR_Type *base`, `uint32_t` compareValue)
  - Sets the LPTMR compare value.*
- static `uint32_t` `LPTMR_HAL_GetCompareValue` (`LPTMR_Type *base`)
  - Gets the LPTMR compare value.*
- `uint32_t` `LPTMR_HAL_GetCounterValue` (`LPTMR_Type *base`)
  - Gets the LPTMR counter value.*
- void `LPTMR_HAL_Init` (`LPTMR_Type *base`)
  - Restores the LPTMR module to reset state.*

## LPTMR HAL driver

### 39.2.2 Data Structure Documentation

#### 39.2.2.1 struct `lptmr_prescaler_user_config_t`

##### Data Fields

- bool `prescalerBypass`  
*Set this value will by pass the prescaler or glitch filter.*
- `lptmr_prescaler_clock_select_t` `prescalerClockSelect`  
*Selects the clock to be used by the LPTMR prescaler/glitch filter.*
- `lptmr_prescaler_value_t` `prescalerValue`  
*Configures the size of the prescaler in time counter mode or width of the glitch filter in pulse counter mode.*

#### 39.2.2.1.0.142 Field Documentation

##### 39.2.2.1.0.142.1 bool `lptmr_prescaler_user_config_t::prescalerBypass`

##### 39.2.2.1.0.142.2 `lptmr_prescaler_clock_select_t` `lptmr_prescaler_user_config_t::prescalerClockSelect`

##### 39.2.2.1.0.142.3 `lptmr_prescaler_value_t` `lptmr_prescaler_user_config_t::prescalerValue`

#### 39.2.2.2 struct `lptmr_working_mode_user_config_t`

##### Data Fields

- `lptmr_timer_mode_t` `timerModeSelect`  
*Selects the LPTMR working mode: Timer or Pulse Counter.*
- bool `freeRunningEnable`  
*Enables or disables the LPTMR free running.*
- `lptmr_pin_polarity_t` `pinPolarity`  
*Specifies LPTMR pulse input pin polarity.*
- `lptmr_pin_select_t` `pinSelect`  
*Specifies LPTMR pulse input pin select.*

### 39.2.2.2.0.143 Field Documentation

39.2.2.2.0.143.1 `lptmr_timer_mode_t` `lptmr_working_mode_user_config_t::timerModeSelect`

39.2.2.2.0.143.2 `bool` `lptmr_working_mode_user_config_t::freeRunningEnable`

39.2.2.2.0.143.3 `lptmr_pin_polarity_t` `lptmr_working_mode_user_config_t::pinPolarity`

39.2.2.2.0.143.4 `lptmr_pin_select_t` `lptmr_working_mode_user_config_t::pinSelect`

## 39.2.3 Enumeration Type Documentation

### 39.2.3.1 enum `lptmr_pin_select_t`

Enumerator

***`kLptmrPinSelectInput0`*** Pulse counter input 0 is selected.  
***`kLptmrPinSelectInput1`*** Pulse counter input 1 is selected.  
***`kLptmrPinSelectInput2`*** Pulse counter input 2 is selected.  
***`kLptmrPinSelectInput3`*** Pulse counter input 3 is selected.

### 39.2.3.2 enum `lptmr_pin_polarity_t`

Enumerator

***`kLptmrPinPolarityActiveHigh`*** Pulse Counter input source is active-high.  
***`kLptmrPinPolarityActiveLow`*** Pulse Counter input source is active-low.

### 39.2.3.3 enum `lptmr_timer_mode_t`

Enumerator

***`kLptmrTimerModeTimeCounter`*** Time Counter mode.  
***`kLptmrTimerModePulseCounter`*** Pulse Counter mode.

### 39.2.3.4 enum `lptmr_prescaler_value_t`

Enumerator

***`kLptmrPrescalerDivide2`*** Prescaler divide 2, glitch filter invalid.  
***`kLptmrPrescalerDivide4GlitchFilter2`*** Prescaler divide 4, glitch filter 2.  
***`kLptmrPrescalerDivide8GlitchFilter4`*** Prescaler divide 8, glitch filter 4.  
***`kLptmrPrescalerDivide16GlitchFilter8`*** Prescaler divide 16, glitch filter 8.  
***`kLptmrPrescalerDivide32GlitchFilter16`*** Prescaler divide 32, glitch filter 16.

## LPTMR HAL driver

*kLptmrPrescalerDivide64GlitchFilter32* Prescaler divide 64, glitch filter 32.  
*kLptmrPrescalerDivide128GlitchFilter64* Prescaler divide 128, glitch filter 64.  
*kLptmrPrescalerDivide256GlitchFilter128* Prescaler divide 256, glitch filter 128.  
*kLptmrPrescalerDivide512GlitchFilter256* Prescaler divide 512, glitch filter 256.  
*kLptmrPrescalerDivide1024GlitchFilter512* Prescaler divide 1024, glitch filter 512.  
*kLptmrPrescalerDivide2048GlitchFilter1024* Prescaler divide 2048 glitch filter 1024.  
*kLptmrPrescalerDivide4096GlitchFilter2048* Prescaler divide 4096, glitch filter 2048.  
*kLptmrPrescalerDivide8192GlitchFilter4096* Prescaler divide 8192, glitch filter 4096.  
*kLptmrPrescalerDivide16384GlitchFilter8192* Prescaler divide 16384, glitch filter 8192.  
*kLptmrPrescalerDivide32768GlitchFilter16384* Prescaler divide 32768, glitch filter 16384.  
*kLptmrPrescalerDivide65536GlitchFilter32768* Prescaler divide 65536, glitch filter 32768.

### 39.2.3.5 enum lptmr\_prescaler\_clock\_select\_t

Enumerator

*kLptmrPrescalerClock0* Prescaler/glitch filter clock 0 selected.  
*kLptmrPrescalerClock1* Prescaler/glitch filter clock 1 selected.  
*kLptmrPrescalerClock2* Prescaler/glitch filter clock 2 selected.  
*kLptmrPrescalerClock3* Prescaler/glitch filter clock 3 selected.

### 39.2.3.6 enum lptmr\_status\_t

Enumerator

*kStatus\_LPTMR\_Success* Succeed.  
*kStatus\_LPTMR\_NotInitialized* LPTMR is not initialized yet.  
*kStatus\_LPTMR\_NullArgument* Argument is NULL.  
*kStatus\_LPTMR\_InvalidPrescalerValue* Value 0 is not valid in pulse counter mode.  
*kStatus\_LPTMR\_InvalidInTimeCounterMode* Function cannot be called in time counter mode.  
*kStatus\_LPTMR\_InvalidInPulseCounterMode* Function cannot be called in pulse counter mode.  
*kStatus\_LPTMR\_TcfNotSet* If LPTMR is enabled, compare register can only altered when TCF is set.  
*kStatus\_LPTMR\_TimerPeriodUsTooSmall* Timer period time is too small for current clock source.  
*kStatus\_LPTMR\_TimerPeriodUsTooLarge* Timer period time is too large for current clock source.

## 39.2.4 Function Documentation

39.2.4.1 `static void LPTMR_HAL_Enable ( LPTMR_Type * base ) [inline], [static]`

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPTMR peripheral base address. |
|-------------|------------------------------------|

**39.2.4.2 static void LPTMR\_HAL\_Disable ( LPTMR\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPTMR peripheral base address. |
|-------------|------------------------------------|

**39.2.4.3 static void LPTMR\_HAL\_ClearIntFlag ( LPTMR\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPTMR peripheral base address. |
|-------------|------------------------------------|

**39.2.4.4 static bool LPTMR\_HAL\_IsIntPending ( LPTMR\_Type \* *base* ) [inline], [static]**

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPTMR peripheral base address |
|-------------|-----------------------------------|

Returns

State of LPTMR interrupt flag

Return values

|              |                          |
|--------------|--------------------------|
| <i>true</i>  | An interrupt is pending. |
| <i>false</i> | No interrupt is pending. |

**39.2.4.5 static void LPTMR\_HAL\_SetIntCmd ( LPTMR\_Type \* *base*, bool *enable* ) [inline], [static]**

## LPTMR HAL driver

Parameters

|               |                                     |
|---------------|-------------------------------------|
| <i>base</i>   | The LPTMR peripheral base address   |
| <i>enable</i> | Pass true to enable LPTMR interrupt |

**39.2.4.6 void LPTMR\_HAL\_SetTimerWorkingMode ( LPTMR\_Type \* *base*,  
lptmr\_working\_mode\_user\_config\_t *timerMode* )**

Parameters

|                  |                                                                                              |
|------------------|----------------------------------------------------------------------------------------------|
| <i>base</i>      | The LPTMR peripheral base address.                                                           |
| <i>timerMode</i> | Specifies LPTMR working mode configure, see <a href="#">lptmr_working_mode_user_config_t</a> |

**39.2.4.7 void LPTMR\_HAL\_SetPrescalerMode ( LPTMR\_Type \* *base*,  
lptmr\_prescaler\_user\_config\_t *prescaler\_config* )**

Parameters

|                                    |                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------|
| <i>base</i>                        | The LPTMR peripheral base address.                                                     |
| <i>prescaler_</i><br><i>config</i> | Specifies LPTMR prescaler configure, see <a href="#">lptmr_prescaler_user_config_t</a> |

**39.2.4.8 static void LPTMR\_HAL\_SetCompareValue ( LPTMR\_Type \* *base*, uint32\_t  
*compareValue* ) [inline], [static]**

Parameters

|                     |                                                  |
|---------------------|--------------------------------------------------|
| <i>base</i>         | The LPTMR peripheral base address.               |
| <i>compareValue</i> | Specifies LPTMR compare value, less than 0xFFFFU |

**39.2.4.9 static uint32\_t LPTMR\_HAL\_GetCompareValue ( LPTMR\_Type \* *base* )  
[inline], [static]**

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPTMR peripheral base address. |
|-------------|------------------------------------|

Returns

The LPTMR compare value.

**39.2.4.10 uint32\_t LPTMR\_HAL\_GetCounterValue ( LPTMR\_Type \* *base* )**

Parameters

|             |                                    |
|-------------|------------------------------------|
| <i>base</i> | The LPTMR peripheral base address. |
|-------------|------------------------------------|

Returns

Current LPTMR counter value

**39.2.4.11 void LPTMR\_HAL\_Init ( LPTMR\_Type \* *base* )**

Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>base</i> | The LPTMR peripheral base address |
|-------------|-----------------------------------|

## LPTMR Peripheral driver

### 39.3 LPTMR Peripheral driver

#### 39.3.1 Overview

This section describes the programming interface of the LPTMR Peripheral driver. The LPTMR driver configures the LPTMR.

#### 39.3.2 LPTMR Initialization

1. To initialize the LPTMR module, call the `LPTMR_DRV_Init()` function and pass in the user configuration data structure. This function automatically enables the LPTMR module and clock.
2. After the `LPTMR_DRV_Init()` function is called, call the `LPTMR_DRV_Start` to start the LPTMR.
3. To stop the LPTMR counter, call the `LPTMR_DRV_Stop`.

This is example code to configure the driver:

```
// Defines the LPTMR user configuration structure . //
const lptmr_user_config_t config =
{
 .timerMode = kLptmrTimerModeTimerCounter, // timer counter is selected//
 .freeRunningEnable = false, // free running is disabled //
 .intEnable = true, // interrupt is enabled //
 .compareValue = 1024, // compare value is 1024 //
 .prescalerEnable = true, // prescaler is enabled //
 .prescalerClockSource = kLptmrPrescalerClockSourceLpo, // prescaler clock is LPO //
 .prescalerValue = kLptmrPrescalerDivede2, // prelscaler divide is 2 //
};

// Initializes the LPTMR 0. //
LPTMR_DRV_Init(0,&config);

// Starts the LPTMR 0. //
LPTMR_DRV_Start(0);

// Stops LPTMR 0. //
LPTMR_DRV_Stop(0);

// Deinitializes LPTMR 0. //
LPTMR_DRV_Deinit(0);
```

#### 39.3.3 LPTMR Interrupt

1. Enable the LPTMR interrupt. The LPTMR interrupt is enabled in the user configuration structure with the `lptmr_user_config_t.intEnable=true`.
2. Define the LPTMR IRQ function.

```
void LPTimer_IRQHandler()
{
 if(true == LPTMR_DRV_IsIntPending(0))
 {
 LPTMR_DRV_ClearIntFlag(0);
 }
 lptmrIsrAssertCount++;
}
```

## Data Structures

- struct [lptmr\\_user\\_config\\_t](#)  
*Data structure to initialize the LPTMR. [More...](#)*
- struct [lptmr\\_state\\_t](#)  
*Internal driver state information. [More...](#)*

## Typedefs

- typedef void(\* [lptmr\\_callback\\_t](#))(void)  
*Defines a type of the user-defined callback function.*

## Variables

*Deinitializes the LPTMR driver.*
- [lptmr\\_status\\_t](#) [LPTMR\\_DRV\\_Start](#) (uint32\_t instance)  
*Starts the LPTMR counter.*
- [lptmr\\_status\\_t](#) [LPTMR\\_DRV\\_Stop](#) (uint32\_t instance)  
*Stops the LPTMR counter.*
- [lptmr\\_status\\_t](#) [LPTMR\\_DRV\\_SetTimerPeriodUs](#) (uint32\_t instance, uint32\_t us)  
*Configures the LPTMR timer period in microseconds.*
- uint32\_t [LPTMR\\_DRV\\_GetCurrentTimeUs](#) (uint32\_t instance)  
*Gets the current LPTMR time in microseconds.*
- [lptmr\\_status\\_t](#) [LPTMR\\_DRV\\_SetPulsePeriodCount](#) (uint32\_t instance, uint32\_t pulsePeriodCount)  
*Sets the pulse period value.*
- uint32\_t [LPTMR\\_DRV\\_GetCurrentPulseCount](#) (uint32\_t instance)  
*Gets the current pulse count.*
- [lptmr\\_status\\_t](#) [LPTMR\\_DRV\\_InstallCallback](#) (uint32\_t instance, [lptmr\\_callback\\_t](#) userCallback)  
*Installs the user-defined callback in the LPTMR module.*
- void [LPTMR\\_DRV\\_IRQHandler](#) (uint32\_t instance)  
*Driver-defined ISR in the LPTMR module.*

## LPTMR Peripheral driver

### 39.3.4 Data Structure Documentation

#### 39.3.4.1 struct lptmr\_user\_config\_t

This structure is used when initializing the LPTMR during the LPTMR\_DRV\_Init function call.

##### Data Fields

- [lptmr\\_timer\\_mode\\_t timerMode](#)  
*Timer counter mode or pulse counter mode.*
- [lptmr\\_pin\\_select\\_t pinSelect](#)  
*LPTMR pulse input pin select.*
- [lptmr\\_pin\\_polarity\\_t pinPolarity](#)  
*LPTMR pulse input pin polarity.*
- bool [freeRunningEnable](#)  
*Free running configure.*
- bool [prescalerEnable](#)  
*Prescaler enable configure.*
- [clock\\_lptmr\\_src\\_t prescalerClockSource](#)  
*LPTMR clock source.*
- [lptmr\\_prescaler\\_value\\_t prescalerValue](#)  
*Prescaler value.*
- bool [isInterruptEnabled](#)  
*Timer interrupt 0-disable/1-enable.*

##### 39.3.4.1.0.144 Field Documentation

###### 39.3.4.1.0.144.1 bool lptmr\_user\_config\_t::freeRunningEnable

True means enable free running

###### 39.3.4.1.0.144.2 bool lptmr\_user\_config\_t::prescalerEnable

True means enable prescaler

#### 39.3.4.2 struct lptmr\_state\_t

The contents of this structure are internal to the driver and should not be modified by users. Contents of the structure are subject to change in future releases.

##### Data Fields

- [lptmr\\_callback\\_t userCallbackFunc](#)  
*Callback function that is executed in ISR.*

### 39.3.4.2.0.145 Field Documentation

#### 39.3.4.2.0.145.1 `lptmr_callback_t lptmr_state_t::userCallbackFunc`

### 39.3.5 Function Documentation

#### 39.3.5.1 `lptmr_status_t LPTMR_DRV_Init ( uint32_t instance, lptmr_state_t * userStatePtr, const lptmr_user_config_t * userConfigPtr )`

This function initializes the LPTMR. The LPTMR can be initialized as a time counter or pulse counter, which is determined by the `timerMode` in the `lptmr_user_config_t`. `pinSelect` and `pinPolarity` do not need to be configured while working as a time counter.

Parameters

|                      |                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------|
| <i>instance</i>      | The LPTMR peripheral instance number.                                                        |
| <i>userStatePtr</i>  | The pointer to the structure of the context memory, see <a href="#">lptmr_state_t</a> .      |
| <i>userConfigPtr</i> | The pointer to the LPTMR user configure structure, see <a href="#">lptmr_user_config_t</a> . |

Returns

`kStatus_LPTMR_Success` means succeed, otherwise means failed.

#### 39.3.5.2 `lptmr_status_t LPTMR_DRV_Deinit ( uint32_t instance )`

This function deinitializes the LPTMR. It disables the interrupt and turns off the LPTMR clock.

Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
|-----------------|---------------------------------------|

Returns

`kStatus_LPTMR_Success` means succeed, otherwise means failed.

#### 39.3.5.3 `lptmr_status_t LPTMR_DRV_Start ( uint32_t instance )`

This function starts the LPTMR counter. Ensure that all necessary configurations are set before calling this function.

## LPTMR Peripheral driver

### Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
|-----------------|---------------------------------------|

### Returns

kStatus\_LPTMR\_Success means success. Otherwise, means failure.

#### 39.3.5.4 `lptmr_status_t LPTMR_DRV_Stop ( uint32_t instance )`

This function stops the LPTMR counter.

### Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
|-----------------|---------------------------------------|

### Returns

kStatus\_LPTMR\_Success means success. Otherwise, means failure.

#### 39.3.5.5 `lptmr_status_t LPTMR_DRV_SetTimerPeriodUs ( uint32_t instance, uint32_t us )`

This function configures the LPTMR time period while the LPTMR is working as a time counter. After the time period in microseconds, the callback function is called. This function cannot be called while the LPTMR is working as a pulse counter. The value in microseconds (us) should be integer multiple of the clock source time slice. If the clock source is 1 kHz, then both 2000  $\mu$ s and 3000  $\mu$ s are valid while 2500  $\mu$ s gets the same result as the 2000  $\mu$ s, because 2500  $\mu$ s cannot be generated in 1 kHz clock source.

### Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
| <i>us</i>       | time period in microseconds.          |

### Returns

kStatus\_LPTMR\_Success means success. Otherwise, means failure.

#### 39.3.5.6 `uint32_t LPTMR_DRV_GetCurrentTimeUs ( uint32_t instance )`

This function gets the current time while operating as a time counter. This function cannot be called while operating as a pulse counter.

### Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
|-----------------|---------------------------------------|

### Returns

current time in microsecond unit.

### 39.3.5.7 `lptmr_status_t` LPTMR\_DRV\_SetPulsePeriodCount ( `uint32_t instance`, `uint32_t pulsePeriodCount` )

This function configures the pulse period of the LPTMR while working as a pulse counter. After the count of pulsePeriodValue pulse is captured, the callback function is called. This function cannot be called while operating as a time counter.

### Parameters

|                          |                                       |
|--------------------------|---------------------------------------|
| <i>instance</i>          | The LPTMR peripheral instance number. |
| <i>pulsePeriod-Count</i> | pulse period value.                   |

### Returns

`kStatus_LPTMR_Success` means success. Otherwise, means failure.

### 39.3.5.8 `uint32_t` LPTMR\_DRV\_GetCurrentPulseCount ( `uint32_t instance` )

This function gets the current pulse count captured on the pulse input pin. This function cannot be called while operating as a time counter.

### Parameters

|                 |                                       |
|-----------------|---------------------------------------|
| <i>instance</i> | The LPTMR peripheral instance number. |
|-----------------|---------------------------------------|

### Returns

pulse count captured on the pulse input pin.

### 39.3.5.9 `lptmr_status_t` LPTMR\_DRV\_InstallCallback ( `uint32_t instance`, `lptmr_callback_t userCallback` )

This function installs the user-defined callback in the LPTMR module. When an LPTMR interrupt request is served, the callback is executed inside the ISR.

## LPTMR Peripheral driver

### Parameters

|                     |                                 |
|---------------------|---------------------------------|
| <i>instance</i>     | LPTMR instance ID.              |
| <i>userCallback</i> | User-defined callback function. |

### Returns

kStatus\_LPTMR\_Success means success. Otherwise, means failure.

### 39.3.5.10 void LPTMR\_DRV\_IRQHandler ( uint32\_t *instance* )

This function is the driver-defined ISR in the LPTMR module. It includes the process for interrupt mode defined by the driver. Currently, it is called inside the system-defined ISR.

### Parameters

|                 |                    |
|-----------------|--------------------|
| <i>instance</i> | LPTMR instance ID. |
|-----------------|--------------------|

## Chapter 40

# Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

### 40.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the Low Power Universal Asynchronous Receiver/Transmitter (LPUART) block of Kinetis devices.

#### Modules

- [LPUART HAL driver](#)
- [LPUART Peripheral driver](#)
- [LPUART Type Definitions](#)

## LPUART HAL driver

### 40.2 LPUART HAL driver

#### 40.2.1 Overview

This section describes the programming interface of the LPUART HAL driver.

#### Data Structures

- struct [lpuart\\_idle\\_line\\_config\\_t](#)  
*Structure for idle line configuration settings. [More...](#)*

#### Enumerations

- enum [lpuart\\_status\\_t](#)  
*Error codes for the LPUART driver.*
- enum [lpuart\\_stop\\_bit\\_count\\_t](#) {  
[kLpuartOneStopBit](#) = 0x0U,  
[kLpuartTwoStopBit](#) = 0x1U }  
*LPUART number of stop bits.*
- enum [lpuart\\_parity\\_mode\\_t](#) {  
[kLpuartParityDisabled](#) = 0x0U,  
[kLpuartParityEven](#) = 0x2U,  
[kLpuartParityOdd](#) = 0x3U }  
*LPUART parity mode.*
- enum [lpuart\\_bit\\_count\\_per\\_char\\_t](#) {  
[kLpuart8BitsPerChar](#) = 0x0U,  
[kLpuart9BitsPerChar](#) = 0x1U,  
[kLpuart10BitsPerChar](#) = 0x2U }  
*LPUART number of bits in a character.*
- enum [lpuart\\_operation\\_config\\_t](#) {  
[kLpuartOperates](#) = 0x0U,  
[kLpuartStops](#) = 0x1U }  
*LPUART operation configuration constants.*
- enum [lpuart\\_wakeup\\_method\\_t](#) {  
[kLpuartIdleLineWake](#) = 0x0U,  
[kLpuartAddrMarkWake](#) = 0x1U }  
*LPUART wakeup from standby method constants.*
- enum [lpuart\\_idle\\_line\\_select\\_t](#) {  
[kLpuartIdleLineAfterStartBit](#) = 0x0U,  
[kLpuartIdleLineAfterStopBit](#) = 0x1U }  
*LPUART idle line detect selection types.*
- enum [lpuart\\_break\\_char\\_length\\_t](#) {  
[kLpuartBreakChar10BitMinimum](#) = 0x0U,  
[kLpuartBreakChar13BitMinimum](#) = 0x1U }  
*LPUART break character length settings for transmit/detect.*

- enum `lpuart_singlewire_txdir_t` {  
`kLpuartSinglewireTxdirIn = 0x0U,`  
`kLpuartSinglewireTxdirOut = 0x1U }`  
*LPUART single-wire mode TX direction.*

## LPUART Common Configurations

- void [LPUART\\_HAL\\_Init](#) (LPUART\_Type \*base)  
*Initializes the LPUART controller to known state.*
- static void [LPUART\\_HAL\\_SetTransmitterCmd](#) (LPUART\_Type \*base, bool enable)  
*Enables/disables the LPUART transmitter.*
- static bool [LPUART\\_HAL\\_GetTransmitterCmd](#) (LPUART\_Type \*base)  
*Gets the LPUART transmitter enabled/disabled configuration.*
- static void [LPUART\\_HAL\\_SetReceiverCmd](#) (LPUART\_Type \*base, bool enable)  
*Enables/disables the LPUART receiver.*
- static bool [LPUART\\_HAL\\_GetReceiverCmd](#) (LPUART\_Type \*base)  
*Gets the LPUART receiver enabled/disabled configuration.*
- [lpuart\\_status\\_t](#) [LPUART\\_HAL\\_SetBaudRate](#) (LPUART\_Type \*base, uint32\_t sourceClockInHz, uint32\_t desiredBaudRate)  
*Configures the LPUART baud rate.*
- static void [LPUART\\_HAL\\_SetBaudRateDivisor](#) (LPUART\_Type \*base, uint32\_t baudRateDivisor)  
*Sets the LPUART baud rate modulo divisor.*
- void [LPUART\\_HAL\\_SetBitCountPerChar](#) (LPUART\_Type \*base, [lpuart\\_bit\\_count\\_per\\_char\\_t](#) bitCountPerChar)  
*Configures the number of bits per character in the LPUART controller.*
- void [LPUART\\_HAL\\_SetParityMode](#) (LPUART\_Type \*base, [lpuart\\_parity\\_mode\\_t](#) parityModeType)  
*Configures parity mode in the LPUART controller.*
- static void [LPUART\\_HAL\\_SetStopBitCount](#) (LPUART\_Type \*base, [lpuart\\_stop\\_bit\\_count\\_t](#) stopBitCount)  
*Configures the number of stop bits in the LPUART controller.*
- static uint32\_t [LPUART\\_HAL\\_GetDataRegAddr](#) (LPUART\_Type \*base)  
*Gets the LPUART transmit/receive data register address.*

## LPUART Interrupts and DMA

- void [LPUART\\_HAL\\_SetIntMode](#) (LPUART\_Type \*base, [lpuart\\_interrupt\\_t](#) interrupt, bool enable)  
*Configures the LPUART module interrupts to enable/disable various interrupt sources.*
- bool [LPUART\\_HAL\\_GetIntMode](#) (LPUART\_Type \*base, [lpuart\\_interrupt\\_t](#) interrupt)  
*Returns whether the LPUART module interrupts is enabled/disabled.*

## LPUART Transfer Functions

- static void [LPUART\\_HAL\\_Putchar](#) (LPUART\_Type \*base, uint8\_t data)  
*Sends the LPUART 8-bit character.*

## LPUART HAL driver

- void [LPUART\\_HAL\\_Putchar9](#) (LPUART\_Type \*base, uint16\_t data)  
*Sends the LPUART 9-bit character.*
- [lpuart\\_status\\_t](#) [LPUART\\_HAL\\_Putchar10](#) (LPUART\_Type \*base, uint16\_t data)  
*Sends the LPUART 10-bit character.*
- static void [LPUART\\_HAL\\_Getchar](#) (LPUART\_Type \*base, uint8\_t \*readData)  
*Gets the LPUART 8-bit character.*
- void [LPUART\\_HAL\\_Getchar9](#) (LPUART\_Type \*base, uint16\_t \*readData)  
*Gets the LPUART 9-bit character.*
- void [LPUART\\_HAL\\_Getchar10](#) (LPUART\_Type \*base, uint16\_t \*readData)  
*Gets the LPUART 10-bit character.*
- void [LPUART\\_HAL\\_SendDataPolling](#) (LPUART\_Type \*base, const uint8\_t \*txBuff, uint32\_t txSize)  
*Sends out multiple bytes of data using the polling method.*
- [lpuart\\_status\\_t](#) [LPUART\\_HAL\\_ReceiveDataPolling](#) (LPUART\_Type \*base, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Receives multiple bytes of data using the polling method.*

## LPUART Status Flags

- bool [LPUART\\_HAL\\_GetStatusFlag](#) (LPUART\_Type \*base, [lpuart\\_status\\_flag\\_t](#) statusFlag)  
*LPUART get status flag.*
- [lpuart\\_status\\_t](#) [LPUART\\_HAL\\_ClearStatusFlag](#) (LPUART\_Type \*base, [lpuart\\_status\\_flag\\_t](#) statusFlag)  
*LPUART clears an individual status flag (see [lpuart\\_status\\_flag\\_t](#) for list of status bits).*

## LPUART Special Feature Configurations

- static void [LPUART\\_HAL\\_SetIdleChar](#) (LPUART\_Type \*base, [lpuart\\_idle\\_char\\_t](#) idleConfig)  
*Configures the number of idle characters that must be received before the IDLE flag is set.*
- static [lpuart\\_idle\\_char\\_t](#) [LPUART\\_HAL\\_GetIdleChar](#) (LPUART\_Type \*base)  
*Gets the configuration of the number of idle characters that must be received before the IDLE flag is set.*
- static bool [LPUART\\_HAL\\_IsCurrentDataWithNoise](#) (LPUART\_Type \*base)  
*Checks whether the current data word was received with noise.*
- static bool [LPUART\\_HAL\\_IsCurrentDataWithFrameError](#) (LPUART\_Type \*base)  
*Checks whether the current data word was received with frame error.*
- static void [LPUART\\_HAL\\_SetTxSpecialChar](#) (LPUART\_Type \*base, uint8\_t specialChar)  
*Indicates a break or that the idle character is to be transmitted instead of the contents in DATA[T9:T0].*
- static bool [LPUART\\_HAL\\_IsCurrentDataWithParityError](#) (LPUART\_Type \*base)  
*Checks whether the current data word was received with parity error.*
- static bool [LPUART\\_HAL\\_IsReceiveBufferEmpty](#) (LPUART\_Type \*base)  
*Checks whether the receive buffer is empty.*
- static bool [LPUART\\_HAL\\_WasPreviousReceiverStateIdle](#) (LPUART\_Type \*base)  
*Checks whether the previous BUS state was idle before this byte is received.*
- static void [LPUART\\_HAL\\_SetWaitModeOperation](#) (LPUART\_Type \*base, [lpuart\\_operation\\_config\\_t](#) mode)  
*Configures the LPUART operation in wait mode (operates or stops operations in wait mode).*
- static [lpuart\\_operation\\_config\\_t](#) [LPUART\\_HAL\\_GetWaitModeOperation](#) (LPUART\_Type \*base)  
*Gets the LPUART operation in wait mode (operates or stops operations in wait mode).*

- void **LPUART\_HAL\_SetLoopbackCmd** (LPUART\_Type \*base, bool enable)  
*Configures the LPUART loopback operation (enables/disables the loopback operation).*
- void **LPUART\_HAL\_SetSingleWireCmd** (LPUART\_Type \*base, bool enable)  
*Configures the LPUART single-wire operation (enables/disables the single-wire mode).*
- static void **LPUART\_HAL\_SetTxdirInSinglewireMode** (LPUART\_Type \*base, **lpuart\_singlewire\_t** direction)  
*Configures the LPUART transmit direction while in single-wire mode.*
- **lpuart\_status\_t** **LPUART\_HAL\_SetReceiverInStandbyMode** (LPUART\_Type \*base)  
*Places the LPUART receiver in standby mode.*
- static void **LPUART\_HAL\_PutReceiverInNormalMode** (LPUART\_Type \*base)  
*Places the LPUART receiver in a normal mode (disable standby mode operation).*
- static bool **LPUART\_HAL\_IsReceiverInStandby** (LPUART\_Type \*base)  
*Checks whether the LPUART receiver is in a standby mode.*
- static void **LPUART\_HAL\_SetReceiverWakeupMode** (LPUART\_Type \*base, **lpuart\_wakeup\_method\_t** method)  
*LPUART receiver wakeup method (idle line or addr-mark) from standby mode.*
- static **lpuart\_wakeup\_method\_t** **LPUART\_HAL\_GetReceiverWakeupMode** (LPUART\_Type \*base)  
*Gets the LPUART receiver wakeup method (idle line or addr-mark) from standby mode.*
- void **LPUART\_HAL\_SetIdleLineDetect** (LPUART\_Type \*base, const **lpuart\_idle\_line\_config\_t** \*config)  
*LPUART idle-line detect operation configuration (idle line bit-count start and wake up affect on IDLE status bit).*
- static void **LPUART\_HAL\_SetBreakCharTransmitLength** (LPUART\_Type \*base, **lpuart\_break\_char\_length\_t** length)  
*LPUART break character transmit length configuration.*
- static void **LPUART\_HAL\_SetBreakCharDetectLength** (LPUART\_Type \*base, **lpuart\_break\_char\_length\_t** length)  
*LPUART break character detect length configuration.*
- static void **LPUART\_HAL\_QueueBreakCharToSend** (LPUART\_Type \*base, bool enable)  
*LPUART transmit sends break character configuration.*
- static void **LPUART\_HAL\_SetMatchAddressMode** (LPUART\_Type \*base, **lpuart\_match\_config\_t** config)  
*LPUART configures match address mode control.*
- void **LPUART\_HAL\_SetMatchAddressReg1** (LPUART\_Type \*base, bool enable, uint8\_t value)  
*Configures address match register 1.*
- void **LPUART\_HAL\_SetMatchAddressReg2** (LPUART\_Type \*base, bool enable, uint8\_t value)  
*Configures address match register 2.*
- static void **LPUART\_HAL\_SetSendMsbFirstCmd** (LPUART\_Type \*base, bool enable)  
*LPUART sends the MSB first configuration.*
- static void **LPUART\_HAL\_SetReceiveResyncCmd** (LPUART\_Type \*base, bool enable)  
*LPUART enable/disable re-sync of received data configuration.*

## LPUART HAL driver

### 40.2.2 Data Structure Documentation

#### 40.2.2.1 struct lpuart\_idle\_line\_config\_t

##### Data Fields

- unsigned `idleLineType`: 1  
*ILT, Idle bit count start: 0 - after start bit (default), 1 - after stop bit.*
- unsigned `rxWakeIdleDetect`: 1  
*RWUID, Receiver Wake Up Idle Detect.*

#### 40.2.2.1.0.146 Field Documentation

##### 40.2.2.1.0.146.1 unsigned lpuart\_idle\_line\_config\_t::rxWakeIdleDetect

IDLE status bit operation during receive standbyControls whether idle character that wakes up receiver will also set IDLE status bit 0 - IDLE status bit doesn't get set (default), 1 - IDLE status bit gets set

### 40.2.3 Enumeration Type Documentation

#### 40.2.3.1 enum lpuart\_status\_t

#### 40.2.3.2 enum lpuart\_stop\_bit\_count\_t

Enumerator

- kLpuartOneStopBit* one stop bit
- kLpuartTwoStopBit* two stop bits

#### 40.2.3.3 enum lpuart\_parity\_mode\_t

Enumerator

- kLpuartParityDisabled* parity disabled
- kLpuartParityEven* parity enabled, type even, bit setting: PE|PT = 10
- kLpuartParityOdd* parity enabled, type odd, bit setting: PE|PT = 11

#### 40.2.3.4 enum lpuart\_bit\_count\_per\_char\_t

Enumerator

- kLpuart8BitsPerChar* 8-bit data characters
- kLpuart9BitsPerChar* 9-bit data characters
- kLpuart10BitsPerChar* 10-bit data characters

#### 40.2.3.5 enum lpuart\_operation\_config\_t

Enumerator

*kLpuartOperates* LPUART continues to operate normally.

*kLpuartStops* LPUART stops operation.

#### 40.2.3.6 enum lpuart\_wakeup\_method\_t

Enumerator

*kLpuartIdleLineWake* Idle-line wakes the LPUART receiver from standby.

*kLpuartAddrMarkWake* Addr-mark wakes LPUART receiver from standby.

#### 40.2.3.7 enum lpuart\_idle\_line\_select\_t

Enumerator

*kLpuartIdleLineAfterStartBit* LPUART idle character bit count start after start bit.

*kLpuartIdleLineAfterStopBit* LPUART idle character bit count start after stop bit.

#### 40.2.3.8 enum lpuart\_break\_char\_length\_t

The actual maximum bit times may vary depending on the LPUART instance.

Enumerator

*kLpuartBreakChar10BitMinimum* LPUART break char length 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 13 (if M10 = 1, SNBS = 1)

*kLpuartBreakChar13BitMinimum* LPUART break char length 13 bit times (if M = 0, SBNS = 0 or M10 = 0, SBNS = 1) or 14 (if M = 1, SBNS = 0 or M = 1, SBNS = 1) or 15 (if M10 = 1, SBNS = 1 or M10 = 1, SNBS = 0)

#### 40.2.3.9 enum lpuart\_singlewire\_txdirection\_t

Enumerator

*kLpuartSinglewireTxdirectionIn* LPUART Single Wire mode TXDIR input.

*kLpuartSinglewireTxdirectionOut* LPUART Single Wire mode TXDIR output.

## LPUART HAL driver

### 40.2.3.10 enum lpuart\_match\_config\_t

Enumerator

- kLpuartAddressMatchWakeup* Address Match Wakeup.
- kLpuartIdleMatchWakeup* Idle Match Wakeup.
- kLpuartMatchOnAndMatchOff* Match On and Match Off.
- kLpuartEnablesRwuOnDataMatch* Enables RWU on Data Match and Match On/Off for transmitter CTS input.

### 40.2.3.11 enum lpuart\_ir\_tx\_pulsewidth\_t

Enumerator

- kLpuartIrThreeSixteenthsWidth* 3/16 pulse
- kLpuartIrOneSixteenthWidth* 1/16 pulse
- kLpuartIrOneThirtysecondsWidth* 1/32 pulse
- kLpuartIrOneFourthWidth* 1/4 pulse

### 40.2.3.12 enum lpuart\_idle\_char\_t

Enumerator

- kLpuart\_1\_IdleChar* 1 idle character
- kLpuart\_2\_IdleChar* 2 idle character
- kLpuart\_4\_IdleChar* 4 idle character
- kLpuart\_8\_IdleChar* 8 idle character
- kLpuart\_16\_IdleChar* 16 idle character
- kLpuart\_32\_IdleChar* 32 idle character
- kLpuart\_64\_IdleChar* 64 idle character
- kLpuart\_128\_IdleChar* 128 idle character

### 40.2.3.13 enum lpuart\_cts\_source\_t

Configures the source of the CTS input.

Enumerator

- kLpuartCtsSourcePin* CTS input is the LPUART\_CTS pin.
- kLpuartCtsSourceInvertedReceiverMatch* CTS input is the inverted Receiver Match result.

#### 40.2.3.14 enum lpuart\_cts\_config\_t

Enumerator

- kLpuartCtsSampledOnEachChar* CTS input is sampled at the start of each character.
- kLpuartCtsSampledOnIdle* CTS input is sampled when the transmitter is idle.

#### 40.2.3.15 enum lpuart\_rx\_idle\_empty\_config\_t

Enumerator

- kLpuartRxidDisabled* Disable RDRF assertion due to partially filled FIFO when receiver is idle.
- kLpuartRxidEnabledFor1Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character.
- kLpuartRxidEnabledFor2Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters.
- kLpuartRxidEnabledFor4Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters.
- kLpuartRxidEnabledFor8Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters.
- kLpuartRxidEnabledFor16Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters.
- kLpuartRxidEnabledFor32Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters.
- kLpuartRxidEnabledFor64Char* Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.

#### 40.2.3.16 enum lpuart\_status\_flag\_t

This provides constants for the LPUART status flags for use in the UART functions.

Enumerator

- kLpuartTxDataRegEmpty* Transmit data register empty flag, sets when transmit buffer is empty.
- kLpuartTxComplete* Transmission complete flag, sets when transmission activity complete.
- kLpuartRxDataRegFull* Receive data register full flag, sets when the receive data buffer is full.
- kLpuartIdleLineDetect* Idle line detect flag, sets when idle line detected.
- kLpuartRxOverrun* Receive Overrun, sets when new data is received before data is read from receive register.
- kLpuartNoiseDetect* Receive takes 3 samples of each received bit. If any of these samples differ, noise flag sets
- kLpuartFrameErr* Frame error flag, sets if logic 0 was detected where stop bit expected.
- kLpuartParityErr* If parity enabled, sets upon parity error detection.
- kLpuartLineBreakDetect* LIN break detect interrupt flag, sets when LIN break char detected and LIN circuit enabled.

## LPUART HAL driver

*kLpuartRxActiveEdgeDetect* Receive pin active edge interrupt flag, sets when active edge detected.

*kLpuartRxActive* Receiver Active Flag (RAF), sets at beginning of valid start bit.

*kLpuartNoiseInCurrentWord* NOISY bit, sets if noise detected in current data word.

*kLpuartParityErrInCurrentWord* PARITYE bit, sets if noise detected in current data word.

### 40.2.3.17 enum lpuart\_interrupt\_t

Enumerator

*kLpuartIntLinBreakDetect* LIN break detect.

*kLpuartIntRxActiveEdge* Receive Active Edge.

*kLpuartIntTxDataRegEmpty* Transmit data register empty.

*kLpuartIntTxComplete* Transmission complete.

*kLpuartIntRxDataRegFull* Receiver data register full.

*kLpuartIntIdleLine* Idle line.

*kLpuartIntRxOverrun* Receiver Overrun.

*kLpuartIntNoiseErrFlag* Noise error flag.

*kLpuartIntFrameErrFlag* Framing error flag.

*kLpuartIntParityErrFlag* Parity error flag.

## 40.2.4 Function Documentation

### 40.2.4.1 void LPUART\_HAL\_Init ( LPUART\_Type \* *base* )

Parameters

|             |                      |
|-------------|----------------------|
| <i>base</i> | LPUART base pointer. |
|-------------|----------------------|

### 40.2.4.2 static void LPUART\_HAL\_SetTransmitterCmd ( LPUART\_Type \* *base*, bool *enable* ) [inline], [static]

Parameters

|               |                                             |
|---------------|---------------------------------------------|
| <i>base</i>   | LPUART base pointer.                        |
| <i>enable</i> | Enable(true) or disable(false) transmitter. |

**40.2.4.3 static bool LPUART\_HAL\_GetTransmitterCmd ( LPUART\_Type \* *base* )  
[inline], [static]**

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

State of LPUART transmitter enable(true)/disable(false)

**40.2.4.4 static void LPUART\_HAL\_SetReceiverCmd ( LPUART\_Type \* *base*, bool *enable* ) [inline], [static]**

Parameters

|               |                                          |
|---------------|------------------------------------------|
| <i>base</i>   | LPUART base pointer                      |
| <i>enable</i> | Enable(true) or disable(false) receiver. |

**40.2.4.5 static bool LPUART\_HAL\_GetReceiverCmd ( LPUART\_Type \* *base* )  
[inline], [static]**

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

State of LPUART receiver enable(true)/disable(false)

**40.2.4.6 lpuart\_status\_t LPUART\_HAL\_SetBaudRate ( LPUART\_Type \* *base*, uint32\_t *sourceClockInHz*, uint32\_t *desiredBaudRate* )**

In some LPUART instances the user must disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

## LPUART HAL driver

### Parameters

|                         |                                  |
|-------------------------|----------------------------------|
| <i>base</i>             | LPUART base pointer.             |
| <i>sourceClockIn-Hz</i> | LPUART source input clock in Hz. |
| <i>desiredBaud-Rate</i> | LPUART desired baud rate.        |

### Returns

An error code or `kStatus_Success`

**40.2.4.7** `static void LPUART_HAL_SetBaudRateDivisor ( LPUART_Type * base, uint32_t baudRateDivisor ) [inline], [static]`

### Parameters

|                         |                                     |
|-------------------------|-------------------------------------|
| <i>base</i>             | LPUART base pointer.                |
| <i>baudRate-Divisor</i> | The baud rate modulo division "SBR" |

**40.2.4.8** `void LPUART_HAL_SetBitCountPerChar ( LPUART_Type * base, lpuart_bit_count_per_char_t bitCountPerChar )`

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

### Parameters

|                         |                                                                         |
|-------------------------|-------------------------------------------------------------------------|
| <i>base</i>             | LPUART base pointer.                                                    |
| <i>bitCountPer-Char</i> | Number of bits per char (8, 9, or 10, depending on the LPUART instance) |

**40.2.4.9** `void LPUART_HAL_SetParityMode ( LPUART_Type * base, lpuart_parity_mode_t parityModeType )`

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|                             |                                                                      |
|-----------------------------|----------------------------------------------------------------------|
| <i>base</i>                 | LPUART base pointer.                                                 |
| <i>parityMode-<br/>Type</i> | Parity mode (enabled, disable, odd, even - see parity_mode_t struct) |

**40.2.4.10 static void LPUART\_HAL\_SetStopBitCount ( LPUART\_Type \* *base*, lpuart\_stop\_bit\_count\_t *stopBitCount* ) [inline], [static]**

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|                     |                                                                   |
|---------------------|-------------------------------------------------------------------|
| <i>base</i>         | LPUART base pointer.                                              |
| <i>stopBitCount</i> | Number of stop bits (1 or 2 - see lpuart_stop_bit_count_t struct) |

Returns

An error code (an unsupported setting in some LPUARTs) or kStatus\_Success

**40.2.4.11 static uint32\_t LPUART\_HAL\_GetDataRegAddr ( LPUART\_Type \* *base* ) [inline], [static]**

Parameters

|             |                      |
|-------------|----------------------|
| <i>base</i> | LPUART base pointer. |
|-------------|----------------------|

Returns

LPUART transmit/receive data register address.

**40.2.4.12 void LPUART\_HAL\_SetIntMode ( LPUART\_Type \* *base*, lpuart\_interrupt\_t *interrupt*, bool *enable* )**

## LPUART HAL driver

Parameters

|                  |                                      |
|------------------|--------------------------------------|
| <i>base</i>      | LPUART module base pointer.          |
| <i>interrupt</i> | LPUART interrupt configuration data. |
| <i>enable</i>    | true: enable, false: disable.        |

### 40.2.4.13 `bool LPUART_HAL_GetIntMode ( LPUART_Type * base, lpuart_interrupt_t interrupt )`

Parameters

|                  |                                      |
|------------------|--------------------------------------|
| <i>base</i>      | LPUART module base pointer.          |
| <i>interrupt</i> | LPUART interrupt configuration data. |

Returns

true: enable, false: disable.

### 40.2.4.14 `static void LPUART_HAL_Putchar ( LPUART_Type * base, uint8_t data )` `[inline], [static]`

Parameters

|             |                      |
|-------------|----------------------|
| <i>base</i> | LPUART Instance      |
| <i>data</i> | data to send (8-bit) |

### 40.2.4.15 `void LPUART_HAL_Putchar9 ( LPUART_Type * base, uint16_t data )`

Parameters

|             |                      |
|-------------|----------------------|
| <i>base</i> | LPUART Instance      |
| <i>data</i> | data to send (9-bit) |

### 40.2.4.16 `lpuart_status_t LPUART_HAL_Putchar10 ( LPUART_Type * base, uint16_t data )`

Note that this feature is available on select LPUART instances.

Parameters

|             |                       |
|-------------|-----------------------|
| <i>base</i> | LPUART Instance       |
| <i>data</i> | data to send (10-bit) |

Returns

An error code or kStatus\_Success

**40.2.4.17 static void LPUART\_HAL\_Getchar ( LPUART\_Type \* *base*, uint8\_t \* *readData* )  
[inline], [static]**

Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>base</i>     | LPUART base pointer            |
| <i>readData</i> | Data read from receive (8-bit) |

**40.2.4.18 void LPUART\_HAL\_Getchar9 ( LPUART\_Type \* *base*, uint16\_t \* *readData* )**

Parameters

|                 |                                |
|-----------------|--------------------------------|
| <i>base</i>     | LPUART base pointer            |
| <i>readData</i> | Data read from receive (9-bit) |

**40.2.4.19 void LPUART\_HAL\_Getchar10 ( LPUART\_Type \* *base*, uint16\_t \* *readData* )**

Parameters

|                 |                                 |
|-----------------|---------------------------------|
| <i>base</i>     | LPUART base pointer             |
| <i>readData</i> | Data read from receive (10-bit) |

**40.2.4.20 void LPUART\_HAL\_SendDataPolling ( LPUART\_Type \* *base*, const uint8\_t \* *txBuff*, uint32\_t *txSize* )**

This function only supports 8-bit transaction.

## LPUART HAL driver

Parameters

|               |                                                     |
|---------------|-----------------------------------------------------|
| <i>base</i>   | LPUART module base pointer.                         |
| <i>txBuff</i> | The buffer pointer which saves the data to be sent. |
| <i>txSize</i> | Size of data to be sent in unit of byte.            |

### 40.2.4.21 `lpuart_status_t LPUART_HAL_ReceiveDataPolling ( LPUART_Type * base, uint8_t * rxBuff, uint32_t rxSize )`

This function only supports 8-bit transaction.

Parameters

|               |                                                         |
|---------------|---------------------------------------------------------|
| <i>base</i>   | LPUART module base pointer.                             |
| <i>rxBuff</i> | The buffer pointer which saves the data to be received. |
| <i>rxSize</i> | Size of data need to be received in unit of byte.       |

Returns

Whether the transaction is success or receive overrun.

### 40.2.4.22 `bool LPUART_HAL_GetStatusFlag ( LPUART_Type * base, lpuart_status_flag_t statusFlag )`

Parameters

|                   |                          |
|-------------------|--------------------------|
| <i>base</i>       | LPUART base pointer      |
| <i>statusFlag</i> | The status flag to query |

Returns

Whether the current status flag is set(true) or not(false).

### 40.2.4.23 `lpuart_status_t LPUART_HAL_ClearStatusFlag ( LPUART_Type * base, lpuart_status_flag_t statusFlag )`

Parameters

|                   |                                     |
|-------------------|-------------------------------------|
| <i>base</i>       | LPUART base pointer                 |
| <i>statusFlag</i> | Desired LPUART status flag to clear |

Returns

An error code or kStatus\_Success

**40.2.4.24 static void LPUART\_HAL\_SetIdleChar ( LPUART\_Type \* *base*,  
lpuart\_idle\_char\_t *idleConfig* ) [inline], [static]**

Parameters

|                   |                               |
|-------------------|-------------------------------|
| <i>base</i>       | LPUART base pointer           |
| <i>idleConfig</i> | Idle characters configuration |

**40.2.4.25 static lpuart\_idle\_char\_t LPUART\_HAL\_GetIdleChar ( LPUART\_Type \* *base* )  
[inline], [static]**

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

idle characters configuration

**40.2.4.26 static bool LPUART\_HAL\_IsCurrentDataWithNoise ( LPUART\_Type \* *base* )  
[inline], [static]**

Parameters

|             |                      |
|-------------|----------------------|
| <i>base</i> | LPUART base pointer. |
|-------------|----------------------|

## LPUART HAL driver

### Returns

The status of the NOISY bit in the LPUART extended data register

**40.2.4.27** `static bool LPUART_HAL_IsCurrentDataWithFrameError ( LPUART_Type * base ) [inline], [static]`

### Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

### Returns

The status of the FRETSC bit in the LPUART extended data register

**40.2.4.28** `static void LPUART_HAL_SetTxSpecialChar ( LPUART_Type * base, uint8_t specialChar ) [inline], [static]`

### Parameters

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>base</i>        | LPUART base pointer                                                                                                   |
| <i>specialChar</i> | T9 is used to indicate a break character when 0 an idle character when 1, the contents of DATA[T8:T0] should be zero. |

**40.2.4.29** `static bool LPUART_HAL_IsCurrentDataWithParityError ( LPUART_Type * base ) [inline], [static]`

### Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

### Returns

The status of the PARITYE bit in the LPUART extended data register

**40.2.4.30** `static bool LPUART_HAL_IsReceiveBufferEmpty ( LPUART_Type * base ) [inline], [static]`

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

TRUE if the receive-buffer is empty, else FALSE.

**40.2.4.31 static bool LPUART\_HAL\_WasPreviousReceiverStateIdle ( LPUART\_Type \* *base* ) [inline], [static]**

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

TRUE if the previous BUS state was IDLE, else FALSE.

**40.2.4.32 static void LPUART\_HAL\_SetWaitModeOperation ( LPUART\_Type \* *base*, lpuart\_operation\_config\_t *mode* ) [inline], [static]**

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|             |                                                                         |
|-------------|-------------------------------------------------------------------------|
| <i>base</i> | LPUART base pointer                                                     |
| <i>mode</i> | LPUART wait mode operation - operates or stops to operate in wait mode. |

**40.2.4.33 static lpuart\_operation\_config\_t LPUART\_HAL\_GetWaitModeOperation ( LPUART\_Type \* *base* ) [inline], [static]**

Parameters

---

## LPUART HAL driver

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

LPUART wait mode operation configuration

- kLpuartOperates or KLpuartStops in wait mode

### 40.2.4.34 void LPUART\_HAL\_SetLoopbackCmd ( LPUART\_Type \* *base*, bool *enable* )

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|               |                                                    |
|---------------|----------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                |
| <i>enable</i> | LPUART loopback mode - disabled (0) or enabled (1) |

### 40.2.4.35 void LPUART\_HAL\_SetSingleWireCmd ( LPUART\_Type \* *base*, bool *enable* )

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|               |                                                    |
|---------------|----------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                |
| <i>enable</i> | LPUART loopback mode - disabled (0) or enabled (1) |

### 40.2.4.36 static void LPUART\_HAL\_SetTxdirInSinglewireMode ( LPUART\_Type \* *base*, lpuart\_singlewire\_txdir\_t *direction* ) [inline], [static]

Parameters

|                  |                                                         |
|------------------|---------------------------------------------------------|
| <i>base</i>      | LPUART base pointer                                     |
| <i>direction</i> | LPUART single-wire transmit direction - input or output |

**40.2.4.37** `lpuart_status_t LPUART_HAL_SetReceiverInStandbyMode ( LPUART_Type * base )`

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

Error code or `kStatus_Success`

**40.2.4.38** `static void LPUART_HAL_PutReceiverInNormalMode ( LPUART_Type * base ) [inline], [static]`

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

**40.2.4.39** `static bool LPUART_HAL_IsReceiverInStandby ( LPUART_Type * base ) [inline], [static]`

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

LPUART in normal mode (0) or standby (1)

**40.2.4.40** `static void LPUART_HAL_SetReceiverWakeupMode ( LPUART_Type * base, lpuart_wakeup_method_t method ) [inline], [static]`

## LPUART HAL driver

Parameters

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                                    |
| <i>method</i> | LPUART wakeup method: 0 - Idle-line wake (default), 1 - addr-mark wake |

**40.2.4.41 static lpuart\_wakeup\_method\_t LPUART\_HAL\_GetReceiverWakeupMode ( LPUART\_Type \* *base* ) [inline], [static]**

Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

Returns

LPUART wakeup method: kLpuartIdleLineWake: 0 - Idle-line wake (default), kLpuartAddrMarkWake: 1 - addr-mark wake

**40.2.4.42 void LPUART\_HAL\_SetIdleLineDetect ( LPUART\_Type \* *base*, const lpuart\_idle\_line\_config\_t \* *config* )**

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

|               |                                                          |
|---------------|----------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                      |
| <i>config</i> | LPUART configuration data for idle line detect operation |

**40.2.4.43 static void LPUART\_HAL\_SetBreakCharTransmitLength ( LPUART\_Type \* *base*, lpuart\_break\_char\_length\_t *length* ) [inline], [static]**

In some LPUART instances, the user should disable the transmitter before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

Parameters

---

|               |                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                                                                 |
| <i>length</i> | LPUART break character length setting: 0 - minimum 10-bit times (default), 1 - minimum 13-bit times |

**40.2.4.44** `static void LPUART_HAL_SetBreakCharDetectLength ( LPUART_Type * base, lpuart_break_char_length_t length ) [inline], [static]`

Parameters

|               |                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                                                                 |
| <i>length</i> | LPUART break character length setting: 0 - minimum 10-bit times (default), 1 - minimum 13-bit times |

**40.2.4.45** `static void LPUART_HAL_QueueBreakCharToSend ( LPUART_Type * base, bool enable ) [inline], [static]`

Parameters

|               |                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                                                                  |
| <i>enable</i> | LPUART normal/queue break char - disabled (normal mode, default: 0) or enabled (queue break char: 1) |

**40.2.4.46** `static void LPUART_HAL_SetMatchAddressMode ( LPUART_Type * base, lpuart_match_config_t config ) [inline], [static]`

Parameters

|               |                                                    |
|---------------|----------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                |
| <i>config</i> | MATCFG: Configures the match addressing mode used. |

**40.2.4.47** `void LPUART_HAL_SetMatchAddressReg1 ( LPUART_Type * base, bool enable, uint8_t value )`

The MAEN bit must be cleared before configuring the MA value. Therefore, the enable/disable and set value must be included inside one function.

## LPUART HAL driver

### Parameters

|               |                                                              |
|---------------|--------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                          |
| <i>enable</i> | Match address model enable (true)/disable (false)            |
| <i>value</i>  | Match address value to program into match address register 1 |

#### 40.2.4.48 void LPUART\_HAL\_SetMatchAddressReg2 ( LPUART\_Type \* *base*, bool *enable*, uint8\_t *value* )

The MAEN bit must be cleared before configuring MA value. Therefore, the enable/disable and set value must be included inside one function.

### Parameters

|               |                                                              |
|---------------|--------------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                          |
| <i>enable</i> | Match address model enable (true)/disable (false)            |
| <i>value</i>  | Match address value to program into match address register 2 |

#### 40.2.4.49 static void LPUART\_HAL\_SetSendMsbFirstCmd ( LPUART\_Type \* *base*, bool *enable* ) [inline], [static]

In some LPUART instances, the user should disable the transmitter/receiver before calling this function. Generally, this may be applied to all LPUARTs to ensure safe operation.

### Parameters

|               |                                                       |
|---------------|-------------------------------------------------------|
| <i>base</i>   | LPUART base pointer                                   |
| <i>enable</i> | false - LSB (default, disabled), true - MSB (enabled) |

#### 40.2.4.50 static void LPUART\_HAL\_SetReceiveResyncCmd ( LPUART\_Type \* *base*, bool *enable* ) [inline], [static]

### Parameters

|             |                     |
|-------------|---------------------|
| <i>base</i> | LPUART base pointer |
|-------------|---------------------|

|               |                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i> | re-sync of received data word configuration: true - re-sync of received data word (default) false - disable the re-sync |
|---------------|-------------------------------------------------------------------------------------------------------------------------|

## LPUART Peripheral driver

### 40.3 LPUART Peripheral driver

#### 40.3.1 Overview

This section describes the programming interface of the LPUART Peripheral driver.

#### Data Structures

- struct [lpuart\\_dma\\_state\\_t](#)  
*Runtime state structure for UART driver with DMA. [More...](#)*
- struct [lpuart\\_dma\\_user\\_config\\_t](#)  
*LPUART configuration structure. [More...](#)*
- struct [lpuart\\_state\\_t](#)  
*Runtime state of the LPUART driver. [More...](#)*
- struct [lpuart\\_user\\_config\\_t](#)  
*LPUART configuration structure. [More...](#)*
- struct [lpuart\\_edma\\_state\\_t](#)  
*Runtime state structure for UART driver with DMA. [More...](#)*
- struct [lpuart\\_edma\\_user\\_config\\_t](#)  
*LPUART configuration structure. [More...](#)*

#### Typedefs

- typedef void(\* [lpuart\\_rx\\_callback\\_t](#))(uint32\_t instance, void \*lpuartState)  
*LPUART receive callback function type.*
- typedef void(\* [lpuart\\_tx\\_callback\\_t](#))(uint32\_t instance, void \*lpuartState)  
*UART transmit callback function type.*

#### Variables

- LPUART\_Type \*const [g\\_lpuartBase](#) [LPUART\_INSTANCE\_COUNT]  
*Table of base addresses for LPUART instances.*
- LPUART\_Type \*const [g\\_lpuartBase](#) [LPUART\_INSTANCE\_COUNT]  
*Table of base addresses for LPUART instances.*
- const IRQn\_Type [g\\_lpuartRxTxIrqId](#) [LPUART\_INSTANCE\_COUNT]  
*Table to save LPUART IRQ enumeration numbers defined in the CMSIS header file.*
- LPUART\_Type \*const [g\\_lpuartBase](#) [LPUART\_INSTANCE\_COUNT]  
*Table of base addresses for LPUART instances.*

#### LPUART DMA Driver

- [lpuart\\_status\\_t](#) LPUART\_DRV\_DmaInit (uint32\_t instance, [lpuart\\_dma\\_state\\_t](#) \*lpuartDmaStatePtr, const [lpuart\\_dma\\_user\\_config\\_t](#) \*lpuartUserConfig)  
*Initializes an LPUART instance to work with DMA.*
- [lpuart\\_status\\_t](#) LPUART\_DRV\_DmaDeinit (uint32\_t instance)

- Shuts down the LPUART.*

  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaSendDataBlocking](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize, uint32\_t timeout)
  - Sends (transmits) data out through the LPUART-DMA module using a blocking method.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaSendData](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)
  - Sends (transmits) data through the LPUART-DMA module using a non-blocking method.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaGetTransmitStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)
  - Returns whether the previous LPUART-DMA transmit has finished.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaAbortSendingData](#) (uint32\_t instance)
  - Terminates a non-blocking LPUART-DMA transmission early.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaReceiveDataBlocking](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize, uint32\_t timeout)
  - Gets (receives) data from the LPUART-DMA module using a blocking method.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaReceiveData](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)
  - Gets (receives) data from the LPUART-DMA module using a non-blocking method.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaGetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)
  - Returns whether the previous LPUART-DMA receive is complete.*
  - [lpuart\\_status\\_t LPUART\\_DRV\\_DmaAbortReceivingData](#) (uint32\_t instance)
  - Terminates a non-blocking LPUART-DMA receive early.*

## LPUART Driver

- [lpuart\\_status\\_t LPUART\\_DRV\\_Init](#) (uint32\_t instance, [lpuart\\_state\\_t](#) \*lpuartStatePtr, const [lpuart\\_user\\_config\\_t](#) \*lpuartUserConfig)
- Initializes an LPUART operation instance.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_Deinit](#) (uint32\_t instance)
- Shuts down the LPUART by disabling interrupts and transmitter/receiver.*
- [lpuart\\_rx\\_callback\\_t LPUART\\_DRV\\_InstallRxCallback](#) (uint32\_t instance, [lpuart\\_rx\\_callback\\_t](#) function, uint8\_t \*rxBuff, void \*callbackParam, bool alwaysEnableRxIrq)
- Installs callback function for the LPUART receive.*
- [lpuart\\_tx\\_callback\\_t LPUART\\_DRV\\_InstallTxCallback](#) (uint32\_t instance, [lpuart\\_tx\\_callback\\_t](#) function, uint8\_t \*txBuff, void \*callbackParam)
- Installs callback function for the LPUART transmit.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_SendDataBlocking](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize, uint32\_t timeout)
- Sends data out through the LPUART module using a blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_SendData](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)
- Sends data out through the LPUART module using a non-blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_GetTransmitStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)
- Returns whether the previous transmit is complete.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_AbortSendingData](#) (uint32\_t instance)
- Terminates a non-blocking transmission early.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_ReceiveDataBlocking](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t

## LPUART Peripheral driver

rxSize, uint32\_t timeout)

*Gets data from the LPUART module by using a blocking method.*

- [lpuart\\_status\\_t LPUART\\_DRV\\_ReceiveData](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Gets data from the LPUART module by using a non-blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_GetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Returns whether the previous receive is complete.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_AbortReceivingData](#) (uint32\_t instance)  
*Terminates a non-blocking receive early.*

## LPUART DMA Driver

- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaInit](#) (uint32\_t instance, [lpuart\\_edma\\_state\\_t](#) \*lpuartEdmaStatePtr, const [lpuart\\_edma\\_user\\_config\\_t](#) \*lpuartUserConfig)  
*Initializes an LPUART instance to work with DMA.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaDeinit](#) (uint32\_t instance)  
*Shuts down the LPUART.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaSendDataBlocking](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize, uint32\_t timeout)  
*Sends (transmits) data out through the LPUART-DMA module using a blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaSendData](#) (uint32\_t instance, const uint8\_t \*txBuff, uint32\_t txSize)  
*Sends (transmits) data through the LPUART-DMA module using a non-blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaGetTransmitStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Returns whether the previous LPUART-DMA transmit has finished.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaAbortSendingData](#) (uint32\_t instance)  
*Terminates a non-blocking LPUART-DMA transmission early.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaReceiveDataBlocking](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize, uint32\_t timeout)  
*Gets (receives) data from the LPUART-DMA module using a blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaReceiveData](#) (uint32\_t instance, uint8\_t \*rxBuff, uint32\_t rxSize)  
*Gets (receives) data from the LPUART-DMA module using a non-blocking method.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaGetReceiveStatus](#) (uint32\_t instance, uint32\_t \*bytesRemaining)  
*Returns whether the previous LPUART-DMA receive is complete.*
- [lpuart\\_status\\_t LPUART\\_DRV\\_EdmaAbortReceivingData](#) (uint32\_t instance)  
*Terminates a non-blocking LPUART-DMA receive early.*

## 40.3.2 Data Structure Documentation

### 40.3.2.1 struct lpuart\_dma\_state\_t

#### Data Fields

- volatile bool [isTxBusy](#)  
*True if there is an active transmit.*

- volatile bool [isRxBusy](#)  
*True if there is an active receive.*
- volatile bool [isTxBlocking](#)  
*True if transmit is blocking transaction.*
- volatile bool [isRxBlocking](#)  
*True if receive is blocking transaction.*

*number of stop bits, 1 stop bit (default) or 2 stop bits*
- [lpuart\\_bit\\_count\\_per\\_char\\_t bitCountPerChar](#)  
*number of bits, 8-bit (default) or 9-bit in a char (up to 10-bits in some LPUART instances).*

## LPUART Peripheral driver

### 40.3.2.2.0.148 Field Documentation

#### 40.3.2.2.0.148.1 lpuart\_bit\_count\_per\_char\_t lpuart\_dma\_user\_config\_t::bitCountPerChar

### 40.3.2.3 struct lpuart\_state\_t

Note that the caller must provide memory for the driver state structures during initialization because the driver does not statically allocate memory.

#### Data Fields

- `uint8_t txFifoEntryCount`  
*Number of data word entries in transmit FIFO.*
- `const uint8_t * txBuff`  
*The buffer of data being sent.*
- `uint8_t * rxBuff`  
*The buffer of received data.*
- `volatile size_t txSize`  
*The remaining number of bytes to be transmitted.*
- `volatile size_t rxSize`  
*The remaining number of bytes to be received.*
- `volatile bool isTxBusy`  
*True if there is an active transmit.*
- `volatile bool isRxBusy`  
*True if there is an active receive.*
- `volatile bool isTxBlocking`  
*True if transmit is blocking transaction.*
- `volatile bool isRxBlocking`  
*True if receive is blocking transaction.*
- `semaphore_t txIrqSync`  
*Used to wait for ISR to complete transmit.*
- `semaphore_t rxIrqSync`  
*Used to wait for ISR to complete receive.*
- `lpuart_rx_callback_t rxCallback`  
*Callback to invoke after receiving byte.*
- `void * rxCallbackParam`  
*Receive callback parameter pointer.*
- `lpuart_tx_callback_t txCallback`  
*Callback to invoke after transmitting byte.*
- `void * txCallbackParam`  
*Transmit callback parameter pointer.*

### 40.3.2.6 struct lpuart\_edma\_user\_config\_t

#### Data Fields

- [clock\\_lpuart\\_src\\_t clockSource](#)  
*LPUART clock source in fsl\_sim\_hal\_<device>.h.*
- uint32\_t [baudRate](#)  
*LPUART baud rate.*
- [lpuart\\_parity\\_mode\\_t parityMode](#)  
*parity mode, disabled (default), even, odd*
- [lpuart\\_stop\\_bit\\_count\\_t stopBitCount](#)  
*number of stop bits, 1 stop bit (default) or 2 stop bits*
- [lpuart\\_bit\\_count\\_per\\_char\\_t bitCountPerChar](#)  
*number of bits, 8-bit (default) or 9-bit in a char (up to 10-bits in some LPUART instances).*

**40.3.2.6.0.151 Field Documentation**

**40.3.2.6.0.151.1** `lpuart_bit_count_per_char_t lpuart_edma_user_config_t::bitCountPerChar`

**40.3.3 Typedef Documentation**

**40.3.3.1** `typedef void(* lpuart_rx_callback_t)(uint32_t instance, void *lpuartState)`

**40.3.4 Function Documentation**

**40.3.4.1** `lpuart_status_t LPUART_DRV_DmaInit ( uint32_t instance, lpuart_dma_state_t * lpuartDmaStatePtr, const lpuart_dma_user_config_t * lpuartUserConfig )`

This function initializes the run-time state structure to keep track of the on-going transfers, un-gates the clock to the LPUART module, initializes the module to user-defined settings and default settings, configures the IRQ state structure and enables the module-level interrupt to the core, and enables the LPUART module transmitter and receiver. This example shows how to set up the `lpuart_dma_state_t` and the `lpuart_user_config_t` parameters and how to call the `LPUART_DRV_DmaInit` function by passing in these parameters:

```
lpuart_user_config_t lpuartConfig;
lpuartConfig.baudRate = 9600;
lpuartConfig.bitCountPerChar = kLpuart8BitsPerChar;
lpuartConfig.parityMode = kLpuartParityDisabled;
lpuartConfig.stopBitCount = kLpuartOneStopBit;
lpuart_dma_state_t lpuartDmaState;
LPUART_DRV_DmaInit(instance, &lpuartDmaState, &lpuartConfig);
```

Parameters

|                          |                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>          | The LPUART instance number.                                                                                                                                                                                                                    |
| <i>lpuartDmaStatePtr</i> | A pointer to the LPUART driver state structure memory. The user passes in the memory for the run-time state structure. The LPUART driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>lpuartUserConfig</i>  | The user configuration structure of type <code>lpuart_user_config_t</code> . The user populates the members of this structure and passes the pointer of this structure into this function.                                                     |

Returns

An error code or `kStatus_LPUART_Success`.

**40.3.4.2** `lpuart_status_t LPUART_DRV_DmaDeinit ( uint32_t instance )`

This function disables the LPUART-DMA trigger, the transmitter, and the receiver.

## LPUART Peripheral driver

### Parameters

|                 |                             |
|-----------------|-----------------------------|
| <i>instance</i> | The LPUART instance number. |
|-----------------|-----------------------------|

### Returns

An error code or kStatus\_LPUART\_Success.

#### 40.3.4.3 `lpuart_status_t LPUART_DRV_DmaSendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout )`

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPUART instance number.                                             |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>   | The number of bytes to send.                                            |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or kStatus\_LPUART\_Success.

#### 40.3.4.4 `lpuart_status_t LPUART_DRV_DmaSendData ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize )`

### Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                     |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

### Returns

An error code or kStatus\_LPUART\_Success.

#### 40.3.4.5 `lpuart_status_t LPUART_DRV_DmaGetTransmitStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPUART module base address.                                                                            |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

Returns

Current transmit status.

Return values

|                               |                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_LPUART_TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

**40.3.4.6 lpuart\_status\_t LPUART\_DRV\_DmaAbortSendingData ( uint32\_t instance )**

Parameters

|                 |                                 |
|-----------------|---------------------------------|
| <i>instance</i> | The LPUART module base address. |
|-----------------|---------------------------------|

Returns

Whether the abort of transmitting was successful or not.

Return values

|                                            |                                           |
|--------------------------------------------|-------------------------------------------|
| <i>kStatus_LPUART_Success</i>              | The transmit was successful.              |
| <i>kStatus_LPUART_NoTransmitInProgress</i> | No transmission is currently in progress. |

**40.3.4.7 lpuart\_status\_t LPUART\_DRV\_DmaReceiveDataBlocking ( uint32\_t instance, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )**

## LPUART Peripheral driver

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or kStatus\_LPUART\_Success.

#### 40.3.4.8 `lpuart_status_t LPUART_DRV_DmaReceiveData ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize )`

### Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                    |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received. |
| <i>rxSize</i>   | The number of bytes to receive.                                    |

### Returns

An error code or kStatus\_LPUART\_Success.

#### 40.3.4.9 `lpuart_status_t LPUART_DRV_DmaGetReceiveStatus ( uint32_t instance, uint32_t * bytesRemaining )`

### Parameters

|                        |                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPUART module base address.                                                                                      |
| <i>bytes-Remaining</i> | A pointer to a value that populated with the number of bytes which still need to be received in the active transfer. |

Returns

Current receiving status.

Return values

|                               |                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | The receive has completed successfully.                                                                                        |
| <i>kStatus_LPUART_Rx-Busy</i> | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

#### 40.3.4.10 `lpuart_status_t LPUART_DRV_DmaAbortReceivingData ( uint32_t instance )`

Parameters

|                 |                                 |
|-----------------|---------------------------------|
| <i>instance</i> | The LPUART module base address. |
|-----------------|---------------------------------|

Returns

Whether the abort of receiving was successful or not.

Return values

|                                             |                                      |
|---------------------------------------------|--------------------------------------|
| <i>kStatus_LPUART_Success</i>               | The receive was successful.          |
| <i>kStatus_LPUART_No-TransmitInProgress</i> | No receive is currently in progress. |

#### 40.3.4.11 `lpuart_status_t LPUART_DRV_Init ( uint32_t instance, lpuart_state_t * lpuartStatePtr, const lpuart_user_config_t * lpuartUserConfig )`

The caller provides memory for the driver state structures during initialization. The user must select the LPUART clock source in the application to initialize the LPUART.

## LPUART Peripheral driver

### Parameters

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <i>instance</i>          | LPUART instance number                                                    |
| <i>lpuartUser-Config</i> | user configuration structure of type <a href="#">lpuart_user_config_t</a> |
| <i>lpuartStatePtr</i>    | pointer to the LPUART driver state structure                              |

### Returns

An error code or `kStatus_LPUART_Success`

#### 40.3.4.12 `lpuart_status_t LPUART_DRV_Deinit ( uint32_t instance )`

This function disables the LPUART interrupts, the transmitter and receiver, and flushes the FIFOs (for modules that support FIFOs).

### Parameters

|                 |                        |
|-----------------|------------------------|
| <i>instance</i> | LPUART instance number |
|-----------------|------------------------|

### Returns

An error code or `kStatus_LPUART_Success`

#### 40.3.4.13 `lpuart_rx_callback_t LPUART_DRV_InstallRxCallback ( uint32_t instance, lpuart_rx_callback_t function, uint8_t * rxBuff, void * callbackParam, bool alwaysEnableRxIrq )`

### Note

After a callback is installed, it bypasses part of the LPUART IRQHandler logic. Therefore, the callback needs to handle the indexes of `txBuff` and `txSize`.

### Parameters

|                 |                             |
|-----------------|-----------------------------|
| <i>instance</i> | The LPUART instance number. |
|-----------------|-----------------------------|

|                           |                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------|
| <i>function</i>           | The LPUART receive callback function.                                                                 |
| <i>rxBuff</i>             | The receive buffer used inside IRQHandler. This buffer must be kept as long as the callback is alive. |
| <i>callbackParam</i>      | The LPUART receive callback parameter pointer.                                                        |
| <i>alwaysEnable-RxIrq</i> | Whether always enable receive IRQ or not.                                                             |

Returns

Former LPUART receive callback function pointer.

**40.3.4.14** `lpuart_tx_callback_t LPUART_DRV_InstallTxCallback ( uint32_t instance, lpuart_tx_callback_t function, uint8_t * txBuff, void * callbackParam )`

Note

After a callback is installed, it bypasses part of the LPUART IRQHandler logic. Therefore, the callback needs to handle the indexes of txBuff and txSize.

Parameters

|                      |                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------|
| <i>instance</i>      | The LPUART instance number.                                                                            |
| <i>function</i>      | The LPUART transmit callback function.                                                                 |
| <i>txBuff</i>        | The transmit buffer used inside IRQHandler. This buffer must be kept as long as the callback is alive. |
| <i>callbackParam</i> | The LPUART transmit callback parameter pointer.                                                        |

Returns

Former LPUART transmit callback function pointer.

**40.3.4.15** `lpuart_status_t LPUART_DRV_SendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout )`

Blocking means that the function does not return until the transmission is complete.

## LPUART Peripheral driver

### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | LPUART instance number                                 |
| <i>txBuff</i>   | source buffer containing 8-bit data characters to send |
| <i>txSize</i>   | the number of bytes to send                            |
| <i>timeout</i>  | timeout value for RTOS abstraction sync control        |

### Returns

An error code or kStatus\_LPUART\_Success

#### 40.3.4.16 **lpuart\_status\_t LPUART\_DRV\_SendData ( uint32\_t instance, const uint8\_t \* txBuff, uint32\_t txSize )**

This enables an a-sync method for transmitting data. When used with a non-blocking receive, the LPUART can perform a full duplex operation. Non-blocking means that the function returns immediately. The application has to get the transmit status to know when the transmit is complete.

### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>instance</i> | LPUART instance number                                 |
| <i>txBuff</i>   | source buffer containing 8-bit data characters to send |
| <i>txSize</i>   | the number of bytes to send                            |

### Returns

An error code or kStatus\_LPUART\_Success

#### 40.3.4.17 **lpuart\_status\_t LPUART\_DRV\_GetTransmitStatus ( uint32\_t instance, uint32\_t \* bytesRemaining )**

### Parameters

|                 |                        |
|-----------------|------------------------|
| <i>instance</i> | LPUART instance number |
|-----------------|------------------------|

|                        |                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------|
| <i>bytes-Remaining</i> | Pointer to value that is populated with the number of bytes that have been sent in the active transfer |
|------------------------|--------------------------------------------------------------------------------------------------------|

Returns

The transmit status.

Return values

|                               |                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_LPUART_TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> will be filled with the number of bytes that have been transmitted so far. |

#### 40.3.4.18 **lpuart\_status\_t LPUART\_DRV\_AbortSendingData ( uint32\_t instance )**

Parameters

|                 |                        |
|-----------------|------------------------|
| <i>instance</i> | LPUART instance number |
|-----------------|------------------------|

Returns

Whether the aborting is successful or not.

#### 40.3.4.19 **lpuart\_status\_t LPUART\_DRV\_ReceiveDataBlocking ( uint32\_t instance, uint8\_t \* rxBuff, uint32\_t rxSize, uint32\_t timeout )**

Blocking means that the function does not return until the receive is complete.

Parameters

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <i>instance</i> | LPUART instance number                                |
| <i>rxBuff</i>   | buffer containing 8-bit read data characters received |
| <i>rxSize</i>   | the number of bytes to receive                        |
| <i>timeout</i>  | timeout value for RTOS abstraction sync control       |

## LPUART Peripheral driver

### Returns

An error code or `kStatus_LPUART_Success`

#### 40.3.4.20 `lpuart_status_t LPUART_DRV_ReceiveData ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize )`

This enables an a-sync method for receiving data. When used with a non-blocking transmission, the LPUART can perform a full duplex operation. Non-blocking means that the function returns immediately. The application has to get the receive status to know when the receive is complete.

### Parameters

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <i>instance</i> | LPUART instance number                                |
| <i>rxBuff</i>   | buffer containing 8-bit read data characters received |
| <i>rxSize</i>   | the number of bytes to receive                        |

### Returns

An error code or `kStatus_LPUART_Success`

#### 40.3.4.21 `lpuart_status_t LPUART_DRV_GetReceiveStatus ( uint32_t instance, uint32_t * bytesRemaining )`

### Parameters

|                        |                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | LPUART instance number                                                                                          |
| <i>bytes-Remaining</i> | pointer to value that is filled with the number of bytes that still need to be received in the active transfer. |

### Returns

The receive status.

Return values

|                               |                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | the receive has completed successfully.                                                                                        |
| <i>kStatus_LPUART_Rx-Busy</i> | the receive is still in progress. <i>bytesReceived</i> will be filled with the number of bytes that have been received so far. |

**40.3.4.22** `lpuart_status_t LPUART_DRV_AbortReceivingData ( uint32_t instance )`

Parameters

|                 |                        |
|-----------------|------------------------|
| <i>instance</i> | LPUART instance number |
|-----------------|------------------------|

Returns

Whether the receiving was successful or not.

**40.3.4.23** `lpuart_status_t LPUART_DRV_EdmaInit ( uint32_t instance, lpuart_edma_state_t * lpuartEdmaStatePtr, const lpuart_edma_user_config_t * lpuartUserConfig )`

This function initializes the run-time state structure to keep track of the on-going transfers, un-gates the clock to the LPUART module, initializes the module to user-defined settings and default settings, configures the IRQ state structure and enables the module-level interrupt to the core, and enables the LPUART module transmitter and receiver. This example shows how to set up the `lpuart_edma_state_t` and the `lpuart_user_config_t` parameters and how to call the `LPUART_DRV_EdmaInit` function by passing in these parameters:

```
lpuart_user_config_t lpuartConfig;
lpuartConfig.baudRate = 9600;
lpuartConfig.bitCountPerChar = kLpuart8BitsPerChar;
lpuartConfig.parityMode = kLpuartParityDisabled;
lpuartConfig.stopBitCount = kLpuartOneStopBit;
lpuart_edma_state_t lpuartEdmaState;
LPUART_DRV_EdmaInit(instance, &lpuartEdmaState, &lpuartConfig);
```

Parameters

---

## LPUART Peripheral driver

|                            |                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>            | The LPUART instance number.                                                                                                                                                                                                                    |
| <i>lpuartEdma-StatePtr</i> | A pointer to the LPUART driver state structure memory. The user passes in the memory for the run-time state structure. The LPUART driver populates the members. This run-time state structure keeps track of the current transfer in progress. |
| <i>lpuartUser-Config</i>   | The user configuration structure of type <a href="#">lpuart_user_config_t</a> . The user populates the members of this structure and passes the pointer of this structure into this function.                                                  |

Returns

An error code or `kStatus_LPUART_Success`.

### 40.3.4.24 `lpuart_status_t LPUART_DRV_EdmaDeinit ( uint32_t instance )`

This function disables the LPUART-DMA trigger, the transmitter, and the receiver.

Parameters

|                 |                             |
|-----------------|-----------------------------|
| <i>instance</i> | The LPUART instance number. |
|-----------------|-----------------------------|

Returns

An error code or `kStatus_LPUART_Success`.

### 40.3.4.25 `lpuart_status_t LPUART_DRV_EdmaSendDataBlocking ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize, uint32_t timeout )`

Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPUART instance number.                                             |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send.     |
| <i>txSize</i>   | The number of bytes to send.                                            |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

Returns

An error code or `kStatus_LPUART_Success`.

### 40.3.4.26 `lpuart_status_t LPUART_DRV_EdmaSendData ( uint32_t instance, const uint8_t * txBuff, uint32_t txSize )`

Parameters

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                     |
| <i>txBuff</i>   | A pointer to the source buffer containing 8-bit data chars to send. |
| <i>txSize</i>   | The number of bytes to send.                                        |

Returns

An error code or `kStatus_LPUART_Success`.

**40.3.4.27** `lpuart_status_t LPUART_DRV_EdmaGetTransmitStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPUART module base address.                                                                            |
| <i>bytes-Remaining</i> | A pointer to a value that is populated with the number of bytes that are remaining in the active transfer. |

Returns

Current transmit status.

Return values

|                               |                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | The transmit has completed successfully.                                                                                              |
| <i>kStatus_LPUART_TxBusy</i>  | The transmit is still in progress. <i>bytesTransmitted</i> is filled with the number of bytes which are transmitted up to that point. |

**40.3.4.28** `lpuart_status_t LPUART_DRV_EdmaAbortSendingData ( uint32_t instance )`

Parameters

|                 |                                 |
|-----------------|---------------------------------|
| <i>instance</i> | The LPUART module base address. |
|-----------------|---------------------------------|

## LPUART Peripheral driver

### Returns

Whether the abort of transmitting was successful or not.

### Return values

|                                            |                                           |
|--------------------------------------------|-------------------------------------------|
| <i>kStatus_LPUART_Success</i>              | The transmit was successful.              |
| <i>kStatus_LPUART_NoTransmitInProgress</i> | No transmission is currently in progress. |

#### 40.3.4.29 `lpuart_status_t LPUART_DRV_EdmaReceiveDataBlocking ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize, uint32_t timeout )`

### Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                         |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received.      |
| <i>rxSize</i>   | The number of bytes to receive.                                         |
| <i>timeout</i>  | A timeout value for RTOS abstraction sync control in milliseconds (ms). |

### Returns

An error code or `kStatus_LPUART_Success`.

#### 40.3.4.30 `lpuart_status_t LPUART_DRV_EdmaReceiveData ( uint32_t instance, uint8_t * rxBuff, uint32_t rxSize )`

### Parameters

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <i>instance</i> | The LPUART module base address.                                    |
| <i>rxBuff</i>   | A pointer to the buffer containing 8-bit read data chars received. |

|               |                                 |
|---------------|---------------------------------|
| <i>rxSize</i> | The number of bytes to receive. |
|---------------|---------------------------------|

Returns

An error code or `kStatus_LPUART_Success`.

#### 40.3.4.31 `lpuart_status_t LPUART_DRV_EdmaGetReceiveStatus ( uint32_t instance, uint32_t * bytesRemaining )`

Parameters

|                        |                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------|
| <i>instance</i>        | The LPUART module base address.                                                                                      |
| <i>bytes-Remaining</i> | A pointer to a value that populated with the number of bytes which still need to be received in the active transfer. |

Returns

Current receiving status.

Return values

|                               |                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>kStatus_LPUART_Success</i> | The receive has completed successfully.                                                                                        |
| <i>kStatus_LPUART_Rx-Busy</i> | The receive is still in progress. <i>bytesReceived</i> is filled with the number of bytes which are received up to that point. |

#### 40.3.4.32 `lpuart_status_t LPUART_DRV_EdmaAbortReceivingData ( uint32_t instance )`

Parameters

|                 |                                 |
|-----------------|---------------------------------|
| <i>instance</i> | The LPUART module base address. |
|-----------------|---------------------------------|

Returns

Whether the abort of receiving was successful or not.

## LPUART Peripheral driver

Return values

|                                            |                                      |
|--------------------------------------------|--------------------------------------|
| <i>kStatus_LPUART_Success</i>              | The receive was successful.          |
| <i>kStatus_LPUART_NoTransmitInProgress</i> | No receive is currently in progress. |

### 40.3.5 Variable Documentation

40.3.5.1 LPUART\_Type\* const g\_lpuartBase[LPUART\_INSTANCE\_COUNT]

40.3.5.2 LPUART\_Type\* const g\_lpuartBase[LPUART\_INSTANCE\_COUNT]

40.3.5.3 LPUART\_Type\* const g\_lpuartBase[LPUART\_INSTANCE\_COUNT]

## 40.4 LPUART Type Definitions

This section describes the LPUART type definitions.

### 40.4.1 LPUART Overview

The LPUART peripheral driver transfers data to and from external devices on the Low Power Universal Asynchronous Receiver/Transmitter (LPUART) serial bus. It provides a method to transmit or receive buffers of data with a single function call.

### 40.4.2 LPUART Device structures

The driver uses instantiations of the `lpuart_tx_state_t` and the `lpuart_rx_state_t` structure to maintain the current state of a particular LPUART instance module driver. The user is required to provide memory for the driver state structures during the initialization. The driver itself does not statically allocate memory.

### 40.4.3 LPUART Initialization

1. To initialize the LPUART driver, call the `LPUART_DRV_Init()` function and pass the instance number of the relevant LPUART peripheral. For example, to use LPUART0 pass a value 0 to the initialization function.
2. Pass a user configuration structure `lpuart_user_config_t` as shown here:

```
// LPUART configuration structure
typedef struct LpuartUserConfig {
 uint32_t baudRate;
 lpuart_parity_mode_t parityMode;
 lpuart_stop_bit_count_t stopBitCount;
 lpuart_bit_count_per_char_t bitCountPerChar;
} lpuart_user_config_t;
```

Typically the user configures the `lpuart_user_config_t` instantiation as an 8-bit-char, no-parity, 1-stop-bit (8-n-1) with a baud rate of 9600 bps. The `lpuart_user_config_t` instantiation can be modified to configure the LPUART peripheral to a different baud rate or character transfer features. This is a code example to set up a user LPUART configuration instantiation:

```
lpuart_user_config_t lpuartConfig;
lpuartConfig.baudRate = 9600;
lpuartConfig.bitCountPerChar = kLpuart8BitsPerChar;
lpuartConfig.parityMode = kLpuartParityDisabled;
lpuartConfig.stopBitCount = kLpuartOneStopBit;
```

### 40.4.4 LPUART Transfers

The driver implements transmit and receive functions to transfer buffers of data by blocking and non-blocking modes.

## LPUART Type Definitions

The blocking transmit and receive functions include `LPUART_DRV_SendDataBlocking()` and the `LPUART_DRV_ReceiveDataBlocking()` functions.

The non-blocking (async) transmit and receive functions include the `LPUART_DRV_SendData()` and the `LPUART_DRV_ReceiveData()` functions.

When using DMA to transfer data, ensure that the data is consistent when there is cache for memory. This means, when reading/ writing the data from/to memory, the application should ensure that data from or to the memory device is not cached.

In all these cases, the functions are interrupt-driven.

## Chapter 41

# LP Trusted Cryptography (LTC)

### 41.1 Overview

The Kinetis SDK provides both HAL and Peripheral drivers for the LT Trusted Cryprography (LTC) module of Kinetis devices.

LP Trusted Cryptography contains multiple cryptographic hardware accelerator engines. The hardware acceleration is available for AES, DES and public key cryptography operations such as modular arithmetic functions , as well as elliptic curve functions, for both integer and binary polynomial field versions.

### Modules

- [LTC HAL driver](#)
- [LTC driver](#)

## Overview

### 41.1.1 LTC AES driver

#### 41.1.1.1 Overview

This section describes the programming interface of the LTC AES driver.

#### Macros

- #define [LTC\\_AES\\_BLOCK\\_SIZE](#) 16  
*AES block size in bytes.*
- #define [LTC\\_AES\\_IV\\_SIZE](#) 16  
*AES IV size in bytes.*
- #define [FSL\\_LTC\\_FIFO\\_SZ\\_MAX\\_DOWN\\_ALGN](#) (0xff0u)  
*LTC module FIFO size in bytes aligned down to the AES block boundary.*
- #define [FSL\\_LTC\\_CCM\\_TAG\\_IDX](#) 8  
*For CCM encryption, the encrypted final MAC is written to the context word 8-11.*
- #define [FSL\\_LTC\\_GCM\\_TAG\\_IDX](#) 0  
*For GCM encryption, the encrypted final MAC is written to the context word 0-3.*
- #define [LTC\\_DRV\\_aes\\_decrypt\\_ctr](#)(instance, input, inputSize, counter, key, keySize, output, counterlast, szLeft) [LTC\\_DRV\\_aes\\_ctr](#)(instance, input, inputSize, counter, key, keySize, output, counterlast, szLeft)  
*AES CTR decrypt is mapped to the AES CTR generic operation.*
- #define [LTC\\_DRV\\_aes\\_encrypt\\_ctr](#)(instance, input, inputSize, counter, key, keySize, output, counterlast, szLeft) [LTC\\_DRV\\_aes\\_ctr](#)(instance, input, inputSize, counter, key, keySize, output, counterlast, szLeft)  
*AES CTR encrypt is mapped to the AES CTR generic operation.*

#### Enumerations

- enum [ltc\\_drv\\_aes\\_key\\_t](#) {  
  [kLtcEncryptKey](#) = 0U,  
  [kLtcDecryptKey](#) = 1U }  
*Type of AES key for ECB and CBC decrypt operations.*

#### Functions

- void [LTC\\_DRV\\_SetDPAMaskSeed](#) (uint32\_t instance, uint32\_t mask)  
*Sets the DPA Mask Seed register.*
- [ltc\\_status\\_t](#) [LTC\\_DRV\\_aes\\_generate\\_decrypt\\_key](#) (uint32\_t instance, const uint8\_t \*encryptKey, uint8\_t \*decryptKey, uint32\_t keySize)  
*Transforms an AES encrypt key (forward AES) into the decrypt key (inverse AES).*
- [ltc\\_status\\_t](#) [LTC\\_DRV\\_aes\\_encrypt\\_ecb](#) (uint32\_t instance, const uint8\_t plaintext[16], const uint8\_t \*key, uint32\_t keySize, uint8\_t ciphertext[16])  
*Encrypts AES using the ECB block mode.*
- [ltc\\_status\\_t](#) [LTC\\_DRV\\_aes\\_decrypt\\_ecb](#) (uint32\_t instance, const uint8\_t ciphertext[16], const uint8\_t \*key, uint32\_t keySize, [ltc\\_drv\\_aes\\_key\\_t](#) keyType, uint8\_t plaintext[16])

- Decrypts AES using ECB block mode.*

  - `ltc_status_t LTC_DRV_aes_encrypt_ecb` (uint32\_t instance, const uint8\_t \*plaintext, uint32\_t inputSize, uint8\_t iv[LTC\_AES\_IV\_SIZE], const uint8\_t \*key, uint32\_t keySize, uint8\_t \*ciphertext)
- Encrypts AES using CBC block mode.*

  - `ltc_status_t LTC_DRV_aes_decrypt_cbc` (uint32\_t instance, const uint8\_t \*ciphertext, uint32\_t inputSize, uint8\_t iv[LTC\_AES\_IV\_SIZE], const uint8\_t \*key, uint32\_t keySize, `ltc_drv_aes_key_t` keyType, uint8\_t \*plaintext)
- Decrypts AES using CBC block mode.*

  - `ltc_status_t LTC_DRV_aes_ctr` (uint32\_t instance, const uint8\_t \*input, uint32\_t inputSize, uint8\_t counter[16], const uint8\_t \*key, uint32\_t keySize, uint8\_t \*output, uint8\_t counterlast[16], uint32\_t \*szLeft)
- Encrypts or decrypts AES using CTR block mode.*

  - `ltc_status_t LTC_DRV_aes_encrypt_tag_gcm` (uint32\_t instance, const uint8\_t \*plaintext, uint32\_t inputSize, const uint8\_t \*iv, uint32\_t ivSize, const uint8\_t \*aad, uint32\_t aadSize, const uint8\_t \*key, uint32\_t keySize, uint8\_t \*ciphertext, uint8\_t \*tag, uint32\_t tagSize)
- Encrypts AES using GCM block mode.*

  - `ltc_status_t LTC_DRV_aes_decrypt_tag_gcm` (uint32\_t instance, const uint8\_t \*ciphertext, uint32\_t inputSize, const uint8\_t \*iv, uint32\_t ivSize, const uint8\_t \*aad, uint32\_t aadSize, const uint8\_t \*key, uint32\_t keySize, uint8\_t \*plaintext, const uint8\_t \*tag, uint32\_t tagSize)
- Decrypts AES using GCM block mode.*

  - `ltc_status_t LTC_DRV_aes_encrypt_tag_ccm` (uint32\_t instance, const uint8\_t \*plaintext, uint32\_t inputSize, const uint8\_t \*iv, uint32\_t ivSize, const uint8\_t \*aad, uint32\_t aadSize, const uint8\_t \*key, uint32\_t keySize, uint8\_t \*ciphertext, uint8\_t \*tag, uint32\_t tagSize)
- Encrypts AES using CCM block mode.*

  - `ltc_status_t LTC_DRV_aes_decrypt_tag_ccm` (uint32\_t instance, const uint8\_t \*ciphertext, uint32\_t inputSize, const uint8\_t \*iv, uint32\_t ivSize, const uint8\_t \*aad, uint32\_t aadSize, const uint8\_t \*key, uint32\_t keySize, uint8\_t \*plaintext, const uint8\_t \*tag, uint32\_t tagSize)
- Decrypts AES using CCM block mode.*

### 41.1.1.2 Enumeration Type Documentation

#### 41.1.1.2.1 enum ltc\_drv\_aes\_key\_t

Enumerator

- ***kLtcEncryptKey*** Input key is an encrypt key (the same key which has been used for encrypt operation)
- ***kLtcDecryptKey*** Input key is a decrypt key (the key has been obtained from `LTC_DRV_aes_generate_decrypt_key()`).

### 41.1.1.3 Function Documentation

#### 41.1.1.3.1 void LTC\_DRV\_SetDPAMaskSeed ( uint32\_t instance, uint32\_t mask )

The DPA Mask Seed register reseeds the mask that provides resistance against DPA attacks on AES keys.

## Overview

Differential Power Analysis Mask (DPA) resistance uses a randomly changing mask that introduces "noise" into the power consumed by the AESA. This reduces the signal-to-noise ratio that differential power analysis attacks use to "guess" bits of the AES key. This randomly changing mask should be seeded at POR, and continues to provide DPA resistance from that point on. However, to provide even more DPA protection it is recommended that the DPA mask be reseeded after every 50,000 AESA blocks have been processed. At that time, software can opt to write a new seed (preferably obtained from an RNG) into the DPA Mask Seed register (DPAMS), or software can opt to provide the new seed earlier or later, or not at all. DPA resistance continues even if the DPA mask is never reseeded.

Parameters

|                 |                             |
|-----------------|-----------------------------|
| <i>instance</i> | LTC module instance number. |
| <i>mask</i>     | The DPA mask seed.          |

### 41.1.1.3.2 `ltc_status_t LTC_DRV_aes_generate_decrypt_key ( uint32_t instance, const uint8_t * encryptKey, uint8_t * decryptKey, uint32_t keySize )`

Transforms the AES encrypt key (forward AES) into the decrypt key (inverse AES). The key derived by this function can be used as a direct load decrypt key for AES ECB and CBC decryption operations (keyType argument).

Parameters

|     |                   |                                                                       |
|-----|-------------------|-----------------------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                                           |
|     | <i>encryptKey</i> | Input key for decrypt key transformation                              |
| out | <i>decryptKey</i> | Output key, the decrypt form of the AES key.                          |
|     | <i>keySize</i>    | Size of the input key and output key in bytes. Must be 16, 24, or 32. |

Returns

Status from key generation operation

### 41.1.1.3.3 `ltc_status_t LTC_DRV_aes_encrypt_ecb ( uint32_t instance, const uint8_t plaintext[16], const uint8_t * key, uint32_t keySize, uint8_t ciphertext[16] )`

Encrypts AES using the ECB block mode.

Parameters

|     |                   |                                                         |
|-----|-------------------|---------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                             |
|     | <i>plaintext</i>  | Input single block (128-bits) of plain text to encrypt  |
|     | <i>key</i>        | Input key to use for encryption                         |
|     | <i>keySize</i>    | Size of the input key, in bytes. Must be 16, 24, or 32. |
| out | <i>ciphertext</i> | Output single block (128-bits) of cipher text           |

**Returns**

Status from encrypt/decrypt operation

**41.1.1.3.4** `ltc_status_t LTC_DRV_aes_decrypt_ecb ( uint32_t instance, const uint8_t ciphertext[16], const uint8_t * key, uint32_t keySize, ltc_drv_aes_key_t keyType, uint8_t plaintext[16] )`

Decrypts AES using ECB block mode.

**Parameters**

|     |                   |                                                                                            |
|-----|-------------------|--------------------------------------------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                                                                |
|     | <i>ciphertext</i> | Input single block (128-bits) of cipher text to decrypt                                    |
|     | <i>key</i>        | Input key to use for encryption                                                            |
|     | <i>keySize</i>    | Size of the input key, in bytes. Must be 16, 24, or 32.                                    |
|     | <i>keyType</i>    | Input type of the key (allows to directly load decrypt key for AES ECB decrypt operation.) |
| out | <i>plaintext</i>  | Output single block (128-bits) of plain text                                               |

**Returns**

Status from encrypt/decrypt operation

**41.1.1.3.5** `ltc_status_t LTC_DRV_aes_encrypt_cbc ( uint32_t instance, const uint8_t * plaintext, uint32_t inputSize, uint8_t iv[LTC_AES_IV_SIZE], const uint8_t * key, uint32_t keySize, uint8_t * ciphertext )`

LTC\_DRV\_aes\_encrypt\_cbc

## Overview

### Parameters

|     |                   |                                                             |
|-----|-------------------|-------------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                                 |
|     | <i>plaintext</i>  | Input plain text to encrypt                                 |
|     | <i>inputSize</i>  | Size of input data in bytes. Must be multiple of 16 bytes.  |
|     | <i>iv</i>         | Input initial vector to combine with the first input block. |
|     | <i>key</i>        | Input key to use for encryption                             |
|     | <i>keySize</i>    | Size of the input key, in bytes. Must be 16, 24, or 32.     |
| out | <i>ciphertext</i> | Output cipher text                                          |

### Returns

Status from encrypt/decrypt operation

**41.1.1.3.6** `ltc_status_t LTC_DRV_aes_decrypt_cbc ( uint32_t instance, const uint8_t * ciphertext, uint32_t inputSize, uint8_t iv[LTC_AES_IV_SIZE], const uint8_t * key, uint32_t keySize, ltc_drv_aes_key_t keyType, uint8_t * plaintext )`

### LTC\_DRV\_aes\_decrypt\_cbc

#### Parameters

|     |                   |                                                                                            |
|-----|-------------------|--------------------------------------------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                                                                |
|     | <i>ciphertext</i> | Input cipher text to decrypt                                                               |
|     | <i>inputSize</i>  | Size of input data in bytes. Must be multiple of 16 bytes.                                 |
|     | <i>iv</i>         | Input initial vector to combine with the first input block.                                |
|     | <i>key</i>        | Input key to use for decryption                                                            |
|     | <i>keySize</i>    | Size of the input key, in bytes. Must be 16, 24, or 32.                                    |
|     | <i>keyType</i>    | Input type of the key (allows to directly load decrypt key for AES CBC decrypt operation.) |
| out | <i>plaintext</i>  | Output plain text                                                                          |

### Returns

Status from encrypt/decrypt operation

**41.1.1.3.7 ltc\_status\_t LTC\_DRV\_aes\_ctr ( uint32\_t *instance*, const uint8\_t \* *input*, uint32\_t *inputSize*, uint8\_t *counter*[16], const uint8\_t \* *key*, uint32\_t *keySize*, uint8\_t \* *output*, uint8\_t *counterlast*[16], uint32\_t \* *szLeft* )**

Encrypts or decrypts AES using CTR block mode. AES CTR mode uses only forward AES cipher and same algorithm for encryption and decryption. The only difference between encryption and decryption is that, for encryption, the input argument is plain text and the output argument is cipher text. For decryption, the input argument is cipher text and the output argument is plain text.

Parameters

|         |                    |                                                                                                               |
|---------|--------------------|---------------------------------------------------------------------------------------------------------------|
|         | <i>instance</i>    | LTC module instance number.                                                                                   |
|         | <i>input</i>       | Input data for CTR block mode                                                                                 |
|         | <i>inputSize</i>   | Size of input data in bytes                                                                                   |
| in, out | <i>counter</i>     | Input counter (updates on return)                                                                             |
|         | <i>key</i>         | Input key to use for forward AES cipher                                                                       |
|         | <i>keySize</i>     | Size of the input key, in bytes. Must be 16, 24, or 32.                                                       |
| out     | <i>output</i>      | Output data for CTR block mode                                                                                |
| out     | <i>counterlast</i> | Output cipher of last counter, for chained CTR calls. NULL can be passed if chained calls are not used.       |
| out     | <i>szLeft</i>      | Output number of bytes in left unused in counterlast block. NULL can be passed if chained calls are not used. |

Returns

Status from encrypt/decrypt operation

**41.1.1.3.8 ltc\_status\_t LTC\_DRV\_aes\_encrypt\_tag\_gcm ( uint32\_t *instance*, const uint8\_t \* *plaintext*, uint32\_t *inputSize*, const uint8\_t \* *iv*, uint32\_t *ivSize*, const uint8\_t \* *aad*, uint32\_t *aadSize*, const uint8\_t \* *key*, uint32\_t *keySize*, uint8\_t \* *ciphertext*, uint8\_t \* *tag*, uint32\_t *tagSize* )**

Encrypts AES using GCM block mode. If plaintext is NULL, only the GHASH is calculated and output in the 'tag' field.

Parameters

---

## Overview

|     |                   |                                                                             |
|-----|-------------------|-----------------------------------------------------------------------------|
|     | <i>instance</i>   | LTC module instance number.                                                 |
|     | <i>plaintext</i>  | Input plain text to encrypt                                                 |
|     | <i>inputSize</i>  | Size of input data in bytes                                                 |
|     | <i>iv</i>         | Input initial vector                                                        |
|     | <i>ivSize</i>     | Size of the IV                                                              |
|     | <i>aad</i>        | Input additional authentication data                                        |
|     | <i>aadSize</i>    | Input size in bytes of AAD                                                  |
|     | <i>key</i>        | Input key to use for encryption                                             |
|     | <i>keySize</i>    | Size of the input key, in bytes. Must be 16, 24, or 32.                     |
| out | <i>ciphertext</i> | Output cipher text.                                                         |
| out | <i>tag</i>        | Output hash tag. Set to NULL to skip tag processing.                        |
|     | <i>tagSize</i>    | Input size of the tag to generate, in bytes. Must be 4,8,12,13,14,15 or 16. |

## Returns

Status from encrypt/decrypt operation

**41.1.1.3.9** `ltc_status_t LTC_DRV_aes_decrypt_tag_gcm ( uint32_t instance, const uint8_t * ciphertext, uint32_t inputSize, const uint8_t * iv, uint32_t ivSize, const uint8_t * aad, uint32_t aadSize, const uint8_t * key, uint32_t keySize, uint8_t * plaintext, const uint8_t * tag, uint32_t tagSize )`

Decrypts AES using GCM block mode. If ciphertext is NULL, only the GHASH is calculated and compared with the received GHASH in 'tag' field.

## Parameters

|  |                   |                              |
|--|-------------------|------------------------------|
|  | <i>instance</i>   | LTC module instance number.  |
